## ***Disclaimer/Warning/Caveat***

Do not consult these pages unless you agree not to hold the author or publisher liable for any errors or omissions. The uses are given as they are found in the literature, and from translations of the common names. The information **is not recommended** for use. These data are compiled to provide an idea of what people have used the plants for, and some (but not all) of the potential impacts on human physiology.

Data were gathered from the literature on botanical, economic, and medical plants, none of which will ever be completely known phytochemically. These data were compiled by a human being from published and personally communicated sources by human beings. Therefore, the originals and the following material **will** contain errors.

For any serious studies, values need to be rechecked and personally obtained for chemical data. Self-diagnosis and self-medication are **not** recommended. Serious scientific studies of plant uses are recommended, but **self-testing is not considered an option**. All plants, like all animals, contain toxins and carcinogens. Even commonly ingested food plants (like bell peppers, peanuts, and strawberries) can cause fatal allergies in sensitive people.

To my wife, Sandra Kay Roderick Austin, for putting up with my innumerable  
idiosyncrasies over the years, and for unfailing support

# ***Foreword***

**James A. Duke**

Economic Botanist, USDA (ret.)

How pleased I was to see the final draft of this marvelous resource, *Florida Ethnobotany*, the culmination of almost a half century of ethnobotanical investigations. The career of Dan Austin is well documented in the introduction, which is fascinating reading. Dan and I are both “graduates” of the Missouri Botanical Garden, so our professional acquaintance goes back about 40 years. We’re both first taxonomists (later ethnobotanists) whose prior training was augmented and enhanced by our horizon-broadening tours of the great Missouri Botanical Garden. I was there, off and on, from 1960 to 1963, benefiting, as did Dan, from exposures to Edgar Anderson, Henry Andrews, Hugh Cutler, Calaway Dodson, Robert Dressler, Fritz Went, and R.E. Woodson. I don’t know about Dan, but I went to Missouri, a very local “yokel,” i.e., a southeastern botanist, trained and well versed in the flora of the Carolinas. But, I came out of Missouri 4 years later, with a much bigger neotropical outlook, better versed in the pantropical flora. In retrospect, I was a post-doc at Missouri before I knew the word postdoctoral.

That tropical experience has rather outweighed my southeastern experience to this day. I now have more than 6 treasured years spent in various parts of tropical America and I became a tropical ethnobotanist (Panama, 1961, 1965–1968) before I myself knew the word *ethnobotany*. That’s why, as an ethnotaxonomist myself, I am so pleased to write this foreword to a book written by an ethnotaxonomist. By agreeing to indulge myself this pleasure, I granted myself yet another indulgence, the ability to get an earlier look at the draft of this long-awaited treasure.

I settled in, searching it immediately, as I was working on the draft of a *Frutal Medicinal Tropical*, my vision of a fruit orchard for Latin America, comprising species that have edible fruits as well as medicinal uses. Dan and I had exchanged views on the importance of colloquial names in Latin America. We both share the view that scientific names are the medium of communication between international ethnotaxonomists, but colloquial names are the means of communication (in addition to sign language) between ethnotaxonomists and their ethnic subjects.

Dan’s text is appropriately based on the premise that “If people in other places use the plants, then people in Florida used them” (Dan Austin). Let me add a corollary that is equally useful and that is the premise of my *Frutal Medicinal Tropical*—“If poor or rich people in Florida can use them, then poorer people, elsewhere in the Caribbean, e.g., Antigua, Belize, Cuba, Dominique, Haiti, and Puerto Rico, can also use them similarly, to good advantage” (Jim Duke). Using his idea, Dan proceeded, and commenced and successfully concluded a comparative study of Florida and the surrounding regions, compiling ethnobotanical and utilization data on the plants that occur, naturally or

naturalized (but not strict cultivars) in Florida. In the process, he compiled his exciting, fascinating, interesting, and utilitarian *Florida Ethnobotany*. His ethnoflora covers almost 900 species with common names, interesting historical accounts, and various uses, from building materials, dyes, foods, fuels, medicines, ornaments, mystical, and ritual. Dan Austin's ethnoflora mentions more than 400 species not covered in Dan Moerman's monumental book (1998), the most recent and complete compilation of plants used by indigenous people in North America (north of Mexico). So Austin nearly doubles the number of utilitarian species reported for Floridian species as reported by Moerman from Florida or elsewhere in North America. Not all of the covered species are restricted to Florida and the Caribbean. Many also occur in other southeastern states. Some are circum-Caribbean or even pantropical.

I'm delighted to report that Dan's text stresses common names (with translations into English when possible) to place the species in their cultural contexts. Dan's emphasis is on people living in Florida, but he makes comparisons with other indigenous people from other areas around that region. I can strongly recommend this book to all biologists, botanists, ethnologists, linguists, tropiphiles (those addicted to the tropics like I am), and yes, even health-care professionals, be they allopathic, alternative, herbal, homeopath, naturopath, nurse, nurse practitioner, ... and yes, even psychopaths. Great reading!

# *Preface*

**Sir Ghilleen T.Prance**

School of Plant Sciences, University of Reading, Reading, U.K.

Given the diversity of peoples from many different backgrounds and the varied history of Florida it is surprising that a comprehensive study of their ethnobotany has not already been written. Ethnobotany is at present a growing and dynamic science so this volume is most timely. It is also good that the author has taken a broad approach to his definition of ethnobotany that includes much more than solely the botany of the indigenous Native American peoples. The result is a comprehensive treatment where comparison can be made between the names and uses of plants by the different peoples of Florida and of neighboring countries. This is a most thoroughly researched work, the contents and the use of which will extend far beyond the boundaries of Florida. It reflects the multiracial composition of the people of Florida where each group has its own ethnobotanical knowledge that has contributed to the vast amount of information that is included here. It also reflects the long history of interaction between Florida and her neighbors. There is a large amount of information about Mexico, the Caribbean, and other parts of the southern United States. As a nonspecialist on the flora of Florida, I not only learned a lot about the botany of the state through reading this fascinating text, but also a great deal about its intriguing history. A work of this magnitude could only have been achieved through the author's lifelong gathering of information and interaction with the flora and the people of Florida. The information given about each genus frequently does not start in Florida. Details of the early history of the nomenclature of species often takes us back to the work of European botanists such as Linnaeus or even earlier in the history of botany. This book combines a wealth of locally gathered information with a comprehensive study of the early literature about each species included.

When a detailed, well-researched ethnobotanical study is made, it highlights the extent to which the population uses a local flora. Details are given here of 814 of the 2654 species of flowering plants believed to be native to Florida and a further 74 have less well-documented uses. Use for 33% of a flora is high and reflects the number of different peoples and traditions that have searched the plant diversity of this tropical and subtropical vegetation to provide for their needs. In the accounts of the genera of useful plants we are taken on a journey from *Abutilon*, the original source of marshmallow, to *Zornia*, a legume that has many medicinal uses especially as a laxative and a diuretic. In between, the variety of local uses for the plants is amazing. I particularly like all the information given about the derivation of names and the large number of different local names that exist for each species. That the local nomenclature is so varied shows the importance of the scientific names as standard fixed references to the species. However, when a list of local names over a wide region is provided, it reveals much about the ethnobotany of the species.

The book is further enhanced by the various personal experiences, interactions, and reflections of the author that are scattered throughout the text. Dan Austin has personally interacted with many of the current ethnobotanists of the world and he has made good use of the information that comes from these discussions. He has also ensured accuracy of the information given here by sending out parts of the text to the world experts on each plant family. This thoroughly researched and well-verified text will be of use to all people interested in plant uses for many years to come.

## Acknowledgments

It is hard to know when I began gathering the data for this book. Probably it started before my recollection of things when my parents and grandparents began teaching me about plants. My collecting had been going on for some time when a friend of the family found me gathering and pressing plants for Gordon Hunter, one of my favorite undergraduate professors. Each time I would bring out a plant to press, she would ask, “But, what good is it?” Mostly, I did not have an answer for her, but I began to learn.

Certainly, this book began forming the day David M. McJunkin walked into my office in 1970. I had just moved to Florida after working in Belém, Brazil and St. Louis, Missouri. It was difficult adjusting to southern Florida, as it was a life between the real tropics of Brazil and the temperate zone of St. Louis. David was an undergraduate in the Geography Department at Florida Atlantic University, who introduced himself by handing me an interlibrary loan article that I had requested some weeks before. If I remember correctly, I asked him who in thunder he was, and what in blazes he was doing with *my* material. However, I doubt I used those exact words in asking. Whatever his reply, we began our acquaintance by comparing our shared interest in people and plants. He had an amateur’s knowledge of the technical aspects of plants, but he was an expert at finding and recognizing different kinds in the field. After some years of working together, with him sharing his knowledge and experience with geography and anthropology, and I mine on plants, we published “An Ethnoflora of Chokoloskee Island, Collier County, Florida” (Austin and McJunkin 1978). So far as I am aware, we coined the word “ethnoflora.” I most recently have seen “our word” in a chapter title in David Yetman’s book *The Guarjios of the Sierra Madre* (2002).

About 1970, my graduate major professor, Walter H. Lewis, had become interested in ethnobotany—a topic I had incorporated into my dissertation. He and his wife, Memory Elvin-Lewis, published their *Medical Botany: Plants Affecting Man’s Health* (Lewis and Elvin-Lewis 1977). Also, while I was at the Missouri Botanical Garden, Edgar Anderson and Hugh Cutler had shown great interest in those topics, and I always gleaned everything I could from them long before the topic came in vogue.

Before I began teaching plant taxonomy in the spring of 1970, I realized that the way I was taught was not going to work. Therefore, I began incorporating people and their relationships with plants into my course. In 31 years of teaching, I had only a handful of individuals who came into the course with an avowed interest in plants. Yet, most of them left my class proclaiming a new interest in the green world around them.

All of these interactions were enhanced by studies of the morning glories, the Convolvulaceae. I credit Walter Lewis for directing me into examining that group, while admitting my reluctance. At the time Walter suggested morning glories, I was fascinated with the mints. Walter’s suggestion was, as always, excellent.

It is impossible to study the morning glories and not become entangled in their interactions with people. Temperate people, knowing only the bindweeds (*Convolvulus*

*arvensis*), usually vehemently hate the plants. Tropical people, who know morning glories under different conditions, dislike some, but love others. It was through studies of the genus *Ipomoea* that I worked in the tropics and gathered a more complete appreciation of how people outside Florida lived with plants. *Camotes* (sweet potatoes or yams to many, *Ipomoea batatas*) surely has the longest and most intimate association with people.

The experience working with David McJunkin made me realize how little was recorded on Florida ethnobotany. Later, Mike Duever, then of the Audubon Society, asked me to talk about the “Environmental Effects of the Glades Indians on Southern Florida.” The talk was at the March 1980 meeting of the Association of Southeastern Biologists and the Ecological Society of America. Gathering information for that meeting in Tampa prompted me to formalize much of the information I had gathered on pre-European Glades people. The talk was not only well received at that meeting, but a version of it was so popular that it was given at least annually for the next 20 years.

Somewhere along the line, I met Cameron Donaldson, editor of *The Palmetto*, the newsletter of the Florida Native Plant Society. As I had been contributing to that publication since its beginning, Cammie and I got along well. Then, at a symposium organized for the meeting of the Florida Native Plant Society in Miami in 2000, Brad Bennett asked me to give a talk on uses by indigenous people. Specifically, he wanted me to talk about the Glades people since he was to talk about the Seminoles. Standing in the wings listening was Cammie Donaldson, and afterward she asked me to write on the topic for *The Palmetto*. I selected from the many possible plants, one of the least known and rarest in the southern end of the state. We published “Chiggery Grape. Discovering Florida’s Ethnobotany. The People and Plant Interactions Series” (*The Palmetto* 20:6–9, 2000). It was an article that turned into a series. As I write this, the ninth piece is due off the Florida Native Plant Society presses.

It was with due prodding and cajoling from both Cammie and Kathy Craddock Burks (Florida Department of Environmental Protection) that I began thinking about turning all the data I had collected into a longer collection. As I thumbed through Dick Wunderlin’s *Guide to the Vascular Plants of Florida* (1998) to make the list of species in Florida that had been used, I almost decided against it. The list seemed endless.

Still, when I compared my list of species that had been used with Dan Moerman’s for North America (Moerman 1998), I realized the enormous gap remaining. Therefore, I began working on the manuscript soon after leaving Florida in August of 2001.

From 1970 until now hundreds of people have helped, educated, corrected, and aided me in countless ways. Prominent among them, since 2000, are the following individuals. I thank all of you for what you taught me!

Mary Adair (University of Kansas, Lawrence)—*Chenopodium* and archaeology Jonathan D. Amith (Yale University, New Haven, CT)—Náhuatl words Henrik Balslev (University of Aarhus, Hinnerup, Denmark)—Danish names Mardie Banks (Florida Atlantic University, Boca Raton, FL)—Graphics, and genius combined with boundless energy in helping with computer-enhanced images

Bradley C. Bennett (Florida International University, Tamiami Campus, Miami)—Many hours of discussion about all sorts of topics relating to Florida plants and their relationships to people there and elsewhere

Joanne L. Birch (The University of Texas, Austin)—For introducing me to the work of Dr. Gideon Lincecum and his studies of the southeastern tribes

Anthony R. Brach (Missouri Botanical Garden and Harvard University Herbaria, Cambridge, MA)—Saururaceae

Keith A. Bradley (The Institute for Regional Conservation, Miami, FL)—Rare southern Florida plants

George Aaron Broadwell (University at Albany, SUNY, Albany, NY)—Choctaw

Rick Brusca (Arizona-Sonora Desert Museum, Tucson, AZ)—Support by the museum

Alberto Burquez Montijo (Universidad Nacional Autónoma de Mexico, Hermosillo, Sonora)—Mexican plant names

Steve Cafferty (Natural History Museum, London)—Linnaean names

Michael Chamberland (Cheekwood Botanical Garden, Nashville, TN)—Cactaceae

Shih-Huei Chen (National Hualien Teachers College, Hualien, Taiwan)—*Stachytarpheta*

Fernando Chiang (Universidad Nacional Autónoma de Mexico, D.F.)—*Lycium*

Deborah J. Clifton (University of Louisiana, Lafayette)—Southeastern languages

Mireya Correa (University of Panama and Smithsonian Tropical Research Institute, Canal Zone)—Panamanian names

Walter Courtenay (Professor Emeritus, Gainesville, FL)—Fishes

Melissa Darby (Portland, OR)—Archaeology and etymology of languages

Anne Cox (Lake Wales Ridge State Forest, Frostproof, FL)—Annonaceae, particularly *Asimina*

Kathy Craddock-Burks (Florida Department of Environmental Protection, Tallahassee)—Plants of northern Florida

Gerrit Davidse (Missouri Botanical Garden, St. Louis, MO)—Mesoamerican botany

George Diggs (Austin College, Sherman, TX)—Data on species shared with Florida

Scott Zona (Fairchild Tropical Garden, Coral Gables, FL)—Arecaceae

I thank the Florida Native Plant Society for permission to use my articles. Although they have been revised and updated since they first appeared, accounts are based on material first published in the "Discovering Florida's Ethnobotany. The People and Plant Interactions Series" (Austin 2000a, b, 2001a,b, 2002b,c,d,e, 2003). I also have drawn heavily from other papers I published in *The Palmetto* (cf. References).

Illustrations have been taken from several sources, but Penelope Honychurch Billingham (signed PNH) gave permission to use the largest number (103). In addition, line art has been used from the following publications. The 89 illustrations by Priscilla Fawcett were taken from Correll and Correll (1982). Permission has been given by both Sven Koeltz, of Koeltz Scientific Books, Koenigstein, Germany, and Fairchild Tropical Garden to use Priscilla's work. Three other drawings from Correll and Correll (1982) by Gordon W. Dillon (orchids) and Jane W. Roller (*Thelypteris*) are used courtesy of Fairchild Tropical Garden.

Other drawings are used from Bucholtz (1968) with permission of the College of Agricultural, Consumer and Environmental Sciences, University of Illinois. *Tournefortia hisutissima* was used with permission of the Missouri Botanical Garden Press, originally appearing in Nowicke (1969). Illustrations of *Viola* are from Russell (1965), courtesy of the Botanical Research Institute of Texas, Fort Worth. John C. Semple provided his original drawings of *Chrysopsis* and *Pityopsis*. Aquatic plant drawings are used with permission of the University of Florida Center for Aquatic Plants (Gainesville). University of Arizona Press gave permission to use L.B. Hamilton's drawing of *Trianthema*.

Numerous drawings are from Britton and Brown (1896–1898), Sargent (1905), and Hitchcock and Chase (1950). Drawings by Vivian Frazier are from Correll and Correll (1972), and those by Regina O. Hughes are from Reed (1971). Beryl Simpson kindly gave permission to reproduce the drawing of *Krameria* by M.C. Ogorzaly. Shih-Huei Chen permitted the use of his drawing of *Stachytarpheta*. The illustration of *Iva annua* is from Tournefort (1823). Two drawings are pre-Columbian: *Zea* was skillfully adapted by Mardie Banks from Fuchs (1542); *Zephyranthes* is from Morrison (1699).

All of the photographs except three were taken by the author. *Alvaradoa* was provided by Thomas R. Van Devender. *Cucurbita okeechobeensis* was contributed by Terrance Walters and Deena Deckert-Walters. David N. Neubauer kindly permitted use of the photograph of *Torreya*.

Last, but not least, I thank four outstanding individuals at CRC Press for their kind assistance and help preparing the manuscript for the printer: Christine Andreasen, Donna Coggeshall, Pat Roberson, and John Sulzycki.

**Daniel F. Austin**

## *The Author*

**Daniel F. Austin, Ph.D.**, is a Research Associate of the Fairchild Tropical Garden, Coral Gables, Florida, and the Arizona-Sonora Desert Museum, Tucson, Arizona. He is also an Adjunct Professor, Department of Plant Sciences, University of Arizona, Tucson; a Research Associate in the Department of Biological Sciences, Florida International University, Miami; a Research Associate at the Desert Botanical Garden, Phoenix, Arizona; a Research Associate at the Drylands Institute, Tucson; and an Emeritus Professor at Florida Atlantic University, Boca Raton.

Dr. Austin attended graduate school at Washington University and Missouri Botanical Garden, St. Louis, Missouri, where he worked with Walter H. Lewis. He received his M.A. in 1969 and his Ph.D. in 1970, and then spent 31 years teaching in the Florida State University System. While in Florida, he received three Green Palmetto Awards and the Mentor Award from the Florida Native Plant Society, the Outstanding Member Award from the Florida Exotic Pest Plant Council, and was named Environmental Champion by NatureScaping at the Earth Day Celebration in 2001. He also serves as Technical Advisor to The Nature Conservancy, Office of Endangered Species, Tallahassee; he is on the Advisory Board of The Wildflower Society, Florida and Caribbean Region, Delray Beach; he is part of the South Florida Ecosystem Recovery Strategy Team and Recovery Team Member for *Cereus eriophorus*, U.S. Fish and Wildlife Service, Vero Beach; and he is on the Sweetpotato Crop Germplasm Committee on Sweet Potato, U.S. Department of Agriculture, Beltsville, Maryland.

Dr. Austin is a Fellow of the Linnaean Society of London and a member of the International Association of Plant Taxonomists and the Society for Economic Botany. He has served the Society for Economic Botany as Book Review Editor (1992-present), as a Council Member (1993–1996), a member of the Publications (1992-present) and Publicity Committees, and in other capacities. He has published 7 books, 45 book chapters, 120 research papers, and 67 popular articles, plus numerous book reviews and abstracts. After taking an early retirement, he moved to Arizona to continue his studies. His current research focuses on the ethnobotany of plant species shared between the Caribbean and northwestern Mexico and adjacent United States, and on the systematics and evolution of the Convolvulaceae.

# People and Plants

## Introduction

Florida was the first mainland region north of Mexico to be explored and settled by Europeans. Although there have been individual studies of plants used by the inhabitants of Florida (Austin 1980, 1997, Larson 1980, Hann 1986), no synthesis has ever been made of this pivotal region in the history of New World exploration. That fact is especially remarkable because Florida supports one of the richest floras in North America, combining temperate and tropical elements. Perhaps part of the reason Florida has been neglected botanically is because the Spanish explorers failed to find large native populations that might be exploited for mining and food production. The Spaniards also failed to find people who had large quantities of precious metals (Hudson et al. 1989). Another factor is doubtless that the early records were sequestered in Spain for centuries.

Juan Ponce de León set foot on the peninsula on 2 April 1513 and named it *La Florida* because it was the *Pascua de flores* or *Pascua florida*, the Easter season (Bloodworth and Morris 1978, García-Pelayo y Gross 1980). Although officially discovered in 1513, there are tantalizing bits of historical evidence that the peninsula was known well before then (e.g., Williams [1837] 1962, Quinn 1955, Hudson 1975). For example, the “Cantino” map of 1502 shows a decidedly Florida-like peninsula extending toward the Antilles (Jane and Skelton 1960). Probably because the Spanish were so jealous of their newly acquired lands, little became known about them during the period between 1513 and 1763 outside Spain’s inner circle of the Crown, the Church, and the economic elite.

The first expedition to explore *La Florida* was led by Pánfilo de Narváez in 1528. That venture was followed by the more famous one led by Hernándo de Soto in 1539. Spanish chronicles of those events remained in Madrid for centuries, and the limited information they contained about people and plants have comparatively recently become available (e.g., Swanton 1939). One of the few available early commentaries on Florida plants was by Nicholas Monardes in 1569, translated by John Frampton in 1577.

The first British survey was by German-born William G. DeBrahm, who became surveyor general of East Florida in 1764 (DeVorse in DeBrahm [1775] 1971). DeBrahm began the job on 11 February 1765, and it lasted until October 1770. In 1771, he was recalled to England to stand charges levied against him by East Florida’s governor James Grant (DeVorse in DeBrahm [1775] 1971). DeBrahm and Grant had argued over essentially everything from the time they met in St. Augustine. DeBrahm started negotiating to publish his work as early as 1769, and it appeared in two books—*The Atlantic Pilot* ([1772] 1974), and his *Report of the General Survey in the Southern District of North America* ([1775] 1971).

Bernard Romans, born in Holland, but partly educated in England, also surveyed Florida for the British (Romans [1775] 1961). He was sent to America in 1755 as a civil engineer. Between 1760 and 1770 he was the deputy surveyor of Georgia, and then he went to East Florida as a surveyor of Lord Egmont’s estates on Amelia Island and the St. Johns River. From 1769–1770 he was appointed as chief deputy surveyor for the Southern District and the first commander of vessels in service, at first working for DeBrahm. This position allowed him to go (at his own expense) to the Bahamas and the

west coast of Florida as far as Pensacola, where he arrived in 1771. When Peter Chester, governor of West Florida, discovered that Romans was proficient in botany, he became the king's botanist in the province (Richardson in Romans [1775] 1961).

There were also three significant botanical surveys in the northern part of the state during the British period. The first of these was by John Bartram who, with his son William, explored the St. Johns River in the fall and winter of 1765–1766. However, that account was eclipsed by the journey made by William Bartram between 1773 and 1777, when he traveled alone over much of the same Florida territory he and his father had covered. His *Travels* became a major literary item in Europe and overshadowed much of his father's contributions (Harper 1958). Last, but certainly not least, was the exploration made by the Frenchman André Michaux. Not only did Michaux cover much of the same ground that the Bartrams had in northeastern Florida, but he also found plants neither of them had reported (Taylor and Norman 2002).

The Adams-Onís Treaty of 1821 ceded Florida to the Americans, and General Andrew Jackson was appointed governor. Jackson formalized the old East and West Florida into two counties, Escambia (west of the Suwanee River) and St. Johns (east of the Suwanee River). Shortly afterward, there was a flurry of books promoting this region (e.g., Forbes [1821] 1964, Simmons [1822] 1973, Vignoles [1823] 1977). Captain John LeConte made the first Florida survey in 1822 (Adicks 1978). LeConte propagated the myth that Lake Mayaco, which Fontaneda ([1575] 1944) called Lake Mayaimi (now Lake Okeechobee), did not exist.

The botanical and geographical void of southern Florida is exemplified by people believing that Lake Okeechobee was a myth well past the time when the region became a territory of the United States and on into the mid-1800s. Both DeBrahm and Romans had left some botanical information about the coastal regions and the Florida Keys (Austin 1980), but the interior was a blank. The word “everglades,” now famous as the vast sawgrass marsh that formerly covered much of southern Florida, did not come into existence until 1823. These sparse data, coupled with the fact that the indigenous people of the peninsula had essentially disappeared by the 1760s, allowed little to be recorded of the human use of plants in the region.

### *Methods*

This compilation is a cross-cultural study of plants shared by different floras and peoples. I have used the common names and historical sequence to weave together the more esoteric information about the individual species. Most published studies that include common names do not translate them. That absence makes names mostly or completely inaccessible to many readers. That tendency is certainly understandable, because obtaining translations is time-consuming and difficult. However, omitting meanings of names precludes fantastic glimpses into the ways people's minds work. Sometimes names also show how the individuals fit in the society where they live or give a notion of how those societies function. To me, that is at least as important as any particular use a plant has.

Any study of ethnobotany is destined to be nothing more than a snapshot of the information gathered by a few individuals. No matter how cooperative those involved,

most of what is known is not passed on to the person or persons recording the information. I know from my own childhood that my father and grandfather constantly amazed me with the intricate details they knew of certain plants. I also know that they did not pass all that information on to me. All of our recorded information from any person or people is destined to be incomplete.

With that in mind, I began working in the early 1970s on what the inhabitants of Florida may have been using among the state's plants. The information given here is little more than a glimpse of what those indigenous people, and those who interacted with them, learned and practiced. The following discussion is flawed and incomplete, but it gives what I believe is a better idea of how people used Florida plants than anything currently existing.

Typically, because of a northern European bias, past studies in the United States have examined humans and plants outside of Florida. The newest compilation of human botany in North America by Moerman (1998), as detailed and thick as the volume is, barely touches on what is known about Florida plants. The following discussion picks up where Moerman left off and treats the Florida plants, particularly those of tropical origin.

Since 1967, when I first went to Mexico with Bruce MacBryde and Royce Oliver, I have talked with people in much of the region discussed here. There are only three of the United States—all in New England—that I have not visited in gathering information on plants and people. I have visited Mexico numerous times, with most of the trips concentrating on lands of the Gulf coast, and from Mexico City south. In the Caribbean, I have made excursions to the Bahama Islands, Dominican Republic, Jamaica, Puerto Rico, and Trinidad. Similarly, plants and people were studied in Brazil, Colombia, Ecuador, Guyana, Peru, Suriname, and Venezuela. In Central America I visited only Costa Rica, but I made comparative field studies for an Old World comparison in Australia, Ceylon, Pakistan, Taiwan, and Thailand.

### *The Species*

The species and the scientific names included here were compiled from the flora of Florida (Wunderlin 1998). We do not agree in all cases about the nativity of those species, but mostly we are in accord. Species included in this discussion are those that are probably native to Florida (Table 1 and Table 2). Three groups of species are excluded: (1) those related to species of known Florida usage (Table 3); (2) those related to species known to be used outside Florida (Table 4); and (3) weedy species whose provenance is uncertain, at least to me (Table 5). Those species would surely boost the total to more than the 888 that are recorded, but that inclusion might reflect too many historical changes in usage. Because the story is already complex, adding those other species would make for an even more unwieldy array.

There are three exceptions to the "native" rule. Those deviations are the cultivated *Nicotiana*, *Phaseolus*, and *Zea*. All of these domesticated plants were pivotal in the indigenous cultures, and were firmly established long before Europeans arrived. Any discussion of indigenous use of plants would be incomplete if these three were omitted.

### *Common Names*

The next step was to compile the common names of the species, and the starting point for many plants was comparison with Morton (1981). Because Morton did not give the country of origin of the names she listed, it was necessary to compare them with other sources. Where no country of usage is given for a common name, it usually comes from Morton (1981) and has not been found elsewhere. For trees, there are also some missing provenances from Miller and Wiedenhoeft (2000). Many of the names in Morton (1981) turn out to be incorrectly spelled, and none has the diacritical marks. Some of the names included here may suffer from that same defect, but I have tried to make those corrections.

Primary among the sources for common names were flora and plant lists. Those sources include Chapman (1897), Britton and Brown (1896–1898), Johnston (1909), Standley (1920–1926, 1937), Pittier (1926, 1957), Small (1933), Standley and Record (1936), Fernald (1950), Martínez (1969, 1979), Adams (1972), Boldingh (1909, 1914), Britton and Millspaugh (1920), Leon and Alain (1946–1953, 1957–1963), Goodding et al. (1965), Correll and Johnston (1970), Liogier (1962, 1974), Fournet (1978), Correll and Correll (1982), Liogier and Martorell (1982), Proctor (1984), Kindscher (1987, 1992), Brako et al. (1995), Acevedo-Rodríguez et al. (1996), Diggs et al. (1999), Felger (2000), Felger et al. (2001), Yetman and Van Devender (2001), and Yetman (2002). English names were also sought in Britten and Holland (1886), Clute (1923), and Vickery (1995), although no attempt has been made to include all of the names for any species. In addition to these, searches were made in other literature cited in the text.

Even many of the individuals involved with ethnobotanical research are unaware of the impact that plants have had on our daily speech, regardless of which language we speak. As primarily European culture derivatives, we know most about the English, Spanish, Portuguese, French, and Dutch used in the Americas. History of use, etymology, and sometimes other information are available for several languages in the OED (1971), the Spanish dictionaries by Santamaría and García (1974) and Neves (1975), the dictionary of Portuguese (Ferreira ca. 1978), and French sources by Larousse (1987), Bloch and von Wartburg (1994), and Picoche (1994). Other language resources used were Dwelly (1933), De Vries (1959), Van Goor (1979), and Ragazzini and Biagi (1986). European common names also are listed by Linnaeus ([1749] 1979), Polunin (1969), Pignatti (1982), Polunin and Smythies (1988), Scott (1995), and Mossberg and Stenberg (1994), and Meyer et al. (1999).

Indigenous language names are more problematical. For those, I have used Siméon ([1885] 1981) for Náhuatl, and asked Jonathan Amith to check many of them. Mayan names were translated and put in context by my friend José Luis Tapia-Muñoz and his colleagues. Taino names were taken largely from Coll y Toste (1972). Tupí names were found in Sampaio (1970) and Ferreira (ca. 1978). A few Carib names are from Aublet (1775), but most came from Hodge and Taylor (1957) and Klooster et al. (2003).

Names for plants in indigenous languages of the United States were taken primarily from Hunter ([1823] 1973), Gatschet (1877, 1878, 1880), Mooney (1885–1886), Dorsey and Swanton (1912), Loughridge and Hodge (1914), Gilmore (1919), Gatschet and Swanton (1932), La Flesche (1932), Speck (1934), Vestal and Schultes (1939), Haas (1940), Geary (1955), Mahr (1955a, b), Sturtevant (1955), Feeling (1975), Siebert (1975),

Crawford (1978), Daniels-Sakim (1983), Howard (1984), Sylestine et al. (1993), Kimball (1994), Munro and Willmond (1994), Drechsel (1997), Martin and Mauldin (2000), Snow and Stans (2001), and Rudes and Costa (2003). A large problem exists with publications by nonbotanists because most made no great effort to identify plants. English common names are usually all that are given for identifications, and these are often impossible to combine with the proper species. Many indigenous names of plants were omitted because I could not identify them.

No attempt has been made to bring the Muskogean words into line with the alphabet that has been adopted (e.g., Daniels-Sakim 1983, Martin and Mauldin 2000, Snow and Stans 2001). Instead, it seems more instructive to reproduce the spellings as they appear in the original sources. In fact, Snow and Stans (2001) have done exactly that by using the Creek alphabet for Creek names, but the English alphabet for those in Mikasuki. Spellings for Muskogee are those given in Loughridge and Hodge (1914), Howard (1984), and Martin and Mauldin (2000). Similarly, names from other languages are presented as they were found.

Common names are wonderfully mercurial. The words change shape and pronunciation depending not only on who says them, but also on who writes them. I have attempted to combine names that seem to be the same by including the variants within brackets. For example, *cihuapatli* [*ciguapazle*, *cihuapastle*, *ciguapaztle*] is the Náhuatl name and some variants derived from it for *Chromolaena odorata*. In most cases, I have tried to list a “correct” spelling first, and include the variants later. With many words adopted into American Spanish, they have been accompanied by a variant spelling or at least pronunciation. That is certainly true for Náhuatl words, and surely is the same for the hundreds of other languages that have come into contact with Spanish. The same must be true for French and Dutch.

English names come in an amazing variety of forms because our language is as eclectic in adopting and incorporating foreign words as the Aztecs were with religions (Soustelle 1962). Enriching that complexity are the wonderful additions that people of African heritage have made to what seems to be English. Sometimes the “English” spoken in the Caribbean is called British West Indian (or simply BWI) because of the syntactical and rhythmic alterations that they have used to replace those known to native English speakers, whether of British or American stock.

Apparently, the same kinds of changes have been made in Creole French and Dutch. Those who wrote down the names surely wrote what they heard, but the spellings are so beautifully imaginative that people with European languages as their first language sometimes have no idea what they are. My main consultant for French names, Richard Moyroud, fluent in continental French, often simply said he had no idea, or that there was no such word. When he could not tell me what the names meant, often Penny Honychurch could. Her years of experience with Creole French in Dominica enabled her to “interpret” many words for me. When they failed, Fabienne Taylor often translated them.

At times, I was able to decipher Creole French and Dutch names, not because I know French or Dutch, but because I do not. I simply pronounced them to myself and looked them up in a dictionary. Sometimes that process worked; sometimes it did not. For example, it took me some time to realize that the names for *Capsicum annuum* given as *piment zouézeau* or *piment zouézo* were based on *oiseau* for “bird,” as in “bird pepper.”

Comparatively little is known about the indigenous languages, and only a small percentage of ethnographic studies with botanical components bothered to learn the meanings of local language names. Outstanding among those that *have* recorded these instructive data are those by Alcorn (1984) and Felger and Moser (1985). Frustrating in its fragmentary translations of common names is the otherwise fine study by Messer (1978).

Although many of the species have long lists of common names, those given here are but a sample of those in use for most species. A number of other sources give other names, including Britten and Holland (1886), Bergen (1892–1898), and Clute (1923). Van Wijk (1909–1916) has devoted three enormous volumes to listing common names in four languages. Similarly, de Cleene and Lejeune (2002) give many names in Dutch, English, French, and German.

### *Spelling and Pronunciation*

Each language has its own rules governing pronunciation, and there is insufficient space to summarize them here. Instead, a few of the conventions used for special sounds in select languages are provided.

#### **Cherokee (Mooney 1885–1886, Feeling 1976, Moondove 1997)**

**u** or **v** as in English *gun*, nasalized to **unh**; **do:-tsu** (*Fraxinus*) and **ujilv?i** (*Gossypium*).

**'** indicates accent on the syllable that it follows; when following a consonant it means that the vowel has been omitted; **a'-tsi-na'** (*Juniperus*).

**?** within a word or at the end is a glottal stop, as the sound in English *oh'oh*; **wa-ne?-i** (*Carya*) and **ujilv?i** (*Gossypium*).

**:** indicates that the vowel is long and takes twice as long to say; **so:hi** (*hickory nut*).

Letters in parentheses are sometimes omitted from everyday speech; **sa'-l(i)** (*Diospyros*).

#### **Chickasaw (Munro and Willmond 1994)**

**'** indicates a glottal stop, as the sound in English *oh'oh*; **ampohko'li'** (*Campsis radicans*).

**ʃ** has no equivalent in English, but is near *thl* as in English *fifthly*, **pitʃhi'**, *thistle*; also in Alabama, Choctaw, Creek, Koasati, and Mikasuki.

**Chinantec, Paya, Tarahumara (Lipp 1971, Bye 1986, Lentz 1993)**

?within a word or at the end is a glottal stop, as the sound in English *oh'oh*; Paya, *á?á* (*Zea mays*), Tarahumara, *wum ka?* (*Capsicum annuum*).

Superscript numbers indicate tones, as in Chinantec *hyni<sup>3</sup>* (*Phaseolus vulgaris*).

θ is a voiceless fricative, resembling “th” in English; Chinantec, *ku θow* (*Zea mays*).

**Choctaw (Haag and Willis 2001)**

o indicates nasalization; *hat<sub>o</sub> falaha* (*Allium*).

ʔ has no equivalent in English, but is near *thl* as in English *fif<sub>thly</sub>*; *ʔali*, “to pour”; also in Alabama, Chickasaw, Creek, Koasati, and Mikasuki.

**Mikasuki (Sturtevant 1955, Martin and Mauldin 2000)**

A phonetic transcription was created by Mary R. Haas in the 1930s and 1940s specifically for use with the Muskogean languages. Sturtevant (1955) used his own modification of this method. Neither Bennett (1997) nor Snow and Stans (2001) used this transcription.

*asaykho:mi:ci* (*Acer rubrum*). Written by Snow and Stans as *ashak homeche*.

~ indicates nasalization; *cafā:mcó:bî* (*Cicuta maculata*).

ʔ has no equivalent in English, but is near *thl* as in English *fif<sub>thly</sub>*; *otā:ni* /*orā:ni*/ “cane”; also in Alabama, Chickasaw, Choctaw, Creek, Koasati.

**Muskogee/Creek (Martin and Mauldin 2000)**

In these Muskogee examples, the phonetic transcription follows the word but is included within //. It should be pointed out that Sturtevant was inconsistent in spelling. For example, he spelled “medicine” as both *hiliswa* and *hiliswā*, even on the same page, e.g., 514. I have followed his rendition as nearly as possible.

**v** as in English *ago*; **yce** /aci/ “corn”

**e** as in English *if*; **ecke** /icki/ “his/her mother”

**u** as in English *put*; **fuswv** /fōswa/ “bird”

**a** as in English *father*; **afke** /ā:fki/ “hominy grits”

**o** as in English *rode*; **ofv** /ó:fa/ “inside”

**c** as in English *inch*; **gesse** /cissi/ “mouse”

ʔ has no equivalent in English, but is near *thl* as in English *fif<sub>thly</sub>*, *ʔto* /ʔto/ “fish”; also in Alabama, Chickasaw, Choctaw, Koasati, and Mikasuki.

### *Format*

Each genus or group of species within a genus forms an entry. Rarely are there two entries for a genus (e.g., Milkweed and *Asclepias*). When this occurs, the information in one did not fit comfortably with the others. Within the discussion, there is an introduction to the group, with some history, including etymology of generic and specific names. This is followed by uses, beginning with general uses such as wood, fuel, weaving materials, food, and then medicine. In many cases, some of the chemical and bioactive properties are given. The uses are given first by indigenous tribes when endemic to the New World. Where genera or species are shared, they are first introduced as the Europeans would have known them about the time of discovery. Indigenous uses then follow. To bring the information to the present, a few key discussions are presented from as near New World discovery as possible, and then more toward the present.

Entries are in two formats. Usually tropical species are introduced with a common name, and discussed briefly. In the discussion, the other common names that reveal similar views and concepts are grouped and discussed together. The common names for most of the temperate species are listed in alphabetical order, and the discussion follows. These two types of entries emphasize the tropical vs. temperate affinities, but they are not mutually exclusive. Although some species are tropical, so little information about them is available that they are handled like the temperate taxa. Available information was the overriding factor.

Where possible, the origins of the common names are given in historical perspective. Since little of that information is available for most languages, there is a dominance of English, French, and German chronologies of forms and varied meanings.

Rarely, synonyms follow the accepted binomial. These are included only in cases where it seems likely that there may be confusion, and to eliminate the problem of having to look up the names in Wunderlin (1998) or in Wunderlin and Hansen (2002), which is updated as changes become known. Because neither of these sources contains historical information on genera, those data were taken from TROPICOS ([www.mobot.mobot.org](http://www.mobot.mobot.org)). Type information, when discussed, was cross-checked with Wunderlin and Hansen (2002) and with the Linnaean Herbarium and Linnaean Typification Projects Web sites. Both Linnaean databases are at [www.nhm.ac.uk](http://www.nhm.ac.uk).

Historically important individuals are cited with their full names and dates of birth and death in the first entry. Afterward, some of those who are well known are abbreviated to their last names. Some commentary on their nationalities and where these scientists worked is provided for a more complete view of the international effort that produced the current understanding of these plants. Although Linnaeus named the great majority of plants now growing within the political boundaries of Florida, scientists from around the world have been involved in their collection, naming, and current arrangement into taxonomic categories. This international effort makes for a complex ethnobotany layer superimposed on the strata already in place among indigenous people when the New World was rediscovered by the Old in 1492.

## *Definitions*

### **Florida—Then and Now**

The geographic delimitation of “Florida” used here is the current political unit, and not the limits used in the past. Over the centuries, the delimitation of “Florida” has varied considerably.

From the first known Spanish maps of the 1500s, the entire eastern coast of North America was labeled *La Florida*. For example, the Kerrigan translation of Barrientos’s ([1567] 1965) original Spanish says that, “Florida has a promontory which extends a hundred leagues into the sea and narrows to a cape called Head of the Martyres.... On the east is the Land of Cod and Newfoundland; to the west, New Spain; to the north, China and Tartary.” The region called *los Martires* we now know as the Florida Keys. “*Nueva España*” was the viceroyalty (from 1521–1821) including land now in the southwestern United States, Mexico, and Central America to Panama. Thus, *la Florida* extended from Mexico to Newfoundland in Canada.

The region is labeled to conform with this idea on the Gerónimo de Chaves’s map believed to date from the second half of the 16th century (Milanich and Milbrath 1989). Some maps gave added detail, as in Diego Rivero’s 1529 map, which shows the *Tierra de Ayllón* in what is now coastal Georgia and the Carolinas. That region was named for Santo Domingo’s royal judge Lucas Vásquez de Ayllón’s attempt at colonization in 1526 (Milanich and Milbrath 1989).

However, by the time the Spanish relinquished the region to the English in 1763, the British colonies of Georgia and the Carolinas had been separated from the southern region. The crown also created the colony of East Florida and appointed James Grant, a hero of the Cherokee War, as its royal governor. Thus, by 1763, Florida was divided into “West Florida” (what is now called the Panhandle) and “East Florida” (the peninsula), with the two divided by the Suwanee River.

British rule of Florida lasted until 1783, when again Spain became the official governing country. However, during the 20-year period when Britain held the land, two major surveys were commissioned (DeBrahm [1775] 1971, Romans [1775] 1961). Spain formally ceded Florida to the United States in 1821. Then, in 1845, Florida was admitted to the Union (Bloodworth and Morris 1978).

### **Ethnobotany**

The term “ethnobotany” has been defined and discussed many times since it was created by John Harshberger in 1895. I find unacceptable even the most recent discussions of the term, such as those published by Schultes and Reis (1995), Balick and Cox (1996), Cotton (1996), and Wickens (2000). All of those definitions take a “Eurocentric” view that I find prejudiced by assigning ethnobotany to the study of “traditional” people. I submit that we are all “traditional” in one way or another.

Although those authors using that definition tried to avoid the Caucasian bias expressed from Harshberger in 1895 to Schultes and Reis (1995), they have simply substituted another word for “primitive.” Instead, my view of the discipline of ethnobotany is the complete and total study of people and plants. I taught a course for

almost 30 years using that definition. However, when the class was team-taught at Arizona State University in Tempe with Wendy Hodgson and Gary Nabhan there was no consensus on the definition.

### *Florida's Lost Ethnobotany*

People everywhere in the world use some percentage of the flora. A problem in discussing this usage is how to determine the extent to which plants are used. Some have suggested complicated ways of analyzing the data statistically (Moerman 1991). Others think that a more straightforward method is simply to look at the percentage of species used in each area (Yarnell 1964, Griffin 1967). However crude the percentage method, it provides one estimate of how plants were used. For many reasons, estimates are always below actual utilization.

Griffin (1967) thought that at least North American cultures used about 20% of the available species. That was the percentage used by natives of the Upper Great Lakes and by the earliest inhabitants of one island in southwestern Florida (Yarnell 1964, Austin and McJunkin 1978). Because Austin and McJunkin (1978) found a percentage that matched the one reported by Yarnell (1964) and Griffin (1967), one aspect of this investigation will be to "test" the 20% theory against a more rigorous data set. Early examination showed that the data for indigenous groups contained markedly fewer than the predicted numbers (Austin 1980, 1997, Hann 1991). Those reports also made it clear that the data for indigenous use of Florida plants were unusually fragmentary. Therefore, examination of a broader sample of people was needed.

### *The Florida People*

The Florida peninsula north of Lake Okeechobee was populated by two large cultural groups when Europeans arrived. In the region around what is now Tallahassee (*tulwa*, town, *ahassee*, old, Creek) were the Apalachee (*apelachi*, allies, Choctaw). These were Muskogean people, from whom the Appalachian Mountains received their name. To their west were Choctaws, such as the Pensacola (*pan-sha*, hair, *okla*, people) (Swanton 1946, Simpson 1956).

Occupying most of the Florida peninsula were the people called the Timucua, from *atimoqua* (lord or ruler), in their language (Swanton 1946). Typically, the Timucua are divided into the Eastern and the Western Timucuan. The Western group included the *Acuera* (*acu*, moon or all, *ero*, year, Timucua) of the modern Ocala region south of Gainesville, the *Ocale* [*Cale*, *Ocali*] (meaning uncertain; *cale* is fruit in Timucua, *kali* is spring in Choctaw), the *Tocobago* (maybe "place where gourds are produced," Choctaw) around Tampa Bay, and the *Utina* (powerful, Timucua), between the Santa Fe and Suwanee Rivers. Eastern groups included the *Saturiwa* [*Saturibe*] on the upper St. Johns River, and the *Surruque* [*Horruque*, *Serropé*, *Surreche*] in the Cape Canaveral region (Swanton 1946). In total, there were 14 "Provinces," interpreted as tribes (Milanich 1975).

Some include the *Ais* of Indian River as part of the Timucuan, while others consider them related to the Glades people (cf. Milanich 1975). Most of what has been recorded of the Timucua language was published by Gatschet (1877–1880). Their language was, according to most, a distinct linguistic group. Swanton (1946), as usual, considered them “undoubtedly a branch of the great Muskogean stock,” as he did almost everyone in the southeast. Reflecting modern understanding, Drechsel (1997) and Martin and Mauldin (2000) considered Timucua linguistically isolated. These people were virtually extinct by the 1740s (Swanton 1946, Simpson 1956, Tebeau 1968, Hudson 1976).

Archaeologists have called the first residents of southern Florida the “Glades Indians” (Goggin and Sturtevant 1964), in spite of the fact that they lived along the coasts and not in the Everglades (cf. maps in Swanton 1946, Milanich 1975). The Glades people met the Spanish when they arrived in 1513, and they preceded the Seminoles in the region. It was a Glades arrow that killed Ponce de León when he landed and tried to capture them for slaves (Douglas 1947, Hudson 1976).

The Glades people consisted of tribes or villages usually called *Ais* (“deer”), *Jaega* [*Jobé*, *Hobe*], *Tekesta* [*Chequescha*, *Tequesta*], *Calusas* (“fierce people”), and *Miamis* (“big lake”) (Goggin and Sturtevant 1964). Fontaneda ([1575] 1944) recorded that dialects of those in the south and southwest he could understand, but the *Ais* and *Jaega* speech was linguistically distinct and he could not understand it. In spite of Fontaneda’s comments, Swanton (1946) believed the five major groups spoke essentially one language. Only 11 words are known from their languages (Milanich and Proctor 1978, Austin 1997), so the point is moot.

Native populations declined rapidly after European contact, partly because of their enslavement by the English and Spanish, but mostly because of introduced diseases (Crosby 1972, Hann 1991). By 1763, Glades people were culturally extinct (Romans [1775] 1961, Hudson 1976, Sturtevant 1978). Because the Glades and Timucua cultures disappeared so quickly, little was recorded about their use of plants. We have only sketches from Le Moyne (1564), Fontaneda ([1575] 1944), Laudonnière ([1586] 1928), Dickinson in 1699 (Andrews and Andrews 1945), and Spanish priests (Hann 1986, 1991) as first-hand visitors, along with the archaeological record (e.g., Gilliland 1975, Hogan 1978, Milanich and Fairbanks 1980, Sears 1982). Much of what is known about utilization of plants has been summarized recently (Austin 1980, 1997).

During the 1600s and 1700s, the Glades people regularly moved in canoes between the Keys and Cuba (Barcia 1951, Sturtevant 1978). These southern Florida natives had ample opportunity to learn Spanish when they were in contact with priests and their accompanying escorts, during the time they spent in Havana, and when they visited *rancherías* along Florida coasts. Knowledge of that language led to their also being called “Spanish Indians” (for summary, see Austin and McJunkin 1978). Contact with Cubans for so long surely led to exchange of information regarding plants.

When Florida changed from rule by the Spanish to the British in 1763, the region had largely been depopulated by disease, slaving, and transplanting of people to Cuba (Swanton 1946). Into the unpopulated regions left by the demise of the Timucua and Glades peoples, groups of Muskogean began emigrating under pressure from the north. People now called the Miccosukee (“Mikasuki” now applies only to the language) were among the first to move down the peninsula and populate empty southern Florida after the Second Seminole War (1835–1842). Ancestors of the Miccosukee were the the

Hitichiti of southern Georgia (Swanton 1946, Simpson 1956, Tebeau 1968, Hudson 1976). Martin and Mauldin (2000) called their language the Hitichiti-Mikasuki. These people were followed by Creeks who spoke variants of Muskogee, with that spoken on the Brighton Reservation on the north end of Lake Okeechobee formerly being called “Cow Creek” (Sturtevant 1955). This I have called “Creek” following the terminology of Snow and Stans (2001). Their relatives in Oklahoma still speak Muskogee, and the two are similar enough that they can mostly understand each other (Snow and Stans 2001). DeBrahm ([1775] 1971), Romans ([1775] 1961), and both Bartrams, but especially William Bartram ([1791] 1958), left some information on the early Muskogean of northern Florida.

However, well into the 1800s people dubbed the “Spanish Indians” remained in southern Florida. Goggin (1940), Swanton (1946), and Sturtevant (1953, 1978) considered these Spanish-speaking people as remnant Glades tribes. Older literature calls them “Calusas.” One of the “Spanish Indians” was *Chakaika* [*Chekika*]. He and his followers lived and fought during the Second Seminole War (1835–1842) with Miccosukee leaders *Holatta-Micco* (*holahta*, village headman, *miko*, chief), who was called Billy Bowlegs by the whites, and *Hospetarke* (Mahon 1985). From that association, the Seminoles surely learned new plant uses, and this may be reflected in the data collected by Sturtevant (1955) among the Mikasuki-speaking Seminoles.

### ***Neighboring People***

Historical records confirm that southern Florida people traded with Cuba (Fontaneda [1575] 1944, Barcia 1951). Other historical accounts deal with trading within the eastern United States, in Mexico, and elsewhere. For example, Smith (1933) commented on the Potawatomi trading plant use with the Ojibwa and Menomini. Similarly, Latorre and Latorre (1977) noted how the Kickapoo learned from their neighbors when removed to Coahuila, Mexico. The similarity of uses of many plants within and outside Florida is so great among people of different linguistic stocks that exchange of information seems assured. Indeed, Howard (1968), Walker (1981), and Jackson (2003) suggested that all people in the southeast had “common understandings of cosmology...[and] roughly standard medical practices and ethnobotany.” Therefore, a synoptic introduction is provided to establish where geographically some of the important people were who are mentioned in the species accounts.

Comments on where these people lived at the time of contact are largely taken from Swanton (1946), Grosvenor et al. (1972), Billard (1974), Crawford (1978), Bennett (1982), Garrett et al. (1982), and Drechsel (1997). As Swanton (1946) made clear, the location of virtually all Southeastern tribes changed as they fought with each other and were driven from their native lands by European intrusion. Therefore, no attempt has been made to summarize the locations where these people have lived.

### **Southeastern Tribes**

These are people with whom the Timucua certainly were in contact and surely traded, either directly or indirectly. One example of the trade network in plants is detailed under

Osage orange (see *Maclura*). Although *M. pomifera* is native to Texas, it was traded as far east as Florida and probably reached North Carolina.

Although the groups periodically made war on each other, they continued trading. Arrival of the Europeans finally gave them a common enemy, and some established the Creek Confederacy, also called the Five Civilized Tribes. That political alliance included four Muskogean speakers (the Chickasaw, Choctaw, Creek, Seminole), plus the linguistically distinct Cherokee (Billard 1974, Martin and Mauldin 2000). Bartram ([1791] 1958) recorded the polyglot nature of the region, and Thomas (1954), Callendar (1978), Walker (1981), and Jackson (2003) have shown that some towns in the 1700s included various mixes of Catawba (Siouan-Catawaban), Cherokee (Iroquoian), Creek (Muskogean), Koasati (Muskogean), Natchez (language isolate), Nottoway [Nattaway] (Iroquoian), Shawnee (Algonquian), Tuskegee (Muskogean), and Yuchi (language isolate). Single towns speaking different Algonquian, Iroquoian, Muskogean, and isolated languages existed.

There were many other tribes in the region. In addition to those mentioned below, Swanton (1946) listed most of the others, their fates, population estimates, and other pieces of their history. Billard (1974) gave some of the same data updated. Booker et al. (1992) and Jackson (2003) have most recently provided a glimpse of the complex mixture of people and languages living in the region. Of the hundreds of names given to various villages and tribes in the southeastern United States, only the dominant or best known are listed here. These groups were selected largely because the extant literature on them includes information about plants.

**ALABAMA** [*Alabamu*, *Albama*, *Alebamon*, *Alibama*, *Alibamou*, *Alibamon*, *Allibamou*] (*alba-amo*, “medicine gatherers” or “thicket clearers,” in Choctaw; from *alba*, vegetation, *amo*, clear, collect, gather; Muskogean language family) The tribal legend is that their name came from *alibamu*, “here we rest.” That popular belief stems from a folk etymology given wide currency in the 1850s through the writings of Alexander Beauford Meek. However, the first known use of this derivation appeared earlier in an unsigned article in a July 27, 1842 issue of the *Jacksonville Republican*. There is no linguistic evidence within Muskogean to support such an interpretation (Sylestine et al. 1993). De Soto found these people in 1540 in the northern part of Mississippi, west or northwest of the Chickasaw. However, by 1702, they were living on the Alabama River just below the junction of the rivers Coosa (Elmore County, AL) and Tallapoosa (Haralson County, GA) in what is now central-western Alabama. Most of them now live near Livingston in eastern Texas, and the others live in Louisiana (Sylestine et al. 1993).

**APALACHEE** (people on the other side [of a river], or maybe Choctaw *apalichi*, rulers or allies; Muskogean language family) The first mention of these people was when Narváez and his company were attacked by them in 1528, and the Apalachee were one of the reasons for the Spanish misfortunes. Later, warriors from the Apalachee repelled de Soto and his men from what is now the Tallahassee area in the Florida Panhandle in 1539. These people constantly harassed de Soto’s band from 1 October 1539 until 3 March 1540. The Apalachee were extinct by the late 18th century (Billard 1974), although some families were absorbed into the Creeks (Swanton 1946). Their language was closest to Alabama, Hitichiti-Mikasuki, and Koasati (Kimball 1994).

**APALACHICOLA** [*Palachicola*] (people on the other side [of a river], or people of the ruling place; Muskogean language family) These were Hitichiti-speaking villagers who lived on the lower part of the Chattahoochee [*Cvto-Hocce Hvcce*] (*cvto*, rock, *hocce*, marked, *hvcce*, stream) River. The early usage is vague, but by 1675 and 1686, the name was applied to villages in the Florida Panhandle and nearby southwestern Georgia and southeastern Alabama (Swanton 1946, Billard 1974). Most of them joined the Creek Confederation, with some families joining the Seminoles, and others being removed to Okmulgee, Oklahoma.

**CADDO** (contraction of *Kadohadacho*, true chiefs; Caddoan language family) The Caddoan word *taysa* (friend) was used to name the state we now call Texas. Confusion has it that the state was named with the Spanish word *tejas*, tiles, originally spelled, *texas*, but that is a convergence of sounds in distinct languages (Billard 1974). De Soto encountered one of the tribes, the *Tula*, in southwestern Arkansas in 1541 near the modern Caddo Gap. Others within this linguistic family included the *Hasinai* and the *Natchitoches* (maybe from *nashitosh*, pawpaws), among others. The principal range of the Caddo was in the southwestern corner of Arkansas, and adjacent southeastern Oklahoma, northeastern Texas, and northwestern Louisiana. There were almost 1000 of them living on the Brazos River in 1937.

**CAROLINA ALGONQUIANS** (Algonquian language family) Harriot ([1590] 1972) left most of the little that is known about these people in historic times. Among the groups that he named there, the principal ones are the *Chawanook*, *Secotan*, and *Weapemoc*. In his illustrations he concentrated on people in the towns of *Pomeiooc*, *Pommeioocke*, *Secota*, and *Roanoac*. Swanton (1946) gave a sketch only of the *Weapemoc*. Grosvenor et al. (1972) showed, in addition, the *Croatoan*, *Pamlico*, *Roanoke*, *Secotan*, and some other small groups along the coast. These people remain as the Lumbees (see [www.lumbeetribe.com](http://www.lumbeetribe.com)). This tribe includes remnants of several of the former groups, and has official recognition by North Carolina, but is not recognized federally.

**CATAWBA** (from *yī kátapu*, “people of the fork” [of the river, cf. Young and Siebert 2003]; Siouan-Catawban language family, cf. Oliverio and Rankin 2003) The largest population called themselves *yī í-suwa* [*Nieye, Esaw*] (*yī í*, people [of the], *suwa*, river). The second dialect was spoken by the *yī sá-wa* [*Saraw, Saura, Sauro, Cheraw*] (*yī í*, people [of the], *sá-wa*, peninsula). Their home at the time of contact was in north-central South Carolina and near Augusta, Georgia. Spanish Captain Juan Pardo first encountered them in 1566 under the name *Ysa* [*Yssa*] in Georgia. The next year, he found the *Usi* living in Carolina. The Catawba now live in Oklahoma and South Carolina.

**CHEROKEE** (*tciloki*, people of a different speech, Muskogee; Iroquoian language family) In their own syllabary, created by *Sikwa'yi* [Sequoyah] (ca. 1760–1843), whom the whites called George Gist, Cherokee is rendered *Tsa'lagi* or *Tsa'ragi*, depending on dialect. Mooney (1885–1886) listed about 50 different spellings of “Cherokee” at various times in history. They call themselves the *Yun'wiya* (*yunwi*, people, *ya*, real) (Mooney 1885–1886) also glossed *aniyvwíya'i* (Walker 1981). The Cherokee historically occupied the eastern portion of the Appalachian Mountains in southwestern West Virginia, western North Carolina, and eastern Tennessee (*tanasi*, the Cherokee name of the Little Tennessee River). De Soto may have encountered these people in 1540 near Murphy,

North Carolina; he called their principal town the *Guasili* [*Guasule*; *Cauchi* in Booker et al. 1992] (*savanna*, Catabwa). There are now Cherokee in North Carolina and Oklahoma.

**CHICKASAW** (*chikki*, old, *asha*, to reside, or old residence, Choctaw. Muskogean language family) While most consider theirs a distinct language (Munro and Willmond 1994), others view it as a dialect of Choctaw (Billard 1974). The area from the Jackson Purchase of western Kentucky (planted field, in Iroquoian) south along the Mississippi (big river, in Illinois) River in Tennessee and into northern Alabama and Mississippi was the contact-era region claimed by the Chickasaw. De Soto found them in northeastern Mississippi between the heads of the Tombigbee and Tallahatchie (*etvlwa*, town, *hvcce*, river, Creek) Rivers in 1540. Romans ([1775] 1961) gave a detailed early record of the tribe. Most Chickasaw now live in Oklahoma (cf. *Zea* for treaty and removal).

**CHOCTAW** [*Chata*, *Chactaw*] (they call themselves *Chahta*, river people; Muskogean language family) The largest of the Muskogean-speaking tribes in the southeastern United States, the Choctaw historically occupied parts of Mississippi, Alabama, and Louisiana. De Soto found these people in 1540 but recorded them under the name *Mabilia* (Halbert in Byington et al. 1915 suggested it was from *moeli*, “to paddle,” Choctaw; Drechsel 1997 was doubtful; see *Arundinaria*). Also recorded by the de Soto chronicles are the names *Apafalaya* and *Pafallaya*, both variants of the Choctaw *pans-falaya* for “long hair,” the Pensacola. The name *Pensacola* distinguishes Choctaws from the tribes who had the hair cut short on both sides, leaving only a “roach” or “mohawk” down the middle of the head (Swanton 1931, 1946). Romans ([1775] 1961) commented that the Choctaw were called “Flatheads” because of their modifying skull shape in infancy. The Choctaw, accomplished farmers, now live from Oklahoma east into parts of their former homeland (Swanton 1931, Billard 1974).

**CREEK** (people called “Creeks” originally were named after the Ocheese Creek where they lived; shortened by 1725; that creek, now the Ocmulgee River [from *oke*, water, *mulgee*, place, Hitichiti], is usually translated “where the water boils up”; also called the MUSKOGEE) The Muskogee were the “core” Creeks. It is difficult to estimate the first contact with Creeks because they were so scattered into villages or subdivisions with so many names (see Booker et al. 1992). Perhaps the first were those recorded as *Kasihta* or *Coweta*, who were descended from the *Coosa* (maybe from *koskosa*, the cry of a bird, Creek). All three were reported by de Soto in 1540 as the *Coosa* [*Cosa*, *Coça*]. Various branches of the Creeks occupied most of Georgia, parts of Alabama, and the Panhandle of Florida. Most of their descendants are now in Oklahoma (*okla*, people, *homma*, red, in Choctaw).

**HITICHITI** (possibly from *Atcki-hata*, or *cekhicetv*, to pile up, a name given to the Hitichiti-speaking people by the Lower Creeks; said to refer to a “heap of white ashes piled close to the ceremonial ground”; Muskogean language family) The Hitichiti were originally in south-central Georgia, where they lived on the Altamaha River (*akh*, Choctaw passive, *tamaha*, town), and northern Florida. De Soto found them on the Ocmulgee River and called them the *Ocute* [*Achuse*, *Achusi*, *Ochus*] (*ochisi*, a person speaking a different language). Part of them were removed to Oklahoma with the Creeks and settled near Hitichiti Station and Okmulgee. Those remaining in the east joined the Seminoles, and were partly resettled in the northern part of their territory in Oklahoma. Dreschsel (1997) considered them one of the many linguistically isolated groups in the southeast; others say they are Muskogean (Kimball 1994, Martin and Mauldin 2000).

**HOUMA** (*hooma*, red; probably shortened from Choctaw *shaktei*, crawfish, *homma*, red; linguistically isolated) These were neighbors of the Natchez and lived to their southeast in Louisiana and Mississippi. While de Soto was among the Choctaw in the winter of 1541, he sent a force to attack a nearby tribe they called the *Sacchuma* [*Saquechuma*]. The *Sacchuma* had abandoned and burned their village when the Spanish arrived, so the Europeans actually never saw them. These people were first visited in 1682 by the French priest La Salle, who called them the *Chakchiuma* (*shaktei homma*). In 1682, La Salle's lieutenant Henri de Tonti made an alliance with them. Pierre Le Moyne Iberville, the founder of Louisiana, renewed the agreement in 1699. Today more than 500 members of the United Houma Nation live in Texas with the Alabama (Alabama-Coushatta Tribe of Texas 2003). Dreschel (1997) makes a convincing argument that these were one of the many linguistically isolated groups in the southeast.

**KOASATI** [*Acoste*, *Acosta*, *Coste*, *Costehe*, *Cussatees*, *Cushatta*, *Coushatta*] (perhaps related to Choctaw *konshak*, cane, particularly since they think of themselves as the "White Cane" people; Muskogean language family) De Soto first mentioned these people under the names *Acosta* [*Acoste*], *Coste*, and *Costehe*. They were then living on what is probably Pine Island in the Tennessee River; it has been called "River of the Cussatees." After years of displacement, they finally settled in Louisiana. Most of them still live in Louisiana; others live with the Alabama in Texas (Sylestine et al. 1993, Kimball 1994).

**MICCOSUKEE** (*mikko*, chief, *sukee*, pig, but maybe originally from *niko*, eater, *suki*, pig, because of their taste for introduced Old World swine, *Sus scrofa*; linguistically isolated or Muskogean) After living for many years on the edge of Lake Miccosukee in the Panhandle, these people were driven south by a variety of treaties and battles with the Americans. Today their principal home is the Miccosukee Reservation in southwestern Florida, although there are families scattered up the peninsula. Drechsel (1997) pointed out that Miccosukee is a synonym for Hitichiti, but both terms are retained for clarification.

**MUSKOGEE** (probably from Shawnee *muskiegui*, lake or pond; related to Creek *muskeg*, swamp; Ojibwa *maskig*, swamp; Muskogean language family) See also CREEK.

**NATCHEZ** [*Nah'-Chee*, *Nauche*, *W'Nahk'-Chee*, *Nvce*] ("fast warrior(s)," in their own language) The Natchez (French spelling) language was formerly considered distantly related to Muskogean. Dreschel (1997) and Martin and Mauldin (2000) considered Natchez "a language lacking close relatives." De Soto first learned about these people in 1542 when he reached the Mississippi River. They were probably the warriors who attacked his company after he died, under the leader called "Quiguattam" [*Quigualtanqui*]. The next encounter with them was in 1682 by La Salle, whose treatment was totally different; the French were welcomed into one of their towns. Survivors of a 1729 French attack joined the Catawba, Cherokee, and Creeks (Young and Siebert 2003), and their descendants live in Oklahoma and elsewhere. Officially recognized as the Natchez Nation, they consider themselves direct descendants of the Mound Builders (Fields 2003). The Natchez at contact lived in southwestern Mississippi and east-central Louisiana (Swanton 1946, Grosvenor et al. 1972). Fields (2003), the current *Cunv Uvse* (Great Sun) of the Nation, records towns in Oklahoma, Georgia, and South Carolina.

**POWHATAN** (“falls in a current of water”; Algonquian language family) The Powhatan were in the tidewater of Virginia on both sides of Chesapeake Bay in 1607 when Virginia was established. The fabled Pocahontas, a real individual, was the daughter of the ruling leader at the time of European contact. Although the British called this leader Powhatan, his name was “Wahunsonacock.” Several of the allied group names live on in localities, including Chickahominy, Potomac, Powhatan, and Rappahannock.

**SEMINOLE** (either “people of a distant fire” or “wild ones,” which is about the same; Muskogean language family) Simpson (1956) thought “Seminole” was derived from Creek *isti semoli*, people of a distant fire. The Seminole tribe of Florida publishes that their name came from Spanish *cimarrón*, wild or untamed. Fairbanks (1978) found historical data that the name “Seminole” came into existence about the 1760s, when they began being called “Seminoles” or “Siminoles” in English and *Cimarrones* in Spanish. The name was applied by the Spanish because these new immigrants in Florida “had left their settled towns and had established themselves in wild, vacant lands.” The Muskogean tongues have no sound corresponding to the “r” in English or Spanish, and they first pronounced the word “Simalones” or “Simanoles.” At first it seems incongruous that the Seminoles, who rarely spoke any Spanish, would have their name derived from a Hispanic word. However, there are at least two possible reasons for this, and for the presence in their languages of other loan-words from Spanish. People who became the Seminoles mingled with members of the Yemassee (*yi musí*, ancient people, Catawba) and the Glades people. Both the Yemassee and the Glades people had been under Spanish influence for a long time and knew some of the language (cf. Simmons [1822] 1973, Swanton 1946).

**TIMUCUA** (from *atimoqua*, lord or ruler; Timucuan language family) Timucua was the original name of a group later called *Utina* (powerful). Ponce de León first encountered the Fresh Water Timucua in 1513. Several others visited the area between then and 1528 when the Narváez expedition passed through their territory. However, it was the de Soto expedition in 1539 that gave the clearest description of the Western Timucua, and the French groups under Jean Ribault in 1562 and Ludonnière and Le Moyne in 1564–1565 that described the Eastern Timucua. At the time of contact, the Timucua dominated the Florida peninsula north of Lake Okeechobee. They were extinct by 1740, but Swanton (1946) thought that the Seminole town of *Etaine* was the same as *Utina* and that it might contain remnants of the people.

**YUCHI** [*Euchee*, *Uchi*] (“far away people” in their language, or perhaps a form of the Hitichiti word *ochesee*, “people of another language”; an isolated language) Their language has been considered Muskogean (Speck 1909, Swanton 1946) or Siouan (Billard 1974), but most agree they speak a unique language (Martin and Mauldin 2000, Jackson 2003). When de Soto passed near their region, the Yuchi were living west of the Cherokee in the hilly country of eastern Tennessee. Later there were scattered groups of Yuchi, one on the western parts of the Appalachians or the plateau lands beyond, and others throughout the southeast from Alabama to Georgia. The village in Alabama was visited first in 1701. For more information, see Swanton (1953). Some of the Yuchi went to Oklahoma and settled on the western part of the Creek territory. Others went to Florida and joined the Seminoles (Speck 1909, Jackson 2003).

### Caribbean People

The Caribbean was populated by two basic groups, the Arawakan and Cariban tribes. The distinction between these two was not always clear, as there was intermarriage between them in the Lesser Antilles.

**Taino** The northern Caribbean, from the Bahamas and Cuba to Puerto Rico, was populated by Arawakan people typically called the Taino, although that designation oversimplifies reality (Sauer 1969). Columbus provided the first glimpses of these agricultural people when he arrived in the Bahamas and later in Cuba, Hispaniola, and Jamaica (Jane and Skelton 1960). The number of Taino words incorporated into Spanish is remarkable (Coll y Toste 1972), and many of the plant names used as far away as western Mexico and Peru are Taino words. Some familiar Taino words in English are Cuba, maguey, maize, and tobacco.

**Carib** Although perhaps the only remnant of Cariban culture remaining in the Antilles is on Dominica, the Carib have relatives in South America (Hodge and Taylor 1957, Taylor 1977). One of the unique aspects of the Antillean Caribs is that they stole their women from Arawakan villages. Men ostensibly continued speaking their language, while the women spoke their native Arawakan tongues. In reality, Taylor (1977) indicated that the hybrid languages were more Arawakan than Cariban.

Columbus's understanding of the Taino also added the words "Carib" (akin to *Galibi*, literally "strong men") and "cannibal" (from *caniba*, Arawakan) to English. For example, on 23 November 1492, his journal contains an entry that the Taino whom they captured in Cuba said that to the east was an island Columbus misunderstood as being called *Bohio* (house, Taino). That island we now know as Hispaniola, and the captive indicated that "this land was very extensive and that in it were people who had one eye in the forehead, and others whom they called 'Cannibals.' Of the last, they showed great fear, and when they saw that this course was being taken, they were speechless."

### Mexico's People

At the time of contact with Europe, Mexico was home to hundreds of languages. Although plant names are given from several of these languages, the majority are taken from three dominant groups, the Aztecs, the Maya, and the Zapotec.

**Aztecs** Focused around the area that is now Mexico City were the people who called themselves *Mexicas* or *Aztecas*. Their language was Náhuatl, and an unusually complete vocabulary was compiled by Spanish priests (Siméon [1885] 1981). Much of the Creole Spanish spoken in central Mexico retains words from their language. Farther from that region, other languages may prevail, but there is still a heavy influence from former Aztec domination.

**Maya** In the Yucatán region of Mexico and south into much of Central America, the dominant language is Mayan, with multiple dialects (actually considered languages by many) such as Huastec. Few publications on plants have translated words from Mayan, and outstanding among these is the work by Alcorn (1984).

**Zapotec** A third linguistic group in southern Mexico of considerable historic importance is the Zapotec. Reko (1945) has given an exemplary account of their knowledge and beliefs regarding plants.

The trade systems of all three of these groups are staggering. According to Hernando Cortés the central square of *Tenochtitlan* (*Tenoch*, chief of the Aztecs who founded the city in A.D. 1325, *tlan*, near) was surpassed by the one at *Tlateloloc* (Soustelle 1962). Cortés wrote that in *Tlateloloc* (*tlatelli*, height or elevation, *tlatia*, burned or hidden), there were more than 60,000 people trading every day and that “there are all kinds of merchandise from all the provinces, whether it is provisions, victuals or jewels of gold and silver.”

The Aztecs in the Valley of Mexico kept regular contact with the Gulf and Pacific coasts. Their leaders, the Moctezumas, are said to have dined on fresh fish taken in the mornings on seacoasts. Given the lists of items in markets by Bernal Díaz del Castillo between 1517 and 1521 (Díaz 1956) and those recorded for the Moctezumas’ meals by Fray Bernardino de Sahagún in the 1500s, that is believable (Soustelle 1962).

There is even evidence that people in Mexico City traded far to the north. Comparisons between the images of *Kokopelli* (maybe from *koko*, god, *PELLI*, a humpbacked robber fly, Hopi) in the Pueblo regions of New Mexico and Arizona and the *Xochipilli* (*xochitl*, flower, *pilli*, lord) of Mexico City suggest that there were traders moving between those areas also (Schultes and Hofmann 1979, Young 1990, Bob Bye, personal communication, 1993). Even the names *Kokopelli* and *Xochipilli* may be cognates. Some think that these names and images represent the actual traders moving between regions.

By the time the La Venta center of Olmec culture on coastal Tabasco, Mexico, was flourishing from 800 to 400 B.C., they engaged in trade with the highland Maya area (Schlesinger 2002). These north-south routes brought them, among other items, jadeite, obsidian, and surely also plants. The Maya also had trade routes connecting them with *Teotihuacan* (*teotl*, god, *iuu*, sent, *can*, place) in the central valley of Mexico. Hay et al. (1940) had already discovered trade routes that connected the region of Guatemala City with San José in Costa Rica. Among the many items traded by the Maya from the Pacific coast were chocolate seeds (*Theobroma cacao*). Thus, at a minimum, the Maya were trading from Mexico City to San José, Costa Rica, and with both the Gulf and Pacific coasts.

In his second voyage of 1526–1527, Francisco Pizarro’s pilot Bartolomé Ruiz was the first to report rafts off the coast of Panama traveling on the open sea like the Spanish ships (Prescott 1892). Those rafts were actually Peruvian, and belonged to traders from that Incan empire. To the Spanish, these rafts were *almadías* or *balsas*, while the Incas called them *huampu*, and gave names to at least 13 different kinds. Inhabitants of Darien, Panama, called them *pucro*. Urteaga (1978) has given one of the most detailed of recent discussions regarding transport of trading cargo aboard balsas.

There is historical and archaeological evidence that Peruvians used these *balsas* to trade with the Zapotecs in western Mexico (Eubanks 1999). Similarly, Madsen et al. (2001) were convinced that people from Puná Island in Ecuador were also involved in that trade system.

### Northern South American People

Along coastal Venezuela and in the Guianas, there was a mosaic of Arawakan- and Cariban-speaking people. Because these areas were among the first places visited by the

Spanish, considerable plant information was exchanged. Sometimes it is possible to find distinctions between the continental Arawakan or Cariban names of plants and those used on the islands. Frenchman Jean Baptiste Christophore Fuseé Aublet (1720–1778) visited the Cayenne region in the 1770s and gave many indigenous names, including working them into scientific names (Plotkin et al. 1991). That usage scandalized some Europeans like Linnaeus who thought scientific names should be based on Greek and Latin, but Aublet (1775) produced an important ethnobotanical commentary.

Surprisingly, there are even a few Tupí names from Brazil in plant names used in the Caribbean. Tupí and its relative language Guaraní were dominant along the eastern coast of South America at the time of European contact, and countless Tupí words have become elements of Creole Portuguese (Sampaio 1970, Ferreira 1978). Some of those words have even moved into English, e.g., genip, ipecac, or ipecacuanha.

### *Old World Newcomers*

#### **European Settlers**

The early European settlers along the eastern coast of North America included the Dutch, English, French, German, Spanish, and Swedish. Among others who visited the region, Kalm ([1753–1761] 1972) noted the Dutch, German, and Swedish people in the New Jersey region and eastern Canada. It was, however, the English, French, and Spanish who are best known in the regions farther south. The southern Europeans brought with them Gaelic views merged with those of later people. All the Europeans were heavily influenced by Greek and Roman thinking, especially when it came to plants (Arber 1986, Baumann 1993, Meyer et al. 1999).

The first Europeans to interact with indigenous Floridians were the Spanish, officially beginning in 1513. However, as Williams ([1837] 1962) and others have noted, the region may have first been seen by Sebastian Cabot in 1497 when, under the flag of England, he sailed along the eastern shore. Beaufort, South Carolina, claims to be the second landing site of the Spanish in the New World, where Captain Pedro de Salazar landed in 1514 (Anonymous 2003). One of the first interactions between the Spanish and people in what is now the Carolinas occurred when a slaving raid was sent from Hispaniola in 1518. That excursion set the pattern for Spanish attempts to obtain workers for their mines (Williams [1837] 1962). Lucas Vázquez de Allyón made two exploratory voyages to the Atlantic Coast in 1520 and 1523 (Milanich and Milbrath 1989). On the first reconnaissance, Allyón found a cluster of islands off the coast of what is now South Carolina and named them *Santa Elena* (Stormer 1993). Then, in 1526, Allyón brought settlers to *La Florida* and tried to establish a colony at *San Miguel de Gualdape*, probably on the Georgia coast. They lasted only 3 months.

Better known is that there were French colonies on the *Río de San Juan* (St. Johns River) and at *Santa Elena* in South Carolina (Barrientos [1567] 1965, Bloodworth and Morris 1978). Jean Ribault, leader of the Huguenots, and his men built Charlesfort in 1562 on present-day Parris Island off Beaufort, South Carolina. In Florida, they built Fort Caroline in 1564. This intrusion of Protestants into the Spanish Catholic realm was not tolerated, and they were quickly eliminated (see *Sassafras* for more details). In spite of

their short tenure in Florida, the drawings made by their artist Jacques Le Moyne provide much of what is known from the time.

Pedro Menéndez reestablished Spanish dominance at *Santa Elena* in 1566, after expulsion of the French in 1564. The name *Santa Elena* came to represent an area on the southeastern coast of North America including most of present-day South Carolina, North Carolina, and parts of Georgia. Later it was the name of the first permanent settlement by the Spanish on present-day Parris Island, South Carolina, and the first capital of Spanish holdings in North America. Nicholas Monardes (Frampton [1577] 1925) gave a first glimpse of Florida and medicinal plants in 1569.

The Spanish capital was moved to St. Augustine in 1565 (Bloodworth and Morris 1978). The full name of this settlement originally was *San Agustín de las Floridas, el siempre fiel Ciudad de San Agustín* (Saint Augustine of the Floridas, the ever faithful city of St. Augustine). Saint Augustine remained the Florida “capital” until Spain ceded the lands to the British in the 1763. Nearby was *San Mateo*, a new name given to Fort Caroline by Menéndez when he captured it on Saint Matthew’s Day.

Although not successful in Florida, the French were able to settle in what is now eastern Canada, the Mississippi River valley, and Louisiana. There they interacted with indigenous people and even engaged them in raids against other tribes and settlers from other countries. For example, when Henri de Tonti was among the Illinois in 1682, he told about his instigation of intertribal conflict. He wrote: “The savages there [Illinois] are active and brave...in war, when they think nothing of seeking their enemies at a distance of 500 or 600 leagues from their own country. This constantly occurs in the country of the Iroquois whom, at my instigation, they continually harrass” (Tonti in Borland 1965).

By the time Speck (1941) worked with the Houma in Louisiana, they had lost their language and spoke only Creole French. Swanton (1946) made repeated reference to indigenous southeastern people being driven from English-dominated regions to French-held Louisiana.

The early British did not try to compete with the Spanish in Florida, but settled farther north up the coast. Their most famous early attempts at settlements include Roanoke Island in 1584 (see Harriot [1590] 1972, Hulton 1972), Jamestown, Virginia in 1607, the Plymouth Colony, Massachusetts in 1620, and Charleston (as Charles Towne), South Carolina in 1670. The Roanoke colony was a failure, but there are still people who claim to be descended from mixing of those colonists with indigenous tribes (see [www.lumbeetribe.com](http://www.lumbeetribe.com)). Simmons ([1822] 1973), Vignoles ([1823] 1977), and Williams ([1837] 1962) all provided insight into the early years of Florida becoming a territory.

Europeans had completely different views on the human’s place in the world than the indigenous people. The philosophy of these light-skinned races from the Old World was Judeo-Christian. Essentially all of these newcomers believed the biblical comment that they should “conquer the land.” Kalm ([1753–1761] 1972) was one of many who complained about their disregard for the future by devastating their resources.

### Africans

Probably the first Africans to be brought to the southeastern region were left in 1526 when the Spanish abandoned the abortive colony at *San Miguel de Gualdape* (Milanich

and Milbrath 1989). These Africans were members of the *Mende* [*Minde*] tribe from what is now called Sierra Leone in West Africa. Allyón had brought these people specifically because they were experienced in growing rice (Stormer 1993).

Subsequently, other African slaves were brought to the area because of their knowledge of rice (Carney 2001). Among these people were the *Mende*, *Kisi*, *Malinke*, and *Bantu* (Stormer 1993). Because they could not speak the same language, the people created a new language and culture, melded from Elizabethan English and their own individual dialects and languages. Although outsiders call them *Gullah*, these people formerly called themselves the *Geech* or *GeeChee*. According to the *Encyclopedia Britannica* (2003), both *Gullah* and *Geechee* are West African tribal names, although one source says *Gullah* was derived from *Angola*. Their descendants still occupy coastal regions in Florida to South Carolina (see [www.coax.net/people/lwf/gg\\_coal.htm](http://www.coax.net/people/lwf/gg_coal.htm)).

Some of the Africans brought to the New World would not tolerate being slaves and escaped. As the ancestors of the Seminoles were forced farther south, some of these blacks joined them and fought by their sides during their wars with the British and then the Americans. Fairbanks (1978) recognized two main patterns of interactions between blacks and Seminoles.

Williams ([1837] 1962) said Seminoles held slaves, but Fairbanks (1978) called these individual client relationships. The blacks were advisors, particularly in matters involving whites. Both cite the same example of *Wealusta* (Black Creek) and a black individual named Abraham, who served as interpreter when the Seminoles sent a deputation to Washington, D.C. in the early 1800s.

The second pattern occurred where the Africans maintained farming villages beside those of the Seminoles. This arrangement hastened acculturation of the Seminoles but rarely had an impact on their gene pool; some say never, but Sturtevant (1955) said Billy Bowlegs was half black. These Africans were allies of the Seminoles and fought beside them. Williams ([1837] 1962), for example, recorded a group of about 50 blacks who fought with the Seminoles against Major Dade at the battle at the Big Withlacoochee (we, water, *tako*, big, *chee*, little, or “little river”), later known as the Dade Massacre (Simpson 1956, Bloodworth and Morris 1978).

The attitude of the Seminoles toward the Africans was markedly distinct from the general feeling among the Creeks and other Muskogean people (Fairbanks 1978). These tribes sometimes held blacks in slavery. On other occasions, as in the battles at Pensacola in 1816, the Choctaw were enlisted to help the English capture and squelch a “Negro” fort (Williams [1837] 1962).

Grimé (1976) attributed the African use of American plants to independent discovery. However, comparison with use by indigenous people suggests that they learned much, if not all, of their uses from them. On the other hand, Africans surely taught the indigenous tribes uses of Old World plants.

Africans brought with them a worldview more like indigenous people than the Europeans (Iwu 1993). They believe that everything, living or inanimate, has a “life force that can only be properly harnessed and utilized by the knowledgeable and the initiated.” This has incorrectly been called animism. The spirits are not worshiped, but instead consulted to achieve a goal. Daily life is considered inseparable from religion.

## *The Ethnoflora*

### **First European Impressions**

Although they were typically sparse, many of the first records of the New World contained comments on plants and indigenous uses. Often, these reports of the New World in Europe sounded like modern advertising propaganda. Columbus started it all.

Columbus wrote of his first landing in the *Lucayos* [Bahamas] on 11 October: “When they had landed, they saw very green trees and much water and fruit of various kinds” (Jane and Skelton 1960). He was impressed with the trees, and on 13 October he wrote that the people who lived there “came to the ship in boats, which are made of a tree-trunk like a long boat and all of one piece. They are very wonderfully carved ...and large, so that some forty or forty-five men came.” The Taino called these boats *canoas*, which came into English as “canoes.”

On 16 October Columbus wrote, “I saw many trees very unlike ours, and many of them had many branches of different kinds, and all coming from one root; one branch is of one kind and one of another, and they are so unlike each other that it is the greatest wonder in the world. How great is the difference between one and another! For example: one branch has leaves like those of a cane and another leaves like those of a mastic tree.” That was probably the first European literary record of strangler figs (*Ficus*) growing on palms.

A month later, on the island of Cuba, Columbus was at a loss to explain what he had seen. His scribes wrote for him: “He praises all this very highly to the Sovereigns, and declares that he felt inestimable pleasure and delight at seeing it, and especially the pines, because here could be built as many ships as might be wished, bringing out the materials, except timber and pitch, of which there would be an abundance here. And he affirms that he has not praised it to the hundredth part of that which might be said, and that it pleased Our Lord always to show him something better, and that continually in his discoveries up to then he had gone from good to better, as well in the matter of the land and trees, herbs, fruit and flowers, as in that of the people, and always in a different manner, and as this was the case in one place, so it was in the next.”

After being in Florida in 1562, French promoter of the Protestant Huguenot colony Jean Ribaut (ca. 1520–1565), wrote to his commander Admiral Gaspard de Châtillon, comte de Coligny (1519–1572), about finding “merueylous commodities and treasures of the country” in an English version that was published in London in 1563. Farther along he wrote: “we sailed and veewed the coast all along with an unspeakable pleasure of thodiferous smell and bewtye of the same.... The Indians received us verry gentelly with great humanytie, putting us of these frutes, even in our boates, as mulberries, respices and such other frutes as they found redely by the waye. We enterd and vewed the cuntry therabowte, which is the fairest, frutefullest and pleasantest of all the world, habounding in honey, veneson, wildfoule, forrestes, woodes of all sorts, the hiest, greatest and fairist vynes in all the wourld with grapes accordingly. There growith also many walnut-trees, hazeltrees and small cherytrees very fine and great, and generally we have sene there of the same symples and herbes that we have in Fraunce and of like goodness savour and tast.”

That Ribaut was not above exaggeration is shown by his mention of honey. Bees (*Apis mellifera*) were not yet introduced into North America, and there could have been no honey there yet. Moreover, it is likely that he was describing the region in what is now South Carolina because hazel trees (*Corylus*) do not grow in Florida.

Spanish biographer Barrientos ([1567] 1965) was similarly exuberant in writing about the exploits of Pedro Menéndez de Aviles. The *Adelantado* could not have known of many of these items from personal experience, so Barrientos must have used documents from the de Soto or some other expedition in producing his report. Kerrigan has rendered the archaic Spanish into modern English easier to understand, but he has retained the enthusiasm of the original. Barrientos wrote: "Although the land is flat, far inland there are some mountain ranges. Everywhere are extensive woods, undergrowth and trees. Some of the trees are marvelously tall; among them are walnut [*nogales*], laurel [*laureles*], liquidambar [*liquidanbares*], savine [*savinas*, junipers], wild olive [*acebuches*], live oak [*encinas*], oak [*robles*], pine [*pinos*], and plum [*ciruelos*]. There are also wild vineyards [*parras silvestres*], cereals [*servales*, but now *cereales*], and palmettos [*palmitos*] like those of Andalucía. Mulberry trees [*morales*], suitable for silk-making, are plentiful. Large lakes are numerous, and many of them are deep. Maize fields [*mayzales*] are on every hand." A bit farther along he continued that he found among the "produce of the earth," beans [*frisoles*], maize [*maize*], squash [*calabazas*], walnuts [*nueces*], chestnuts [*castañas*], and filberts [*avellanas*].

Of the "countless grapes," Barrientos wrote that "muscatel grapes [*ubas moscateles*] abound, and they are as good as the Spanish variety. Extensive oak groves yield an abundance of acorns [*vellotas*]." Showing that he knew of prior expedition reports he wrote that "enclosed gardens are to be found in Coza," a Muskogean village in what is now Georgia. At *Cofitachiqui*, another Muskogee village in Georgia, "mulberry groves are so thick that it is necessary to cut them down in order to make plantings. From the mulberries the Indians make raisins [*pasas*], which are good to eat."

### Indigenous and Other Utilization

Little information exists about plant use by the first Florida people. Examination of the extant documents reveals that we have about 3% of the flora recorded as used by Glades and Timucuan people (Austin 1980, 1997). Elsewhere in North America, we know that people used ~20% of flora (Yarnell 1964, Austin and McJunkin 1978). The only comparable American figure for a nearby area is Mexico, where Bye (1993) estimated a 23% ethnoflora (5,000/30,000 species). However, only 3352 species (~11%) have documented use in Mexico. A report by Manandkhar (2002) that about 20% of the flora of Nepal is used by people is also tantalizing.

We have about half the number of records (10%) for native plant usage by Mikasuki and Creek speakers of southern Florida (Sturtevant 1955, Snow and Stans 2001) as for other American groups (Bushnell 1909, Swanton 1928a, Hamel and Chiltoskey 1975, Bye 1993). Some of that knowledge has been preserved in modern traditions remaining among those people, and in the literature (Swanton 1928a, Sturtevant 1955, Howard 1984, Snow and Stans 2001). However, no previous study has compared the potential biodiversity with the species that have documented uses.

It is my experience that people are inquisitive and inventive with plants; comparison of the literature suggests the same. People in the New World have experimented with introduced plants to the point that they have incorporated hundreds of alien species into their ethnofloras (see Morton 1981, Arvigo and Balick 1993, Moerman 1998, Bennett and Prance 2000). The Old World peach (*Prunus persica*) is one example where indigenous Americans quickly adopted and spread a new species. As with the swine and opossums (see *Sagittaria*), old words were substituted for these new fruit trees. The Powhatan called plums *poskam*. Later, cognates in related Algonquian languages were applied to the peach, as *poŋkama* in Shawnee, and *pokkitons* in Ojibwa. A similar substitution took place in the Muskogean languages. Muskogee for the *Prunus americana* is *pvkánvhe* (plum tree). The Creeks and Seminoles call peaches *pvkanv*, while their relatives say *tohā:nî* (Mikasuki), *takkolá* (Chickasaw, Choctaw, Koasati), and *takkola* (Alabama). The peach was so widespread among indigenous people that biologists thought for decades it might be native to the New World.

Humans not only experiment with plants to see what impacts they have on people, but they exchange information with their neighbors. That does not mean that each person within even the same village or town will use a single species the same way. Instead, they often have different applications for the same species, demonstrating personal bias and experiences (cf. Snow and Stans 2001). Therefore, this compilation is based on a simple premise: *If people in other places use the plants, then people in Florida used them.*

Archaeological and historical records make it clear that the people in the southeastern United States were fervent travelers and traders. Mississippian Complex people in the period that preceded historical contact had a trade network that extended from the Gulf of Mexico to the Great Lakes, and from the Atlantic Coast to the Rocky Mountains (Brown et al. 1990, Booker et al. 1992). Drechsel (1997) makes the convincing argument that the Mississippian Complex peoples, with their many and varied unintelligible languages, developed the Mobilian Jargon, at least in part, so that they could carry out trade across the region. He wrote that the jargon was “the language of voyages, in which Southeastern and other Indians engaged enthusiastically and over great distances.” There are documented records of native people traveling by both land trails and natural waterways. These travelers often went for several hundred miles and occasionally even farther than a thousand miles (Drechsel 1997). The use of the Mobilian Jargon in historic times reached at least to, but not including, the Cherokee in Tennessee and the Catabwa of the Carolinas, north to the Osage or Oto of the Missouri River, and west through about the eastern third of Texas to the Caddo and Natchitoches. The language extended beyond the Muskogean region and incorporated a few words from their Algonquian neighbors on their north (cf. pecan in *Carya*, persimmon in *Diospyros*, and *sagamité* or hominy within *Zed*).

Glades people and Timucuan had ample opportunity to exchange information with their neighbors. We have historical records that Glades people interacted with the pre-European people in Cuba (Fontaneda [1575] 1944), with the Spanish once they arrived on that island and on mainland Florida, and with the Timucua and other people living to their north in the peninsula (Fontaneda [1575] 1944, Barcia 1951, Hann 1991). Therefore, comparison with nearby areas (Mexico, North, Central, and South America, the Bahamas, the Caribbean) should provide a Florida Ethnoflora. That comparison is made in Table 1,

which lists all of the Florida native plants that are known to have been used by people surrounding Florida.

Comparative information has been taken from Alcorn (1984), Arvigo and Balick (1993), Ayensu (1981), Bartram ([1791] 1958), Densmore (1928), Fernald et al. (1958), Foster and Duke (1990), Gilmore (1977), Honychurch (1987), Krochmal and Krochmal (1973), Liogier (1974), Little and Wadsworth (1964), Morton (1974, 1981), Roig (1945), Small (1933), Standley (1924), Standley and Record (1936), Taylor (1940), and Balick et al. (2000). Other primary references containing pertinent information are Arnason et al. (1980), Coe and Anderson (1996), Lewis (1992), Millsbaugh (1892), Schetky (1964), and Vogel (1970). Numerous additional publications are cited within the text dealing with individual species.

The species accounts treat 813 of the 886 Florida species with documented uses. Summary information on the remaining species is given in Table 2. Elsewhere, Moerman (1998) has given the most complete synopsis available. However, even that large compilation is inadequate for southern Florida, as he himself noted (Moerman 1991). An attempt has been made to include all kinds of uses, ranging from utilitarian (wood, posts, dyes, fibers for ropes, etc.) to food, medicinal, and in religion.

Wunderlin (1998) calculated that Florida has 2654 native species. Although that figure might be debated, it represents a working number for comparison. The 888 species (Table 1) in the Florida Ethnoflora represent 33.5% of the native, pre-Columbian flora. That figure is considerably above the percentage documented as used by indigenous Florida people (~10%) and by people in other areas (20%) as recorded by Yarnell (1964), Griffin (1967), Austin and McJunkin (1978), Bye (1993), and Manandkhar (2002). My compilation suggests that Florida's lost ethnoflora consists of at least 13.5% of the native plants, or the difference between the 20% ethnoflora in other areas and the one reconstructed for Florida (33.5%).

However, data in Table 3 and Table 4 indicate that even those figures probably are too low. If, indeed, those species in these tables were also used, then the Florida ethnoflora would be 888+[Table 3=] 59+ [Table 4=] 36=983 species. That information might indicate that 37% of the flora was used by indigenous people.

I am convinced that even 37% is too low. There are many trees (especially genera like *Carya* and *Quercus*) that provide useful wood and fruits that are not accounted for in this discussion. The more I study indigenous attitudes, languages, and my own cultural background, the more I am convinced that we have greatly underestimated the number of plants used by our ancestors. I suspect that indigenous people used 100% of the woody species, and perhaps more than 50% of the other life-forms. Recent discussions with Brad Bennett suggest that he may be gathering data on people in Panama to support that view. Future students of the ethnofloras of the United States and elsewhere should be able test my hypothesis.

**TABLE 1** *Florida's Ethnoflora*

Scientific Name	Comments	Family
<i>Abutilon permolle</i> (Willdenow) Sweet		Malvaceae
<i>Acacia angustissima</i> (Miller) Kuntze		Fabaceae

*Note:* Not in Moerman (1998) =422. Percent of Florida ethnoflora added =422/888 =47.5%. Abbreviations: Glades (G), Timucua (T), and pollen from coprolites at Fort Center (Gp). Family names have been brought in line with Wunderlin and Hansen (2003).

\*Discussed and illustrated under *Eugenia*.

TABLE 2 *Other Species Used*

Scientific Name	Common Names	Uses	Group(s) or Area Using	Chemistry
<i>Acalypha rhomboidea</i>	copperleaf	Reputedly medical (Hocking 1997); several others are used in Middle America (Morton 1981)	Eastern USA	
<i>Acanthocereus tetragonus</i>	dildoe cactus, triangle-cactus	Fruits edible (Morton 1968c)	Florida; Caribbean	
<i>Amphitecna latifolia</i>	black calabash (Florida, English Antilles), <i>maigüira</i> ( <i>güira</i> , the Taino name for <i>Crescentia</i> , Cuba), <i>güira de olor</i> ( <i>de olor</i> , fragrant, Cuba), <i>higüero</i> [ <i>jigüero</i> ] <i>galion</i> ( <i>higüero</i> , calabash, <i>galion</i> , resembling a Rubiaceae used to cure leather, Dominican Republic), <i>güira cimarrona</i> (wild calabash, Dominican Republic), <i>higüerillo</i> [ <i>cimarrona</i> ] ([wild] calabash, Puerto Rico), <i>calebasier vénéneux</i> (poisonous calabash, French Antilles), <i>calabasse zombi</i> (zombi calabash, Guadeloupe, Martinique)	Wood is used for yokes and plows (Liogier 1974); fruit has the same properties as the <i>higüero</i> ( <i>Crescentia cujete</i> ) and is used as an aperitive and to treat chest problems, sores, headache, dysentery, and other problems (Roig 1945, Liogier 1974, Morton 1981, Austin 1992, 1995)	Florida; Caribbean	
<i>Amsonia tabernaemontana</i>	eastern bluestar	Central nervous system stimulant (Hocking 1997)	USA	Indole alkaloids
<i>Axonopus compressus</i>	tropical [broad-leaf] carpet-grass, <i>pahí hiná:ba</i> ( <i>pahí</i> , grass, <i>hiná:ba</i> , hard, Koasati)	Named and perhaps used (Kimball 1994); flowers chewed and used as face poultice in Samoa (Hocking 1997)	Louisiana	
<i>Azolla caroliniana</i>	mosquito fern, mosquito plant, <i>ifa kika</i> (Arawak, Suriname)	Believed to drive mosquitoes away (Hocking 1997)	Tropical America	
<i>Bejaria racemosa</i>	tarflower	Shortly after I arrived in Florida I was told	Florida	

		that the plant was used as fly-paper before screens were available; no published source has been found to verify that		
<i>Brasenia schreberi</i>	watershield	Meskwaki used the plant to treat stomach ailments and during menses (King 1984); recent use includes treatment of dysentery and tuberculosis (Hocking 1997)	Meskwaki	
<i>Brickellia eupatorioides</i>	prairie false boneset, false boneset	Bitter tonic, diaphoretic; old injury, coughs (Hocking 1997, Moerman 1998)	Florida; Navajo	
<i>Buchnera americana</i>	blue-hearts	Seminoles used this in 1919 as an emetic for headache, dizziness (von Reis and Lipp 1982)	Florida; Caribbean	
<i>Bulbostylis capillaris</i>	<i>partillo chico</i> (little ?)	Mouthwash for toothache (von Reis and Lipp 1982)	Paraguay	
<i>Cenchrus echinatus</i>	bur-grass, West Indian bur-grass	Fruits eaten and used to make alcoholic beverage (Hocking 1997)	Tropical America, southern USA	
<i>Cenchrus incertus</i> (= <i>C. pauciflorus</i> , <i>C. spinifex</i> )	coast sandbur, <i>oktyfonv</i> (Muskogee), <i>roseta</i> (rosette, New Mexico), <i>sacate cochonillo</i> (little pig grass, San Luis Potosí)	A decoction of the plant used in making blue cornmeal mush, and also given to nursing mothers to increase lactation (Curtin 1947, von Reis and Lipp 1982)	Mexico, New Mexico	
<i>Ceratiola ericoides</i>	rosemary	Domestic medicine (Hocking 1997)	Florida	
<i>Ceratophyllum demersum</i>	coontail, horn wort	To treat biliousness, scorpion stings (Hocking 1997)	Southeastern USA	
<i>Chaerophyllum procumbens</i>	<i>cerofoglio selvatico</i> (wild elegant leaf, Italian), <i>cerfeuil savage</i> (wild chervil, French) chervil (from	Campbell (1951) reported that the Chickasaws considered <i>C. procumbens</i> poisonous and used it as an emetic; subsequently the	Southeastern USA	

	Latin <i>chaeraphylla</i> , through Old English <i>caerfille</i> ; akin to Old High German kervala, and Middle Dutch kervele), spreading chervil	specimens in the Gideon Linneum (1793–1847) collection at Texas have now been determined as <i>Osmorhiza longistyla</i> (Torrey) de Candolle, and the report was incorrect (Joanne Birch, personal communication, June 2003)		
<i>Coreopsis major</i>	starry coreopsis	Leaves used to dye eggs (Hocking 1997)	Southern USA	
<i>Coreopsis tripteris</i>	tall tickseed	Decoction of stems for pain and internal bleeding (Moerman 1998)	Meskwaki	
<i>Encyclia tampensis</i>	butterfly orchid, <i>tha-ta</i> or <i>ta-ta-he</i> (minnow plant, Mikasuki), <i>suhatkochi inhombitat</i> (squirrel's food, Creek)	Seminole children carve pseudobulbs into animals (Bennett 1997)	Florida Seminoles	
<i>Eriogonum tomentosum</i>	deer tongue, wild buckwheat	Leaves put in pillow to relieve asthma (Murphee 1965)	Florida Panhandle	
<i>Eustachys glauca</i>	star grass, saltmarsh finger grass	Tea made from the roots are laxative (Murphee 1965)	Florida Panhandle	
<i>Fimbristylis spadicea</i>	<i>cabezón</i> (Venezuela), <i>esparrago</i> (Veracruz?), <i>esparto</i> , <i>kuna-biaya</i> (Guajiro?)	In northwestern Venezuela around Río Negro, Perija, this sedge used to heal umbilical cord in infants; paper has been made from the stems in Veracruz (Morton 1981)	Venezuela	
<i>Fleischmannia incarnata</i> (= <i>Eupatorium incarnatum</i> )	<i>mata</i> (herb, Mexico), pink boneset, pink eupatorium,	The drying plant is vanilla-scented (Fernald 1950, Steyermark 1963); formerly added to pipe smoking tobacco in Mexico; one of the bioactive compounds in the herbs is coumarin (Hocking 1997); in Belize, <i>F. pratensis</i> is listed as a medicinal herb (Balick et al. 2000)	Missouri; Mexico, Belize	Coumarin
<i>Froelichia floridana</i>	cotton weed [cottonweed], [field, plains] snake cotton (Florida, Texas), wild cotton (Alabama)	It was apparently a personal observation that Hocking (1997) recorded the plant being used in domestic medicine in Redhav Florida	Florida	

		in 1940; unfortunately, he gave no details	
<i>Gratiola aurea</i>	hedge hyssop	Roots as drastic and anthelmintic and for gout (Hocking 1997)	Southeastern USA
<i>Harrisia aboriginum</i>	prickly apple-cactus	Fruits edible (Morton 1968c)	Florida
<i>Harrisia fragrans</i>	Caribbean apple-cactus	Fruits edible (Morton 1968c)	Florida
<i>Harrisia simpsonii</i>	Simpson's apple-cactus	Fruits edible (Morton 1968c)	Florida

Scientific Name	Common Names	Uses	Group(s) or Area Using	Chemistry
<i>Helianthemum corymbosum</i>	rock rose, frostweed, ice plant	Alterative, tonic, to treat wounds, diarrhea, dysentery (Hocking 1997)	Eastern USA	
<i>Hypelete trifoliata</i>	white-ironwood (Bahamas), inkwood (Florida), <i>hueso de costa</i> (coastal bone, Cuba), <i>chandelle marron</i> (wild candle, Haiti)	Judging from the common name, used for ink; the wood used in the Caribbean (Little et al. 1974)	Caribbean	
<i>Ilex decidua</i>	possum-haw, <i>solopí ahissi</i> ( <i>solopí</i> , ghost, <i>ahissi</i> , medicine, Koasati)	Named and perhaps used (Folsom-Dickerson 1965)	Louisiana	
<i>Ilex opaca</i>	American holly, <i>ittohissi halokpá</i> [ <i>thishalokpá</i> ] ( <i>ittó</i> , tree, <i>hissi</i> , leaf, <i>halokpá</i> , sharp, Koasati); <i>iti hishi halupa</i> ( <i>iti</i> , tree, <i>hishi</i> , leaf, <i>halupa</i> , sharp, Choctaw)	Bark boiled in water and infusion rubbed on itching skin by Koasati (Taylor 1940); Alabama, Catawba, and Choctaw used the infusion to wash sore eyes (Taylor 1940); Cherokee chewed berries for upset stomach (Hamel and Chiltoskey 1975); leaves and bark contain neutral bitter principle used as bitter, and to treat fevers in malaria, and rheumatism by Mississinni blacks (Hocking	Louisiana, Mississippi	

1997)				
<i>Ilex verticillata</i>	yaupon	Yanovsky (1936) said the leaves were use to make tea in the northeastern states; Vogel (1970), King (1984), and Moerman (1998) found records of the Iroquois, Ojibwa, and Meskwaki treating diarrhea and sores with the plants	Iowa to Canada	
<i>Illicium floridanum</i>	stink bush (Florida, South Carolina), purple anise, tree anise	Flowers and crushed leaves smell like dead fish; bark aromatic tonic; leaves and fruits toxic (Hocking 1997)	Southeastern USA	
<i>Illicium parviflorum</i>	star anise, yellow anise tree	Bark source of anise oil; roots used like sassafras (Hocking 1997)	Southeastern USA	
<i>Ipomoea macrorrhiza</i>	largeroot morning glory (Florida), <i>liane à minguet</i> (French)	A rare plant in Alabama, Florida, Georgia, Mississippi and the Carolinas (Beaufort and Georgetown Counties SC; Brunswick County, NC); the species is mostly associated with Indian mounds and perhaps that is why Hocking (1997) says “used medicinally”		Probably contains resins in the roots
<i>Itea virginica</i>	sweet-spire, tassel-white, Virginia tea, Virginia willow	A common name alludes to a use as a tea; the Old World <i>I. chinensis</i> is used in a fruit decoction to aid digestion (Hocking 1997)	Southeastern USA	
<i>Jacquemontia curtisii</i>	white jacquemontia	Seminoles rub the whole plant decoction on ailing legs (von Reis and Lipp 1982)	Southern Florida	
<i>Lechea minor</i>	[thyme-leaf] pin weed, <i>bakloski:kivikcī</i> (diarrhea medicine, Mikasuki), <i>narkaya: kitahiliswā</i> (diarrhea medicine, Creek), <i>yehot nuwi'hare</i> (tie-leaf, Catawba)	Used to treat a “Bird Sickness,” diarrhea, and fever (Sturtevant 1955); Catawba used some <i>Lechea</i> to treat sores (Speck 1934)		

<i>Leersia hexandra</i>	<i>herbe rasoir</i> (raser herb, French)	Used in tuberculosis in Senegal (Hocking 1997)	Africa; also	
<i>Linaria canadensis</i>	[wild] toad flax	Used as diuretic, laxative, and ointment on hemorrhoids (Hocking 1997)	Americas? Eastern USA	
<i>Melanthium virginicum</i> (= <i>Veratrum virginicum</i> )	bunchflower, black flower	Decoction of roots toxic; used to treat scabies (Hocking 1997)		
Mosses	<i>tikbá icokhiskó</i> (beard of the fire, Koasati), <i>iithicooski</i> (fire whiskers, Mikasuki)	Seminoles and other people named and used several kinds of mosses; Kimball (1994) only recorded that the Koasati used the moss to hide where a fire had been; however, Seminoles used it to treat “Fire Sickness” or anything involving too much “heat” (Sturtevant 1955, Bennett 1997); Sturtevant (1955) found several genera of mosses called by the single Mikasuki name	Southeastern USA	
<i>Nothoscordum bivalve</i>	crow-poison, false-garlic, <i>hakhintowá</i> ( <i>hakhá</i> , raven, <i>im</i> , its, <i>towá</i> , onion, Koasati)	Maybe given a name simply to make sure people knew it differed from <i>Allium</i>	Louisiana	
<i>Okenia hypogaea</i>	beach peanut (Florida), <i>mata</i> <i>cancer</i> (cancer stopper, Mexico)	Hinton simply wrote on the herbarium label, “uses: medicinal”	Mexico	
<i>Onoclea sensibilis</i>	sensitive fern	Roots eaten by the Iroquois (Yanovsky 1936) and used as medicine by the Ojibwa (King 1984)	Canada	Contains filicin, filmarone, and oleoresin; very poisonous
<i>Onosmodium virginianum</i>	false gromwell, wild Job’s tears, gravel weed	Roots and seeds diuretic and expel kidney stones (Hocking 1997)		(Swerdlow 2000)
<i>Paspalum floridanum</i>	blue grass, Florida paspalum	A tea made with as much grass as can be circled with the forefinger and thumb is	Florida Panhandle	

		the right amount (Murphee 1965)		
<i>Phegopteris</i> (= <i>Thelypteris</i> ) <i>hexagonaptera</i>	broad beech-fern	Reported to have hypotensive activity (Hocking 1997)		Contains no phloroglucides or filici
<i>Pilocereus robinii</i> (= <i>Pilocereus polygonus</i> )	key tree cactus, tree cactus	Fruits edible (Morton 1968c)	Florida	
<i>Planera aquatica</i>	American planetree, planetree, plene, sycamore, water elm [waterelm], water elmaha, <i>ittofoló</i> ( <i>ittó</i> , tree, <i>foló</i> , spoon, Koasati)	Wood used by fishermen as floats (Harrar and Harrar 1946); wood is light, soft, not strong, close-grained, light brown, with a nearly white sapwood (Sargent 1905); apparently, Koasati used the wood for spoons	Eastern USA	
<i>Polymnia uvedalia</i> (= <i>Smallanthus uvedalia</i> )	bearsfoot, yellow leafcup	Used as a tonic and stimulant, in rheumatism, arthritis, gastritis, hepatic enlargement, cervix-uteri hypertrophy (Hocking 1997); <i>Polymnia canadensis</i> used by Houma	Southeastern USA	Root contains resins, tannins, reducing sugars

Scientific Name	Common Names	Uses	Group(s) or Area Using	Chemistry
<i>Ratibida pinnata</i>	cone-flower	Toothache (Hocking 1997); Moerman (1998) reported the Cheyenne, Dakota, Lakota, and Navajo using <i>R. columnifera</i> for medicine	Meskwaki	
<i>Rhynchosia minima</i>	<i>frijolillo</i> (Puerto Rico), least snout bean [snoutbean], <i>mehenibbech</i> ( <i>mehen</i> , short cycle or life span, <i>ib</i> =little bean or white bean, <i>bech</i> , quail, Maya)	In Curaçao people make a leaf decoction for an eyewash to relieve inflammation; a stronger brew is used to treat venereal disease and as an abortifacient; considered diuretic and used for heart troubles (Morton 1981)	Morton (1981) says the species is native to Asia; Wunderlin (1998) says native to Florida	
<i>Rhynchosia</i>	dollar weed	Dianhoretic for kidney		

<i>reniformis</i>		stones (Hocking 1997)		
<i>Rorippa palustris</i>	hispid yellow-cress, marsh [water] cress	Ceremonial eyewash (Moerman 1998); antiscorbutic, tonic, stimulant, diuretic; in salads (Hocking 1997)	Navajo	
<i>Sebastiania fruticosa</i>	gulf sebastiania	Alabama chewed root as a laxative (Hocking 1997, Moerman 1998)	Alabama	
<i>Sesbania drummondii</i>	rattlebox, coffee-bean, rattle bush, senna bean	Seeds as coffee substitute, but toxic (Hocking 1997)	Southeastern USA	Saponins
<i>Sesbania vesicaria</i>	coffee-bean [weed], bagpod, bladderpod	Seeds apparently edible after cooking (Hocking 1997)		Seeds with fatty oils and toxic principles
<i>Sideroxylon lanuginosa</i>	<i>of old intató</i> ( <i>afoló</i> , screech owl, <i>in</i> , its, <i>tató</i> , honey-locust, Koasati); <i>coyyí notá okwo</i> < <i>t</i> > <i>li</i> ( <i>coyyí</i> , pine, <i>notá</i> underside, <i>okwo</i> < <i>t</i> > <i>li</i> , dewberry, Koasati)	Yanovsky (1936) said the fruits were eaten in the southern states	Southeastern USA	
<i>Silene virginica</i>	fire pink	Vermifuge and nervine (Hocking 1997); Foster and Duke (1990) suggest that there may have been confusion between use of <i>Spigelia marilandica</i> and this as both are called “pinks”	Core (1967) found no evidence of the plants being used	Saponins (Hocking 1997)
<i>Solanum carolinense</i>	Carolina nightshade, [Florida] horse-nettle, <i>wasó i</i> < <i>t</i> > <i>laki</i> ( <i>wasó</i> , wolf, <i>im</i> , its, < <i>t</i> > <i>laki</i> , arrow, Koasati)	The Cherokee took an infusion to expel worms, put it on sores and poison ivy, gargled it to relieve sore throat and goiter, and made a preparation of it to treat mange in dogs; they also put a string of roots around babies’ necks to relieve teething problems, and put crushed leaves in milk (after cows were imported into the New World) to kill flies: the	Cherokee, Koasati	Fruits are rich in alkaloids, including solanidine, soladine, solasonine, solamargine and related glycoalkaloids, and alkamines (Perkins and Payne 1978, Hocking 1997)

<p>Koasati made a tea of it to wash out a sore mouth (Folsom-Dickerson 1965); Hocking (1997) found that people in Alabama had used it to treat thrush</p>			
<i>Spermacoce assurgens</i>	<i>cuaci-iche</i> (maybe <i>cuachtili</i> , snake, <i>ichcatl</i> , cotton, Veracruz), <i>l'herbe acouette</i> (extra herb, Dominica), woodland false buttonweed (Florida)	People in Veracruz use the herb in birth, and to treat snakebite (Vásquez and Jácome 1997); in Dominica it is made into a tea to treat colds (Von Reis 1973)	Dominica, Veracruz
<i>Spermolepis divaricata</i>	fool's parsley, forked seedscale, rough-fruited spermolepis	Plant poisonous, nauseating (Hocking 1997)	
<i>Styrax americana</i>	[American] snowbell, mock orange, spring orange, storax	Used as an expectorant, aromatic, vulnerary, for chest disease (Hocking 1997)	
<i>Tetragonotheca helianthoides</i>	Florida gensing, pine-land ginseng	In domestic medicine, presumably as a ginseng substitute (Hocking 1997)	Florida?
<i>Thaspium trifoliatum</i>	[purple] meadow-parsnip, round heart [plant], [golden] alexander	Vulnerary; in uterine disorders, chorea (Hocking 1997)	
<i>Tragia urticaefolia</i>	nettle-leaf noseburn, <i>pahí lambí</i> ( <i>pahí</i> , grass, <i>lambí</i> , sting, Koasati)	Named and perhaps used (Kimball 1994); at least a warning to be avoided	Louisiana
<i>Uniola paniculata</i>	sea oats (southeastern U.S.), <i>araña</i> (spider, Cuba), <i>espiga del mar</i> (seaside spike, Texas), <i>millo de mar</i> (seaside millet, Cuba), wild rice (Bahamas)	Indigenous people in the U.S. may have used the seeds as food as people in Central America use them today (Austin et al. 1991)	Southeastern USA, Caribbean

<i>Valeriana scandens</i>	<i>caoirin-leana</i> ( <i>caoirin</i> , little berry, <i>leana</i> , meadow, for <i>V. dioica</i> , Gaelic)	Starchy roots eaten (Hocking 1997); Moerman (1998) lists eight other species used across North America; Menominee and Meskwaki used <i>V. edulis</i> on cuts and wounds, and to stop bleeding; Menominee used <i>V. uliginosa</i> in several medicines	Menominee and Meskwaki	
<i>Vernonia angustifolia</i>	ironweed	Roots used as a bitter tonic, an alterative, an aperient, and in female disorders (Hocking 1997)		Sesquiterpene lactones glaucolide-beta and baldvernin
<i>Vernonia missurica</i>	Missouri ironweed, Drummond's ironweed, <i>a-'kai 'kawdl'a, ee-pa-la</i> (Matress plant, Kiowa)	Kiowa chewed blossoms, made pad for overnight bedding, used decoction to treat dandruff, and purple dye (Vestal and Schultes 1939); aqueous decoction used to treat dandruff; flowers give purple dye (Hocking 1997)	Kiowa	
<i>Veronica peregrina</i>	purselane speedwell, neckweed	Domestic medicine to treat scrofula (Hocking 1997)		
<i>Zigadenus densus</i>	<i>enú-su</i> (Catawba), black snakeroot, crow poison [crowpoison], Osceola's plume	Planted by the Natchez, whom the Catawba called <i>yi enú-su</i> (people of crow poison), because they planted it with their corn (Young and Siebert 2003); presumably, they did that to protect the corn from pests	Natchez	Other species known to contain colchicine-like alkaloids, zygadenine (plus hypotensive esters of zygadine), and germine

There is a single source for these species being used. Not enough details are given to provide more information on these species, but they are also part of Table 1.

**TABLE 3** *Species in Florida for Which No Documentation of Use Has Been Found, but That Are Related to Others Known To Be Used*

Species	Comments
<i>Acrostichum aureum</i>	Not in Moerman (1998); <i>Acrostichum danaeifolium</i> used, see text
<i>Aletris bracteata</i>	Not in Moerman (1998); other species used, see text
<i>Aletris obovata</i>	Not in Moerman (1998); other species used, see text
<i>Allium cuthbertii</i>	Not in Moerman (1998); other species used, see text
<i>Aristolochia tomentosa</i>	Not in Moerman (1998); other species used, see text
<i>Astragalus michauxii</i>	Other spp. in Moerman (1998)
<i>Astragalus obcordatus</i>	Other spp. in Moerman (1998)
<i>Astragalus villosus</i>	Other spp. in Moerman (1998)
<i>Cardamine bulbosa</i>	Not in Moerman (1998); other species used, see text
<i>Cardamine parviflora</i>	Not in Moerman (1998); other species used, see text
<i>Cardamine pennsylvanica</i>	Not in Moerman (1998); other species used, see text
<i>Ceanothus microphyllus</i>	Not in Moerman (1998); other species used, see text
<i>Cliftonia monophylla</i>	Honey source (Hocking 1997); not in Moerman (1998)
<i>Corydalis flavula</i>	Poison fide Lewis and Lewis (1977); other spp. in Moerman (1998)
<i>Corydalis micrantha</i>	Other spp. in Moerman (1998)
<i>Crataegus michauxii</i>	Not in Moerman (1998); other species used, see text
<i>Crataegus phaenopyrum</i>	Not in Moerman (1998); other species used, see text
<i>Crataegus viridis</i>	Not in Moerman (1998); other species used, see text
<i>Croton punctatus</i>	Not in Moerman (1998); other species used, see text
<i>Ctenium floridanum</i>	Roots of <i>C. aromaticum</i> used, see text; not in Moerman (1998)
<i>Dalea candida</i>	Root chewed or made into tea by Nebraska tribes (King 1984); see also Moerman (1998:192)
<i>Dalea purpurea</i>	Root chewed or made into tea by Nebraska tribes (King 1984); see also Moerman (1998:193)

<i>Dioscorea quaternata</i>	Hocking (1997) considered it a synonym of <i>D. villosa</i> , so perhaps same uses; also considered synonymous in <i>Flora of North America</i> (Committee 2002); not in Moerman (1998)
<i>Eryngium aromaticum</i>	Not in Moerman (1998); other species used, see text
<i>Gleditsia aquatica</i>	<i>Gleditsia triacanthos</i> used, see text
<i>Hymenocallis choctawensis</i>	Not in Moerman (1998); other species used, see text
<i>Hymenocallis crassifolia</i>	Not in Moerman (1998); other species used, see text
<i>Hymenocallis duvalensis</i>	Not in Moerman (1998); other species used, see text
<i>Hymenocallis godfreyi</i>	Not in Moerman (1998); other species used, see text
<i>Hymenocallis occidentalis</i>	Not in Moerman (1998); other species used, see text
<i>Hymenocallis palmeri</i>	Not in Moerman (1998); other species used, see text
<i>Hymenocallis puntagordensis</i>	Not in Moerman (1998); other species used, see text
<i>Hymenocallis rotata</i>	Not in Moerman (1998); other species used, see text
<i>Hymenocallis tridentata</i>	Not in Moerman (1998); other species used, see text
<i>Iris brevicaulis</i>	Not in Moerman (1998); other species used, see text
<i>Iris fulva</i>	Not in Moerman (1998); other species used, see text
<i>Iris tridentata</i>	Not in Moerman (1998); other species used, see text
<i>Litsea aestivalis</i>	Other spp. used (Hocking 1997); not in Moerman (1998)
<i>Lupinus diffusus</i>	None of FL spp. in Moerman (1998); other species used, see text
<i>Lupinus villosus</i>	None of FL spp. in Moerman (1998); other species used, see text
<i>Lupinus westianus</i>	None of FL spp. in Moerman (1998); other species used, see text

Species	Comments
<i>Mimosa quadrivalvis</i>	Not in Moerman (1998); other species used (Hocking 1997)
<i>Mimosa strigillosa</i>	Not in Moerman (1998); other species used (Hocking 1997)
<i>Neptunia pubescens</i>	Not in Moerman (1998); other species used (Hocking 1997)
<i>Orobanche minor</i>	Not in Moerman (1998); other species used, see text
<i>Pachyandra</i>	Ornamental ground cover (Hocking 1997); not in Moerman (1998)

<i>procumbens</i>	
<i>Passiflora pallens</i>	Not in Moerman (1998); other species used (Hocking 1997)
<i>Passiflora sexflora</i>	Not in Moerman (1998); other species used (Hocking 1997)
<i>Photinia pyrifolia</i>	Not in Moerman (1998); other species used (Hocking 1997)
<i>Phyllanthus abnormis</i>	Not in Moerman (1998); other species used, see text
<i>Phyllanthus liebmannianus</i>	Other species used, see text
<i>Phyllanthus pentaphyllus</i>	Other species used, see text
<i>Salix floridana</i>	Not in Moerman (1998); other species used, see text
<i>Smilax ecirrhata</i>	Not in Moerman (1998); other species used, see text
<i>Smilax lasioneuron</i>	Not in Moerman (1998); other species used, see text
<i>Smilax walteri</i>	Not in Moerman (1998); other species used, see text
<i>Spigelia gentianoides</i>	Not in Moerman (1998); other species used, see text
<i>Tradescantia ohiensis</i>	Slender shoots of <i>T. occidentalis</i> eaten (Yanovsky (1936); Meskwaki made a medicine with it (King 1984); see also Moerman (1998)
<i>Urtica chamaedryoides</i>	Not in Moerman (1998); other species used (Hocking 1997)

**TABLE 4** *Genera within Florida That Have Related Species Known To Be Used in Nearby Areas*

Genera	Sources
<i>Aeschynomene</i>	Morton (1981:273); Hocking (1997:19)
<i>Anemone</i>	Hocking (1997:50); Moerman (1998:72)
<i>Argythamnia</i> <i>Ditaxis</i>	Hocking (1997:68)
<i>Berlandiera</i>	Hocking (1997:109); Moerman (1998:121)
<i>Bigelovia</i>	Hocking (1997:112)
<i>Calamintha</i>	Hocking (1997:139)
<i>Callirhoe</i>	Hocking (1997:142); Moerman (1998:131)
<i>Campanula</i>	Hocking (1997:145); Moerman (1998:135)
<i>Carex</i>	Moerman (1998:137); Moerman (1998:137)
<i>Cupania</i>	Morton (1981:487)
<i>Dalea</i>	Morton (1981:307); Moerman (1998:192)

<i>Delphinium</i>	Morton (1981:215); Hocking (1997:248); Moerman (1998:196)
<i>Dyschoriste</i>	Hocking (1997:267)
<i>Elytraria</i>	Morton (1981:840); Hocking (1997:276)
<i>Gaillardia</i>	Hocking (1997:323); Moerman (1998:241)
<i>Hedyotis</i>	Hocking (1997:364)
<i>Hygrophila</i>	Morton (1981:841); Hocking (1997:385)
<i>Hymenopappus</i>	Hocking (1997:386); Moerman (1998:271)
<i>Hyptis</i>	Morton (1981:753, 758); Hocking (1997:388); Moerman (1998:273)
<i>Lygodesmia</i>	Moerman (1998:324)
<i>Macranthera</i>	Moerman (1998:327)
<i>Mimulus</i>	Hocking (1997:500); Moerman (1998:343)
<i>Nolina</i>	Hocking (1997:530); Moerman (1998:357)
<i>Ocimum</i>	Morton (1981:228, 773); Hocking (1997:536)
<i>Oncidium</i>	Hocking (1997:544)
<i>Palafoxia</i>	Moerman (1998:376)
<i>Philadelphus</i>	Hocking (1997:586); Moerman (1998:391)
<i>Physostegia</i>	Hocking (1997:592); Moerman (1998:397)
<i>Setaria</i>	Lentz (2000)
<i>Spermacoce</i>	Morton (1981:853, 878); Hocking (1997:743)
<i>Suaeda</i>	Hocking (1997:765); Moerman (1998:546)
<i>Trillium</i>	Hocking (1997:817); Moerman (1998:568)
<i>Valerianella</i>	Hocking (1997:837); Moerman (1998:587)
<i>Veratrum</i>	Hocking (1997:841); Moerman (1998:588)
<i>Zigadenus</i>	Hocking (1997:884); Moerman (1998:612)
<i>Zizyphus</i>	Morton (1981:502); Hocking (1997:885); Moerman (1998:614)

**TABLE 5** *Species Excluded from the Florida Ethnoflora Because of No Firm Evidence That They Are Native to the State*

Species	Morton	Hocking	Moerman	Comments
<i>Argemone albiflora</i>	–	(1997:68)	–	Blue-stem prickly poppy (Florida); sap used to treat sore eyes (Hocking 1997)
<i>Argemone</i>	(1981:241)	(1997:68)	–	Prickly nonnv (Florida). <i>cardo santo</i>

<i>mexicana</i>	397)			(holy thistle, Cuba); used to treat skin problems, as an emetic, and to kill head lice (Morton 1981, Foster and Hobbs 2002); see also Vásquez and Jácome (1997)
<i>Bidens pilosa</i>	(1981:913)	(1997:111)	–	Spanish needles (Florida), <i>romerillo</i> (little rosemary, Cuba); smoked as a tobacco substitute, as a vulnerary, to treat dysentery, and other problems (Morton 1981); see also Vásquez and Jácome (1997)
<i>Boerhavia diffusa</i>	(1981:191)	(1997:118)	–	Red spiderlings (Florida); used to treat a wide variety of ailments in the Caribbean (Morton 1981)
<i>Centella asiatica</i>	(1981:643)	(1997:169)	–	Pony food, spade-leaf (Florida); most of the uses are in Asia where it is known as <i>gotu kola</i> , among other names (Austin 1998c)
<i>Chamaesyce hirta</i>	(1981:425)	(1997:175)	–	Poll-pod sandmat (Florida), <i>lechera</i> (milky one, Cuba); considered antiasthmatic, antispasmodic, febrifuge, and diuretic, among other applications (Morton 1981, Hocking 1997, Vásquez and Jácome 1997)
<i>Chamaesyce hypericifolia</i>	(1981:427)	(1997:175)	(1998:153)	Graceful sandmat (Florida), <i>yerba de la niña</i> (little girl's herb, Cuba); Cubans consider it diuretic (Roig 1945)
<i>Chamaesyce maculata</i>	–	(1997:176)	(1998:153)	Spotted sandmat (Florida), <i>hierba de la golondrina</i> (swallow herb, Mexico); used for eye problems (Hocking 1997)
<i>Chamaesyce nutans</i>	–	–	(1998:153)	Eye-bane (Florida); Houma rubbed the latex on itchy skin, eczema, sores, and a decoction of the plant was given to infants (Speck 1941)
<i>Chamaesyce prostrata</i>	(1981:428)	(1997:175)	–	Prostrate sandmat (Florida), <i>hierba de la niña</i> (little girl's herb, Cuba), <i>golondrina</i> (swallow, Cuba)
<i>Chamaesyce thymifolia</i>	(1981:429)	–	–	Gulf sandmat (Florida); the latex is a drastic irritant purgative, used on skin problems; an essential oil that repels flies, fleas from dogs; it has a number of medical uses (Morton 1981)
<i>Chenopodium ambrosioides</i>	(1981:176)	(1997:178)	(1998:155)	Mexican tea (Florida), <i>apasote</i> (from Náhuatl, <i>epatl</i> , skunk, <i>tzotl</i> , filth, Cuba); widely used to expel intestinal worms

<i>Cyperus articulatus</i>	(1981:47)	(1997:239)	–	Jointed flat-sedge (Florida), <i>enea</i> (cattail, Cuba), <i>junco</i> (rush, Cuba); used to treat toothache, but ingestion said to cause drunkenness (Hocking 1997)
<i>Cyperus erythrorhizos</i>	–	–	(1998:190)	Red-root flat-sedge (Florida); seeds were cooked for mush by Kamia in Washington State (Hocking 1997)
<i>Cyperus odoratus</i>	–	(1997:239)	(1998:191)	Fragrant flat-sedge (Florida), <i>chintule</i> (Mexico); tea used to treat colic, cause drunkenness, and give luster and fragrance to the hair (Hocking 1997)
<i>Cyperus squarrosus</i>	–	–	(1998:191)	Bearded flat-sedge (Florida); acoma, Keres and Laguna tribes ate the roots (Moerman 1981)

Species	Morton	Hocking	Moerman	Comments
<i>Datura stramonium</i>	(1981:794)	(1997:245)	(1998:194)	Jimson weed (Florida), <i>chamico</i> (Cuba); a source of belladonna alkaloids well known around the world (Hocking 1997)
<i>Drymaria cordata</i>	(1981:212)	(1997:265)	–	West Indian chickweed (Florida); leaves eaten as salad; also used to treat headache, earache, liver, stomach, and kidney problems (Hocking 1997, Vásquez and Jácome 1997)
<i>Eclipta prostrata</i>	(1981:754, 924)	(1997:271)	–	False daisy (Florida); roots eaten, and leaves used to treat coughs and other maladies in Trinidad (Hocking 1997)
<i>Elusine indica</i>	(1981:30)	–	–	Goose-grass (Florida), <i>pata gallina</i> (hen's foot, Cuba), <i>grama de caballo</i> (horse grass, Cuba); seeds eaten, and the plants used to treat diarrhea, dysentery, and convulsions (Morton 1981)
<i>Erechtites hieracifolia</i>	(1981:927)	(1997:283)	–	Fire-weed (Florida), <i>achicoria de cabra</i> (goat's chickory, Cuba), <i>borraja</i> (borrage, Mexico); used as emollient, astringent, emetic, and to treat cough and hemorrhoids (Hocking 1997)
<i>Hippobroma longiflora</i> (= <i>Isotoma longiflora</i> )	(1981:897)	(1997:375)	–	Madam-fate (Florida), <i>revienta caballos</i> (horse breaker, Cuba); although it is a skin irritant and the fruit is toxic, it has been used to treat various diseases (Hocking 1997)
<i>Micromeria brownei</i> (= <i>Satureia</i> )	(1981:784)	(1997:497)	–	Savory (Florida), <i>poleo</i> (pennyroyal, Cuba); used to treat stomach and lung problems and other maladies (Hocking

<i>brownei</i> )				1997, Vásquez and Jácome 1997)
<i>Oxalis corniculata</i>	(1981:361)	(1997:554)	(1998:373)	Wood-sorrel, sour-grass (Florida), <i>vinagrera</i> [ <i>vinagrillo</i> ] (sour one, Cuba); leaves antiscorbutic, antipyretic, and used to treat bruises, corns, and for cleansing wounds (Hocking 1997, Vásquez and Jácome 1997)
<i>Oxalis violacea</i>	–	(1997:554)	(1998:374)	Wood-sorrel, sour-grass (Florida), <i>vinagrillo</i> (sour one, Cuba); considered antiscorbutic, diuretic; eaten in salads (Hocking 1997)
<i>Pedilanthus tithymaloides</i>	(1981:456)	(1997:572)	–	Devil's backbone (Florida), <i>itamo real</i> (royal <i>itamo</i> , Cuba), <i>gallito</i> (little rooster, Cuba), <i>zapatitos</i> (little shoes, Cuba); Millspaugh (1913) described the Florida plants as a distinct subspecies; Dressler (1957) wrote: "The plants were probably carried from Cuba at an early date by Spanish ships"; plants are caustic, irritating, emetic, toxic, and have been used in several medicines (Hocking 1997)
<i>Peteveria alliaca</i>	(1981:189, 366, 459, 514, 780)	(1997:582)	–	Guinea hen weed (Florida), <i>anamú</i> (specific Taino name, Cuba); considered antispasmodic, to stop convulsions, a counterirritant for toothache, and useful for many other maladies (Hocking 1997, Vásquez and Jácome 1997)
<i>Poinsettia heterophylla</i>	(1981:463)	(1997:297)	–	Wild poinsettia (Florida), <i>hierba lechosa</i> (milkweed, Cuba), <i>corazón de María</i> (Mary's heart, Cuba); used to treat pulmonary problems, malarial chills, erysipelas, and as a substitute for castor oil (Hocking 1997, Vásquez and Jácome 1997)
<i>Portulaca oleracea</i>	(1981:206)	(1997:625)	(1998:434)	<i>Lobuna</i> (Choctaw), purslane (Florida), <i>verdolaga</i> (Cuba); eaten as greens; medicinal (Morton 1981, Hocking 1997, Moerman 1998)
<i>Priva lappulacea</i>	(1981:750)	(1997:629)	–	Velvet-bur (Florida), <i>farolito</i> (little lantern, Cuba), <i>amor seco</i> (dry love, Cuba); used to treat wounds, headache, whooping cough, and other problems (Hocking 1997)
<i>Rhipsalis baccifera</i>	–	(1997:665)	–	Mistletoe cactus (Florida), <i>disciplinilla</i> (Cuba); used to tie up fractures (Hocking 1997)

			1997)
<i>Sida acuta</i>	(1981:533)	(1997:722) –	Wire-weed (Florida), <i>malva de caballo</i> (horse mallow, Cuba), <i>chak'misbil</i> (red broom, Maya, Yucatán), <i>chichipe</i> (Yucatan); branches are made into brooms; smoked as a stimulant and adulterant for marijuana; leaves contain ephedrine (Martínez 1969, Schultes and Hofmann 1979)
<i>Sida rhombifolia</i>	(1981:535)	(1997:722) –	Indian hemp, Indian tea (Florida), <i>malva de cochino</i> (Chinese mallow, Cuba); same use as <i>S. acuta</i>
<i>Waltheria indica</i>	(1981:558)	(1997:862) (1998:600)	<i>Malva blanca</i> (white mallow, Cuba), <i>hierba del pasmo</i> (Sinaloa); used from Tarahumara of Chihuahua (Ford 1975) to blacks of Guyana (Austin and Bourne 1992)

## ółaha,

“Caswalóhlik ilpá *ółaha*, hiná:yap naksahká sowi:sowik.” (One hears that it is time to eat the green corn, for now the cicada is calling) (Koasati; Kimball 1994).

“Nu’ti- hatkul’ha kai’?hade tci’pse ki:ye nuti-mi’ha. Wi-ti’-kuse? kuse’pi’i?koda kai’?hode. Iwi’ti-ki:ye yamu ke’hade atce’ha? mo’notuke’hade duke’hade waha’ matciri’k howe pa’i?howe motu’hawe ?kutci-we. Du’g mi- howe buru’kdugro’re mo’notuke’yu’we.” (Cut the top of the medicine on the side of the sunset. Cut the medicine vine behind the side of the sunrise. Put the root in water, and put a little back in the ground, in order that it may not vanish and there will be no more. It will come back again when you put it back in the ground) (Catawba; Speck 1934).

“I think it would be interesting to compare how ethnobotanists, anthropologists, and linguists do field work on plants some time: it’s a little like the story of the three blind men who feel different parts of an elephant” (Jack B. Martin, personal communication, 23 Oct. 2003).

# The Ethnobotany

# A

## *Abutilon*

(British gardener Philip Miller adapted the Arabic name for the plant, *aututilun*, used by Arabic physician Ibn Sina [Avicenna], who died in A.D. 1037)

*Abutilon permolle*. a. Tip of flowering and fruiting branch, b. Flower, from above, c. Flower longitudinally dissected, d. Pistil. e. Floral diagram, f. Fruit. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

*Abutilon permolle* (very softly pubescent)

*arepa* (the Taino word for a round cake of maize, typically served with butter and surrounding a filling of meat; the application to this plant is obscure, Belize)

butter print (from the fruit being used to make impressions on the surface of butter; a name shared with *A. theophrasti*, a common field weed in the midwestern United States)

butter weed (Bahamas)

daddy Joe (Bahamas)

[coastal] Indian mallow (Florida, Caribbean)

*sacmizbil* (*sak*, white, and *misbil*, broom, Maya, Yucatán; the related *Sida acuta* is *chak'misbil*, red broom)

velvet leaf [common] (Turks and Caicos)

velvety abutilon (Bahamas, a book name)

*zacxiu* (white herb, Maya, Yucatán)

*Abutilon theophrasti* was the first species of this genus that Europeans saw. These fiber plants were introduced through the Arabian trade route from Asia, and became known as Chinese jute, Chinese hemp, and Manchurian jute (Mabberley 1997). After the New World was discovered, Europeans found related species in the tropics. Probably, explorers were struck by the yellow flowers, or simply brought them back to Europe because the family (Malvaceae) was noted for producing medicinal species.

The original specimens and seeds of *A. permolle* were collected by Alexander von Humboldt in *America meridionalis* (Middle America). The plants were first named *Sida permolle* by Carl Ludwig von Willdenow (1765–1812), the director of the Berlin Botanical Garden. That name was created in his *Enumeratio Plantarum Horti Botanici Berolinensis* (List of Plants in the Berlin Botanical Garden), published in 1809. It was not until 1826 that the British botanist Robert Sweet moved the species into *Abutilon*; he did that in the *Hortus Britannicus* (Cultivated Plants of Britain).

The genus is also notable for mucilage that has been extracted from many species. Several species were exploited, and the extract was used as a poultice for tumors (Morton 1981). The mucilage serves as an emollient, and many use a decoction of it to clean wounds. In the Bahamas and Yucatán, the heated leaves are used to draw boils, and the decoction used to bathe sores. That usage is a continuation of medical application of the family that goes back hundreds, perhaps thousands, of years in Europe and the Americas. In that use, it is also like *Althea officinalis* (*Althea*, Greek, to heal; *officinalis*, of medicine), the mallow of Europe that provided the sweet originally called marsh mallow.

Emperor Charlemagne (742–814) thought so much of marshmallow that he ordered its cultivation. Doubtless, he had it used for both medicine and sweets. That original sweetmeat product was markedly different from our modern version—now the only plant extract marshmallows contain is the sucrose, and that sweetener does not come from mallows. Originally, the mucilage was extracted from marshmallow roots by boiling. It was used medicinally largely to soothe the skin and mucous membranes. That is essentially the use that *Abutilon* still has among some people.

The published information about the species does not record its use as a broom. However, the Maya common name clearly demonstrates that usage. In addition, in Yucatán, the fibers from the stems are made into twine.

*Acacia*

(Greek, *akakia*, tip, thorn, sharp point, used by Theophrastus, 372–287 B.C., and Dioscorides, fl. A.D. 40–80)

*Acacia. Acacia farnesiana . Acacia tortuosa . Both from Sargent 1905.*

*acácia* (Portuguese); *acacia* (English, Dutch, French, Spanish); *achachia* (Greek); *Akazie* (German); *akakia* (the juice, Coptic); *âqâqîya* (the juice, Arabic); *gaggia* (Italian)

*mimosa* (although applied to plants by at least 1619 in other languages, not appearing in English until ca. 1704); *mimosa* (from Latin *mimus*, Greek *mimos*, an actor or mime, with the feminine suffix *-osa*, resembling; said to allude to the mimicry of conscious life, French, Portuguese, Spanish); *Mimosa* (German)

*wattle* (origin uncertain, but appearing in Old English as *watul* ca. A.D. 700; possibly from Old Teutonic *wadlo-z*, to weave; originally meaning branches and twigs interwoven to form fences, walls, and roofs of buildings; also for the branches themselves, and then about 1810 to Australian legumes providing the branches)

*Acacia angustissima* (very narrow or slender)

*cantemó* (*kan*, yellow, *che'*, tree, *moc*, naked, Maya, Tabasco)

fern [prairie] acacia (Florida, Texas)

*guaje* [*huaj*] (*huaxin* [*hoatzin*, *hoaxin*, *uaxim*, *waxim*], simple term, often used for *Leucana*, Náhuatl, Yucatán); *guajillo* (little *guaje*, Sinaloa)

*kuká* (Guarajío, Sonora)

*palo de pulque* (*pulque* bush, Oaxaca)

*timbe* [*timbre*] (meritorius, Baja California, Oaxaca, San Luis Potosí)  
 white-ball acacia (Arizona, Texas)  
*xaax* [*xa'ax*] (having many scales, Maya, Yucatán)

***Acacia farnesiana*** (from the Farnese Palace Gardens of Rome. Palazzo Farnese was built on the Tiber River by the Farnese family, who commissioned it to an architect who then died; the project was completed by Michelangelo. Another palace then was built by the same family on the opposite bank and connected to Palazzo Farnese by a bridge. The opposite side building is called *La Farnesina*, well known to every Italian as it is the home of the Foreign Ministry, which is more often referred to as *Farnesina*, rather than *Ministero degli Esteri*.)

*aroma* [*aromo*] (fragrance, Puerto Rico, Yucatán, Nicaragua, Costa Rica, Colombia, Peru)

*bihi* (Zapotec, Oaxaca)

*binorama* [*vinorama*, *vignorama*] (Yaqui and Tarahumara, Baja California, Sonora, Sinaloa, Chihuahua)

*cashá* [*cashaw*] (variant of *Acacia*, Puerto Rico, Belize)

*cu'uca* (Mayo, Sonora)

*cuntich* (*cun*, bewitch, *tich*, abscess on the eyelids like a grain of corn, Maya, Belize)

*guacamaya francesa* (French parrot, Cuba)

*huisache* [*guisache*, *huichin*, *huizache*, *huixachin*, *uisatsin*] (Texas, San Luis Potosí, Nuevo León, Tamaulipas, Coahuila, south to Veracruz and Chiapas, from *huit-axin*, *huit* from *uitqui*, to strike, *axin*, unguent, Náhuatl, Mexico)

opoponax (healing juice, from Greek, southern USA)

sweet acacia (Florida)

*zubin-ché* [*zubin*] (*ché*, tree, Maya, Yucatán)

***Acacia tortuosa*** (twisted, referring to the pod)

*casia* [*akasee*] (variant of *Acacia*, Puerto Rico)

*huisache* (Durango, Aguascalientes)

poponax [wild] (healing juice, from Greek, Florida, Caribbean)

twisted acacia (Puerto Rico)

Europeans living around the Mediterranean were familiar with several species of *Acacia* before the New World was discovered (Flora Europaea 2003). They had names for them that they inherited from the Greeks and Romans (de Cleene and Lejeune 2002). When they arrived in the Americas, Europeans found even more species. Soon they were moving plants from continent to continent, and *A. farnesiana* was introduced from the Americas into Australia before there were European settlers there (Mabberley 1997). Not only were the flowers of several species pleasantly fragrant, but Mediterranean people knew the genus as a source of medicines.

The bark of *A. angustissima* is used to induce fermenting in *pulque* (see *Agave*), and in Yucatán as a remedy for enlarged spleen (Morton 1981). The species is high in tannin and is used in curing skins (Standley 1920–1926).

The wood of *A. farnesiana* is used. Bark and fruit provide materials for tanning and dyeing, and the fruit is used to make ink (Standley 1920–1926, Ford 1975). Gum from the trunk is used like gum-arabic and to cement broken china. Medicinally, the plant is used to treat dysentery, headache, dyspepsia, and bites from poisonous animals, particularly scorpions (Ford 1975, Morton 1981, Vásquez and Jácome 1997). Perfume is made from the flowers. The name *aromo* is said to be given because, when roots are chewed, they cause the spit to smell like excrement (Santamaría 1959).

A decoction of *A. tortuosa* leaves is applied for skin problems (Morton 1981). Root decoctions are also taken for gonorrhea and by women after child-birth.

### *Acer*

(The classical name of the maple tree, Latin *acer*, *aceris*, literally meaning sharp, perhaps from the early use of the wood for making spikes and lances; akin to Akkadian *arku*, long-tailed, tall)

*acero* (Italian); *Ahorn* (German); *arce* (Spanish); *érable* (French); *asarot* (French)

*awohátqua* (Onondaga)

*ayan* 'to 'hayudi' (*ayan*, tree, to *hi*, blue, *ayudi*, wood; the bark made a blue dye, Biloxi)

*héno* (Muskogee)

*lønne* [*lønn*] (wages or pay, Norwegian) maple (from Old English *mapel* or *mapul*, originally used in the compound *mapeltréow*, maple tree, akin to Old Saxon *mapuldur*)

*schiechi kiminschi* (*kiminschi*, plant, Delaware)

***Acer negundo*** (a name from Hindi, *nirgandí*, because of the similarity of its leaves to *Vitex negundo*)

*acero* (Italian); *arce* (Spanish, Texas); *érable a giguère* (haunch maple, Quebec)

*acezintle* [*acecincle*, *acecinte*] (from *acezintli*, literally bad herb, Náhuatl, Chiapas)

ash-leaved maple

[California] box elder [boxelder, box-alder, box-tree] (in use by 1787, presumably because the wood was used for making boxes, and the leaf's similarity to the elder, *Sambucus*)

*fresno de guajuco* (ash *de guajuco*, Texas)

*Acer. Acer negundo . Acer rubrum .  
Acer saccharum . Acer saccharinum .  
All from Sargent 1905.*

*kaw-señ-añ-daw* [*kaw-sei-ai-daw*] (*daw*, tree, Kiowa)

Manitoba maple

*mistikosokaw* (tree sugar, Cree); *sokawahtik* (sugar tree, Cree)

*nahosh* (Winnebago)

*ósako* (Pawnee)

*palo de venagre* (vinegar tree, Mexico)

*raxoch* (Guatemala)

*sool* (Navajo)

*tashkadan* (Dakota)

*zhaba-ta-zhon* (*zhaba*, beaver, *zhon*, wood, Omaha-Ponca); *zha'-be-ta-*

*zhon* (*zha'-be*, beaver, *ta*, his, *zhon*, wood, Osage)

***Acer rubrum* (red)**

*ashak homeche* [*asaykhô:mî:cî*] (*ashak*, acorn, *home*, bitter, *che*, little; an allusion to a pestle made from red maple altering the taste of acorn meal, Mikasuki)

*chukchu* (Choctaw. Swanton 1931 wrote that mortars from them gave food a taste “sufficiently bad to ruin one’s stomach”)

*cicig'me'wc* (Ojibwa); *cicigimé-wic* (Potawatomi)

*héno* (Muskogee); *hinô* [*haino*] (Creek, cf. Simmons [1822] 1973)

*ipfûmithatká* (*ipfo*, squirrel, *im*, its, *ittó*, tree, *hatká*, white, Koasati)

*plaine* (plane tree, from Old French *plasne* from the 1300s, itself derived from *Platanus* because of the broad leaves, Quebec); *plaine rouge* (red plane tree, Quebec)  
 red [scarlet, soft, swamp] maple  
*she-she-gum-maw-wis* (sap flows fast, Ojibwa)  
*yap sake'here* (red tree, Catawba)

***Acer saccharum* (sugar)**

*achsüñamihschi* (*achsüña*, sugar, *mihschi*, tree, Delaware); *a'nina'tig* [*adjabubi'mi*, *inenatig*, *ininâtig*, *nin-au-tik*] (*migit*, tree, *nin*, our, Ojibwa); *inina'tig* (our tree, Potawatomi); *kisinamic* [*kisinamîc*] (cold tree, Potawatomi); *senamishi* (cold timber, Meskwaki)  
*can-n'* (*can*, tree, *n'*, sap, Osage); *jan-ni* (Kansa, Omaha-Ponca); *nanni* (Iowa)  
*chan-ha son* (*chan-ha*, bark, *son*, pale or whitish, Dakota); *nan-sank* (*nan*, wood, *sank*, real, genuine, Winnebago)  
*chukchu chito* (*chukchu*, maple, *chito*, big, Choctaw); *chukchu hapi champuli* (*chukchu*, maple, *hapi*, salt, *champuli*, sweet, Choctaw)  
*érable a sucre* (sugar maple, Quebec)  
 [Caddo, chalk, Florida, hard, rock, striped, sugar, northern sugar] maple  
*o-loñ-da'ke'li'* (tree sap, Oneida); *u-ren'-na'-kri* (tree sap, Tuscarora)  
*ta'niju'-ra* (water wood, Winnebago)  
*thenomeysee* (Shawnee, fide Edgar 1891; *mihschi*, tree, is the Delaware cognate for the second element)  
*waronawoenta girhit* (*waronawoenta*, sugar, *girhit*, tree, Onondaga)  
*Zuckerbaum* (sugar tree, German); *Zuckerholz* (sugar [maple] woods, German)

Europeans had lived with maples their entire history, and none of their native species has ever been used to produce sugar (Cheatham et al. 1995). However, when Europeans arrived in the New World, they found indigenous people harvesting sap from maples and other genera to produce a sweet drink and to use in cooking (Henshaw 1890). Although it may be difficult to comprehend from the perspective of this century, with its immediate and cheap sources of sugar, maples were an important source of sweets to indigenous Americans. History notes that, to the indigenous people in Quebec, *Acer saccharum* “affords great quantities of a cooling and wholesome liquor from which they make a sort of sweet” (Jefferys 1760 in Hedrick 1919). The month of March to the Menomini was *sho-bo-maw-kun-ka-zho* (sugar moon).

In 1870, the Winnebago and Ojibwa (Chippewa) sold the Northwest Fur Company 15,000 pounds of sugar a year made from this species (Hedrick 1919). During 1880 the United States produced 36 million pounds of maple sugar (Henshaw 1890). Considering that it took 30 to 40 gallons of sap to produce 1 gallon of syrup, the harvest was considerable. Some estimated that it took 4 gallons of syrup to yield 1 pound of sugar (Cheatham et al. 1995). In spite of the importance of these trees, they were commercially

over-shadowed by other sugar sources, perhaps because they could not produce enough to meet the demand.

Of the three maples in Florida, we have records of all being used for sugar (Smith 1933, Yanovsky 1936, Cheatham et al. 1995, Moerman 1998). *Acer negundo* was used for sugar by at least the Chiricahua (Arizona), Cheyenne (Montana and Oklahoma), Cree (Alberta, Saskatchewan to Montana), Dakota (Montana, Dakotas, Nebraska, Minnesota), Ojibwa (upper Midwest and southern Ontario), Mescalero (New Mexico to Texas), Montana (Montana), Omaha (Nebraska), Pawnee (Missouri River region), Ponca (Nebraska, South Dakota), and Winnebago (Wisconsin). *Acer rubrum* was used by the Abenaki (Quebec), Algonquin (New England, Quebec), Iroquois, including Cayuga and Onondaga (New York and Quebec). *Acer saccharum* was a source for the Algonquin including the Miami, Dakota, Iroquois, Malecite (New Brunswick), Menomini (Wisconsin), Meskwaki (Iowa), Micmac (Nova Scotia), Mohegan (Connecticut), Ojibwa, and Potawatomi (Wisconsin).

Yanovsky (1936) found records that the inner bark of *A. rubrum* was used to make bread.

The Koasati (southern Tennessee, northern Alabama) drank a medicinal infusion of red maple bark, mixed with *Ulmus americana* and *Nyssa sylvatica*, and washed wounds with it (Taylor 1940). Seminoles used red maple to treat “Ballgame Sickness” (sores, back or limb pains, hemorrhoids) (Sturtevant 1955). Red maple bark (collected from injured areas on the tree) is mixed with pine, live oak, laurel oak, pop ash, rabbit tobacco, wild persimmon, strap fern, gum bark (strangler fig), mulberry bark, and elderberry to treat postpartum problems, back pain, and postmenopausal ailments. The medicine, known as *ahecha keeke* (caretaking), is taken orally and used in a vaginal wash. Men are forbidden to touch this medicine (Bennett 1997).

Box-elder wood was used in ceremonies, to cook meat, for prayer sticks, and pipe stems. The Cherokee used red maple wood to make baskets, for carvings, bowls, lumber, and furniture (Hamel and Chiltoskey 1975). The Seminoles also used red maple wood to make spoons, arrowheads, and ox yokes (Bennett 1997). Sugar maple wood was more important than most other species (Moerman 1998). Box-elder wood was used to make charcoal for ceremonial painting and tattooing (Gilmore 1919).

Kalm ([1753–1761] 1972) noted that the European settlers of New England were making a dark blue dye of *A. rubrum*. That was probably a variation of a technique learned from indigenous people. However, use of the bark to make black ink was a decidedly European twist.

The Cherokee (western Carolinas) took an infusion of red maple and box-elder bark for cramps, dysentery, “female troubles,” measles, and hives, and they used it to bathe sore eyes (Hamel and Chiltoskey 1975). Farther north, the Potawatomi and Mohegan made medicines from red maple (Smith 1933, Cheatham et al. 1995). Sugar maple had several medical uses, including as a blood purifier, against itch, and as an eye medicine, cough remedy, and expectorant (Cheatham et al. 1995, Moerman 1998). The Meskwaki and Ojibwa took an infusion of box-elder inner bark as an emetic (Moerman 1998).

### *Achillea*

(Named in honor of the hero of the *Iliad*, Achilles, in Greek *Akhilleus*, son of Peleus and Thetis, who learned from Chiron the Centaur the healing properties of the plant)

*cruaidh lus* (*cruaidh*, sword, *lus*, herb, Gaelic)

***Achillea millefolium*.** a. Habit, b. Stem segment showing detail of leaves, c. Flower head. d. Female and male flowers, e. Seeds. *Drawn by Regina O. Hughes.* From Reed 1971.

*èarr thalmhuinn* (*èarr*, noble, *thalmhuinn*, powerful, Gaelic)

*herba militaris* (military herb, name said to have been given the plants after the Greek Trojan Wars because of the use in staunching the wounds of soldiers)

*lus chosgadh na fola* (*lus*, herb, *chosgadh*, staunching, *na*, of, *fol*a, blood, Gaelic)

milfoil (from Latin *mile*, *milk*, thousand, *folium*, leaf, appearing in English about A.D. 1000); *milefólio* (Portuguese); *milefolio* (Spanish); *milénrama* (Spanish); *millefeuille* (French)

*Schafgarbe* (sheep-yarrow, German)

***Achillea millefolium*** (thousand-leaf)

- a'djidamo'wano* (squirrel tail, Ojibwa)
- alcanfor* (camphor, Veracruz, Yucatan)
- alhucema* (a name usually applied to *Lavandula*, Central America)
- astaweskotawan* (to put out a campfire, i.e., relieves burning pain, Cree); *kishkatoa'soanûk* (flying squirrel tail, Potawatomi); *nokwe'sikûn* (perfume reviver, Potawatomi)
- athair-thalmhainn* [*cathair-thalmhainn*] (*athair*, father, *thallmhainn*, powerful, Gaelic)
- bloodwort
- ciento en rama* (hundred branches, Mexico)
- cola de ardilla* (squirrel tail, Central America)
- common milfoil; *milenrama* [*milen rana*] (Spain, Central America); *mil-folhas* (thousand-leaf, Brazil); *milhojas* (thousand-leaf, Central America); thousand-leaf [-seal]
- fani hasambish holba* (*fani*, squirrel, *hasambish*, tail, *holba*, like, Choctaw)
- flora de la pluma* (feather flower, Spanish)
- hank-sintsh* (*hank*, woodchuck, *sintsh*, tail, Winnebago)
- herbe à dindes* (turkey herb, Quebec)
- hierba del soldado* (soldier's herb, Central America)
- ihiseeyo* (cough medicine, Cheyenne)
- miskigonimaskigiah* (head medicine, Cree); *ongunimasgigah* (bone medicine, Cree)
- nose-bleed (USA, England)
- plumajillo* (little feather, Coahuila, Hidalgo, Puebla, Valley of Mexico, Veracruz, and others)
- sanguinary (for the blood)
- sereno de invierno* (winter serenity, Dominican Republic)
- taopi pexuta* (wound medicine, Lakota); *xante canxlogan* (cedar weed, Lakota)
- tlanqueuetzal* (remain kneeling, recorded 1615 by Ximénez for Aztecs, Náhuatl, Mexico)
- we'-ts'a-çin-dse e-gon* [*wetsaoindse egon*] (like a rattlesnake's tail; *we'-ts'a*, snake, *çin-dse*, tail, *e-gon*, like, Osage)
- yarrow [common, fragrant, western] (etymology uncertain, dating from ca. A.D. 700; cognate with Old English *gearwe*, Dutch *garwe*, German *garbe*)

According to legend, Achilles stopped the flow of blood from the wounds of his Myrmidon warriors with this plant (Baumann 1993, Quattrocchi 1999). Although the name and fame of this herb dates from the classical Greeks, its association with people in the Old World long predates that period. Yarrow was found in a Neanderthal grave dating back 60,000 years (Swerdlow 2000). Therefore, Europeans were well acquainted with the plants when they arrived in the New World, and there is still debate as to whether or not it is native here (Mabberley 1997, Diggs et al. 1999). Given yarrow's widespread use by

indigenous people, there were surely some native forms and the species was likely circumboreal.

Use by the Illinois and Miami tribes on cuts was first reported in 1724 (Vogel 1970). The Cherokee used milfoil to treat spitting blood, bloody diarrhea, fever, bloody urine, and to aid sleep (Hamel and Chiltoskey 1975). The Chickasaws used it in a remedy for cramps in the neck (Swanton 1928b). The Creeks used the plant as a toothache remedy (Swanton 1928a). Additionally, the plant was used medicinally by at least the Abenaki, Algonquin, Bella Coola, Blackfoot, Carrier, Chehalis, Chipewyan, Ojibwa, Clallam, Cowlitz, Cree, Crow, Delaware, Flathead, Gitksan, Gosiute, Haisla, Hesquiat, Karok, Kallam, Kutenai, Kwakiutl, Lakota, Lummi, Mahuna, Makah, Malecite, Mendocino, Menomini, Micmac, Mohegan, Montagnais, Nitinaht, Ojibwa, Okanagan-Coville, Okanagon, Paiute, Potawotomi, Quileute, Quinault, Saanich, Salish, Shuswap, Skagit, Slave, Snohomish, Squaxin, Swinomish, Thompson, Winnebago, and Yuki (Gilmore 1919, King 1984, Moerman 1998, Marles et al. 2000). Others used it to make tea, as incense, and as a smudge to keep mosquitoes away (Moerman 1998).

Yarrow contains chamazulene, among other components of its essential volatile oils. That compound acts as an anti-inflammatory, antiallergenic, and helps stop spasms (Swerdlow 2000).

### *Acmella*

(Diminutive of Greek *akme*, a point, edge, blossom, in reference to the taste of the foliage)

*Acmella oppositifolia* (having leaves opposite each other on the stem)  
(=*Spilanthes americana*)

*Acmella oppositifolia*. From Britton and Brown 1898.

*abecedária* (alphabet plant; named this because it is locally believed that the plant will facilitate the tongues of babies and make them talk more easily, Brazil)

*agrião bravo* [*do Brasil, Pará*] (wild and bitter [from Brasil, Pará], Brazil)

*botão de ouro* (gold button, Brazil); *botón de oro* (gold button, Spanish); *botoncillo* (little button, Darien, Panama, Colombia, Ecuador)

*calabaza* (little head)

*chisaca* [*risacá*] (Chocó, Panama and Colombia)

*cresson de Pará* (cress from Pará, French)

*flor de María* (Mary's flower)

*grana de oro* (golden grain)

*guaca* (Colombia)

*jambu* (from *ya'mbu*, Tupí, Brazil); *jambu* [*mambu*] *açu* (big jambu, Tupí, Brazil)

*ni* (Huastec)

*pimenta d'agua* (water pepper, Brazil)

*quemadera* (it burns, Colombia)

*rem* [*rem'q en*]

spot-flower [spotflower] (Florida)

*tripa de gallo* (chicken guts)

*xux* (wasp, Maya, Yucatán)

*yoyo quemado* (burned yoyo, Colombia)

For many years *Acmella* was considered either a synonym or subdivision of *Spilanthes*, but that changed in the mid-1980s when it was reinstated as a separate genus (Mabberley 1997). There are about 30 tropical species in *Acmella*, but none is native to Europe. Spot-flower was first described by Thomas Walter in 1788. As a result of complications, however, Walter's species name cannot be used, and the correct binomial is *A. oppositifolia*.

Several species in the genus have become pantropical weeds, perhaps because people carried them purposefully. In South America the Brazilian or Pará cress, *A. oleracea*, is a medicinal and edible plant (LeCointe 1947). However, most people find its spilanthol-induced tingling of the tongue unpleasant (Mors et al. 2000).

The Tupisa Chocó eat the leaves, raw or cooked, and they are used to relieve liver trouble (Duke 1968). In Colombia the herbs are medicine for sore throat and mouth sores, and are used as cooked greens (Morton 1981).

*Botoncillo* contains the same spilanthol that *S. oleracea* does, and produces a similar tingling. Brazilians use the plants in a variety of medicines for mouth and throat ailments, but still consider it an "obligatory condiment in some regional dishes" (Mors et al. 2000).

### *Acoelorrhaphe*

(Greek, *acoelo*, without the hollow, *rhaphe*, seam, because the seeds lacks the impressed raphe of many palms)

*Acoelorrhaphe wrightii* (named for Charles Wright, 1811–1885, a botanical collector in Cuba and elsewhere)

*Acoelorrhaphe wrightii* a. Habit, b. Upper part of petiole and hastula. c. Flower from above, d. Flower side view, e. Flower longitudinally dissected, f. Floral diagram, g. Fruiting inflorescence (left) and branch from fruiting inflorescences (right). Drawn by Priscilla Fawcett. From Correll and Correll 1982.

*chi-it* (also the name of *Thrinax radiata* in Yucatán, Maya, Belize)  
Everglades palm (Bahamas)

*guano prieto* (*guano* is a Taino name for a tree, presumably originally  
a *Ceiba*; *prieto*, black, meaning false, Cuba)

hairy tom [palmetto] (Belize)

*harádan* (Garífuna, Nicaragua)

palma (Belize)

palmetto (Belize)

papta (corruption of “palmetto,” Belize)

[Honduras] *pimenta* [*piementa pim-iént, pim-int, prementa, primenta*]  
[palm] (“pimenta” and other variants are corruptions of “palmetto,”  
Belize)

*tasiste* [*taciste*, *ta-sis-te*] (ta, front, sis, something fresh, *te*’, to collect, Maya, Belize, Yucatán)

The Everglades palm is monotypic, and its single species grows from southern Florida, through the Bahama Islands, in Cuba, and from Chiapas, Tabasco, Yucatan, and Quintana Roo in Mexico, south to Nicaragua. From there it is apparently disjunct to northern Colombia.

The species was first named *Copernicia wrightii* in 1866 by German professor of botany at Göttingen, August H.R. Grisebach (1814–1879), and by the director of the royal garden in Herenhausen, Hermann A. Wendland (1825–1903). Then Wendland realized that the species did not belong with that genus, and he gave it the new generic name *Acoelorrhaphe* in 1879. Finally, the Italian world specialist on palms Odoardo Beccari (1843–1920) created *Acoelorrhaphe wrightii* in 1908.

Leaves are used for thatch and rope; fruits are edible (Morton 1968b). In Belize, the plants are used for food, medicine, construction, and in making products (Balick et al. 2000). Scott Zona (personal communication 2003) informs me that in Cuba, nurserymen now use trunks of this palm as supports for climbing aroids.

### *Acrostichum*

(Greek *akrosticon*, *akros*, terminal; *stichos*, a row or line, a reference to the fertile apical portion of the leaf)

***Acrostichum aureum*** (golden)

*helecho* (fern, Belize)

*payuri* (Carib, Suriname)

tiger bush (Belize)

***Acrostichum danaeifolium*** (*danae*, the fern genus *Danaea*, *folium*, leaf, meaning that the leaves resemble those in the fern *Danaea*)

**Acrostichum.** *Acrostichum aureum* , a. Blade on left, stipe on right, b. Base of stipe with adventitious roots and scales, c. Above, pinnule attachment; below, section of stipe showing marginal spine, d. Areoles in midrib region of pinna. e. Paraphyses.

*Acrostichum danaeifolium* , a. Sterile blade on right, section of sterile stipe on left. b. Fertile blade on right, stipe of fertile blade on left. c. Base of stipe with scales and scale scars below; middle of blade showing pinnae attachment above, d. Single pinna. e. Areoles in the midrib region of pinna. f. Paraphyses. Both drawn by Priscilla Fawcett. From Correll and Correll 1982.

*avenção* (based on *avenca*, fern, so “big fern,” Brazil)  
giant fern (Bahamas)

*tapintó:bi* [*tapintcobi*] (big fern, Mikasuki)

*lakko* [*toca:rakko*] (*lakko*, big, Creek)

The genus *Acrostichum* and the species *A. oureum* were both created by Linnaeus in *Genera Plantarum* in 1754. It was not until 1810 when *A. danaeifolium* was described from the state of Santa Catarina in southern Brazil where it had been collected by Georg Heinrich von Langsdorff (1774–1852).

*Acrostichum aureum* is used in Belize as food and medicine (Balick et al. 2000). Young leaves from this pantropical species are also used as food in Malesia, and the old leaves are used to thatch houses in Vietnam (Mabberley 1997).

Seminoles use *A. danaeifolium* as a febrifuge; an infusion of plant taken and rubbed on the body to reduce high fevers (Sturtevant 1955). Fiddleheads (unfurled fronds) are edible and eaten like asparagus (Morton 1968b).

### *Actaea*

(From Latin *actaea*, Greek *aktea*, the name of the elder, *Sambucus*, used by Pliny, A.D. 23–79; the name was transferred to these plants by Linnaeus, perhaps because of the similarity of the leaves)

baneberry (“bane” as used here means “poison,” and was combined with “berry” by 1755)

*barba di capra* (goat’s beard, Italian)

*Christophskraut* (Saint Christopher’s herb, German); Herb-Christopher (the name of European *A. spicata*, which Turner called Christophoriana or “Grapewurt, because it hath many blacke berries in the toppes lyke grapes” in 1548); *herbe de Saint Christophe* (French); *hierba de San Cristobal* (Spanish)

*trollbaer* (troll berry, Norwegian)

*wasgobîdji’bikeok* (sweet root plant, Potawatomi); *wi’cosidji’bik* (drawing root, as in drawing out poisons, for *A. rubra*, Ojibwa)

### *Actaea pachypoda* (with a thick flower-stalk [pedicel])

American herb-Christopher

baneberry

cohosh [blue, white, cohush] (“cohush” was recorded by 1796 for an *Actaea*, although the species is in doubt; authors in the mid-1800s said that it was from an “Indian word,” although neither region nor tribe is indicated)

China-berry [chinaberry] (usually applied to *Melia azedrach*, Meliaceae)

doll’s eyes (“doll” has been used in English since ca. 1560 as a pet form of the name *Dorothy*, apparently, it was not until ca. 1700 when the word was applied to an image of a human, particularly one used by girls as a plaything; Henry David Thoreau wrote in 1852 that *Actaea* fruits “have just begun to be white, as if they contained a pearly venom—wax white with a black spot...imp-eyed”; in other words, like a doll’s white china eyes)

false-aloe (maybe because both are laxative?)  
*masqua-mitruin* (bear's root, because bears are believed to eat the roots, Plains Cree)  
 necklace-weed [necklaceweed] (alluding to the spikes with fruits on them like beads on a necklace)  
 pearl berry  
*racine d'ours* (bear's root, Quebec)  
 rattlesnake herb; rattlesnake master (a name usually given to *Eryngium*)  
 richweed (Virginia)  
 [buttonj-snakeroot (usually applied to *Eryngium*, especially *E. yuccifolium*)  
 toadroot (maybe because both toads, *Bufo*, and plants are poisonous)  
 white baneberry  
 white-beads [-berry]

When Linnaeus created *Actaea* in 1753, he was familiar with the European species *A. spicata*. It was not until 1821 when Steven Elliott (1771–1830) described *A. pachypoda* in his flora of the Carolinas. There are now eight species known in the genus, with two in Europe, and two species and their hybrid in the New World (Mabberley 1997).

The Blackfoot took a decoction of the roots to treat colds and coughs (Moerman 1998). The Cherokee made an infusion to treat itch, as a gargle, for toothache, and they and the Meskwaki used it to rally patients nearing death (Hamel and Chiltoskey 1975). The Iroquois used the plant to treat men's urinary problems. The Menomini also used it to relieve headache caused by eye strain (Foster and Duke 1990). The Ojibwa gave root decoctions to children and adults with convulsions (King 1984).

People in Canada, presumably the Cree, made a decoction of roots with spruce fir (*Abies*) to treat gastric distress. Others have used the plants as an emetic and purgative (Hocking 1997).

Constantine Samuel Rafinesque (1830) was among the first in America to note the medicinal properties of *Actaea*. He wrote that the roots were repellant, nervine, and used to treat debility in Canada. Millspaugh (1892) was not as impressed with the American species, and instead recommended the European *A. spicata*. He considered *Actaea* useful for "reflex uterine headache," and some types of rheumatism. Later it was used for coughs, menstrual irregularities, colds, and constipation. It is thought that *A. pachypoda* may benefit circulation (Foster and Duke 1990), but ingestion of the plant may cause severe gastrointestinal inflammation and contact with the skin may result in skin blisters.

### *Adiantum*

(Pliny, A.D. 23–79, used the Latin *adiantum* for the maiden-hair fern; Greek *adiantos*, unwetted or "wetproof," not capable of being wetted, referring to the leaves that shed water or raindrops and remain dry)

*Adiantum capillus-veneris* (Venus's hair)

*adiante* (adiantum, French, from 1575); *adianto bianco* (white adiantum, Italian, from 1551)

*avenca* (fern, Brazil); *avenca comum* (common fern, Brazil)

black maiden-hair [maidenhair] (“maidenhair” was in use by ca. A.D. 1450 for *A. capellusveneris*); common maiden-hair; southern maiden-hair

*cabello de Venus* (Venus’s hair, Brazil); *capelevenere* [*capil uenere*] (Venus’s hair, Italian, from 1551); *capillaire* (hair, Quebec); *cheveux de Venus* (Venus’s hair, French, from 1550); Venus’s hair [fern, from 1568] (Venus heyre)

*chib* (Maya?)

*cuamaquistli* (variant of *quauhmoctli*, snake jaws?, Náhuatl, Mexico)

*culantrillo* (little coriander, San Luis Potosí, Nuevo Leon, Central America); *culantrillo del pozo* (little coriander of wells, Spain)

dudder grass [dodder grass] (from *dothier* or *dither*, trembling, shutter, or shiver, from 1658, now dialectic)

*failtean flonn* (*failtean*, head-band, *flonn*, white, Gaelic)

*Frawenhar* [*Frauen haar*] (maiden hair, German, from 1542)

*iunkfrawen hare* (young maiden’s hair, German, from Turner [1548] 1965); *Junckfrawenhar* (young maiden’s hair, German, from 1542); maiden-hair [maidenhair, true maiden haire] [fern] (from 1597)

*ochquewi miecheken* (*ochquèu*, woman, *milach*, hair, Delaware)

*steenruyte* (stone rue, Dutch, from 1549)

*weewilsquee* (Shawnee, fide Edgar 1891; probably cognate with the Delaware)

***Adiantum melanoleucum*** (black and white) fragrant maidenhair

***Adiantum tenerum*** (tender, soft)

black stick (Belize)

[brittle] maidenhair [fern] (USA, Belize)

*palo negro* (black stick, Belize)

*roc-che-cwan* (*roc*, rock, *che*’, *plant*, *kwa*’, *pain*; mixture of English and Maya, Belize)

There are comparatively few ferns used in medicines. Perhaps one of the oldest known from Europe is *Adiantum capellus-veneris*. That Latin epithet was first applied to it by Pseudo-Apuleius about the 4th century A.D. (Meyer et al. 1999). Herbalists since the mid-1500s have praised this fern, and many of its names are derived from that old Latin. Culpeper (1653), for example, recommended it to treat “coughs, asthmas, pleurisy, etc., and on account of its being a gentle diuretic, also, in the jaundice, gravel [kidney stones], and other impurities of the kidneys.”

Off the Galway coast of Britain, people collected the fronds, dried them, and used them as a tea substitute (Hedrick 1919). However, many considered that drink expectorant, astringent, and a tonic for coughs, throat problems, and bronchitis (Foster and Duke 1990). Kalm ([1753–1761] 1972) comments that *herba capillaris* (*A. pedatum*) was exported to Europe in the 1740s when he was in Quebec, being “reckoned preferable

in surgery to that which we have in Europe,” which he identified as *A. capellus-veneris*. Locally, the French were using it for a tea to treat “consumptions, coughs, and all kinds of pectoral diseases.” He continues, “This they have learnt from the Indians.”

Among the few records of *A. capellus-veneris* use in North America is by the Mahuna of California and Navajo of northeastern Arizona. The Californians used it to treat rheumatism, and in Arizona, they used it to treat bee or centipede stings and mental problems (Moerman 1998). The Mexicans boiled the fern into tea used to treat retarded menstrual periods (Ford 1975). Hann (1986) listed *Adiantum* sp. as being used by the Apalachee; the only species known in their range is *A. capellus-veneris*. Surely, the other two native Florida maiden-hair ferns were also used.

We also know that the related *A. pedatum* was widely used in the southeastern United States and elsewhere. Cherokees called it *ka'ga-asguntagi* (crow's shin, Mooney 1885–1886). Among the eastern people using this species were the Cherokee, Menomini, Meskwaki, Micmac, and Potawatomi (Smith 1933, Moerman 1998). A number of groups in western North America from British Columbia to California also used this species. Uses of this species are the same as for *A. capellus-veneris* (Foster and Duke 1990, Moerman 1998).

Although nothing has been found about Old World people washing the hair with ferns, that was a practice with both *A. capellus-veneris* and *A. pedatum* in the New World (Foster and Duke 1990). Indigenous Americans considered the maiden-hair ferns especially good for making their hair shiny (Foster and Duke 1990). One has to wonder if that was not the original reason the Old World plants were compared to Venus's hair.

### *Aesculus*

(The Latin name for a tree, probably originally for the Italian oak; akin to Greek *askra*, Akkadian *isu*, *esu*, Summerian *gis*, tree)

*Aesculus pavia* (for Peter Paaw, 1564–1617, Dutch botanist)

*atai* (mostly given to *A. flava*, Choctaw); *vlv* (mostly given to *A. flava*, Muskogee)

[flame, scarlet, red, woolly] buckeye (“buckeye” is said to have been applied by the 1840s, “from the hilum of the fruit [seed] having the appearance of a stag's eye”)

firecracker plant (an allusion to the red flowers)

fish poisonbush

*ta-shka'-hi* (Osage, probably for *A. flava*)

The first Europeans who arrived in the New World were completely unfamiliar with *Aesculus*. The Old World species, *A. hippocastanum*, native to Albania, Greece, Bulgaria, and Yugoslavia, was introduced into Europe in 1550 (Linnaeus [1753] 1957, Millspaugh 1892, Clapham et al. 1987). Called the horse chestnut, the tree reached England in the 1600s and was first cultivated there by John Tradescant in 1633 (Millspaugh 1892).

Not long afterward, in 1696, Leonard Plukenet recorded a new species, which he called “*Saamouna pisonis seu siliquifera brasiliensis arbor, digitalis foliis serratis*,

*floribus teucris purpureis* (“Saamouna” for fish or Brazilian tree with siliques, palmate leaves with serrate leaflets, purple flowers resembling *teucrium*). Because of confusion over the origin of his specimen, he thought the plants were from Brazil. Even Linnaeus, when he thankfully changed that long name to *Aesculus pavia*, listed the species from the Carolinas and Brazil. Linnaeus took the species name from Hermann Boerhaave who had created *Pavia* as a genus in 1720. Linnaeus had not only seen the Plukenet plate, he had also studied live plants at the *Hortus Cliffortianus*.

Thus, the first record of *A. pavia* in Europe noted that it had been used as a fish poison. Steyermark (1963), Uphof (1968), and Hocking (1997) also noted that the powdered seeds and crushed branches have been used to catch fish. Although no mention is made of that use for this species, Moerman (1998) does note the application by indigenous people for both *A. glabra* and *A. californica*. The roots contain a mixture of saponins called aescin, which have been used for soap (Steyermark 1963, Foster and Duke 1990), and those chemicals are surely why buckeyes are effective in killing fish.

Relatively few uses are recorded for *A. pavia* among indigenous people. The Cherokee made a poultice of the nuts for tumors and sores, and used a preparation to relieve colic and dyspepsia (Hamel and Chiltoskey 1975). They mixed scarlet buckeye with other plants used during childbirth to stop bleeding afterward, for swellings and sprains, and to prevent fainting (Hamel and Chiltoskey 1975).

Apparently, indigenous Americans also started the belief still prevalent in whites and blacks that carrying the seeds would help rheumatism, bring good luck, and relieve piles (Hamel and Chiltoskey 1975). Seeds from any species are considered equally effective in achieving those results (Moerman 1998).

Foster and Duke (1990) suggest that applications of all *Aesculus* in the Americas are essentially equal. Thus, the Delaware used *A. glabra* to treat earache, and the Iroquois and Mohegan used *A. hippocastanum* to relieve chest pains (Moerman 1998).

Scarlet buckeye is so small that its wood would probably not have been used as was yellow buckeye, *A. flava*. The Cherokee at least used wood of that related species for lumber, to make baby cradles, and in masks and dough trays (Hamel and Chiltoskey 1975).

Early colonists learned to be wary of the New World species because they were more toxic than the Old World plant (Millsbaugh 1892). Still, the active chemicals are not systematically absorbed, and they continue to be used outside the United States to reduce swelling and seal capillaries (Foster and Duke 1990). All of the species irritate the mucous membranes, causing upset stomach if taken internally, but no fatalities have been recorded in the United States (Foster and Duke 1990).

### *Agalinis*

(From Greek *aga*, wonder, and Latin *linum*, flax, because C.F.Rafinesque, 1783–1840, thought some species superficially resembled flax)

*Agalinis tenuifolia* (narrow-leaved)  
kidney weed

slender [slender-leaved] gerardia (*Gerardeia*, formerly a genus name, commemorating the celebrated herbalist John Gerarde, 1545–1611)  
 slender-leaf false foxglove [slenderleaf false foxglove] (“foxglove” compares this herb with *Digitalis*)

*Agalinis* is an American genus with about 40 species (Mabberley 1997). It was defined previously as containing more species, but those species have since been placed in other genera.

The Meskwaki of Iowa used an infusion to treat diarrhea (King 1984). Morton (1974) found the people of South Carolina using the old stems as a diuretic. They also used the tea as a “nice drink anytime.” Hocking (1997) considered the plant toxic to livestock.

### *Agave*

(Greek *agavos*, meaning admirable, noble, splendid)

*a'ud* [*a'od*] (Akimel O'odham, Hai-ced O'odham, Tohono O'odham, Arizona, Sonora)

American aloes (Europeans)

bamboo (Bahamas)

*bitoba* [*toba*] (Zapotec, Oaxaca)

cactus (Americans)

century plant (Americans)

*haamxö* (Seri, Sonora)

*maguey* (from Taino, Spanish)

*metl* (Náhuatl, Mexico)

*nootah* (Navajo, New Mexico)

*Agave decipiens* (ensnare or deceive)

*pasalátkicó:bí* (big yucca, Mikasuki)

false sisal (Florida)

*Agave neglecta* (neglected, overlooked)

wild century plant (Florida)

Most English-speaking Americans call these spiny, drought-resistant, succulent herbs either “century plant” or “cactus.” Europeans call the genus “American aloes.” Bahamians say “bamboo.” Indeed, none of these terms is biologically correct. The plants do not take a century to flower (10 to ~50 years, depending on the species), nor are they a “cactus” except in the original meaning of the word—“spiny” or “prickly.” Because the Europeans were familiar with aloes (*Aloe*), they compared the American plants to them—they are not only similar in appearance, but both also provide medicines. Why Bahamians call them “bamboo” is a curiosity. To me there is no resemblance.

The heartland of the agaves is Mexico, where they are famous for producing intoxicating beverages called *tequila*, *mescal*, and *pulque* (De Barrios 1971, Hutson and

Marshall 1995). In addition, the plants were formerly a more important source of food, fibers that were used for clothing, ropes, and rigging for sailing ships, paper, soap, and medicines. These plants were “the corner grocery” for inhabitants of pre-European Mexico (Standley 1920–1926, Morton 1968b, 1981, Gentry 1982). Strangely, there were two native species in Florida—*Agave decipiens* and *A. neglecta*. The only non-European name we have for either of these prickly plants is from the Mikasuki—*pasalâtikicó: bí* (big yucca). These people, originally from southern Georgia and the vicinity, were familiar with *Yucca aloifolia* that grew along the coasts in that area and farther north into the Carolinas and west into Mississippi (Sturtevant 1955). Since the Mikasuki speakers were relatively late arrivals in central and southern Florida, we have little idea of what the earlier inhabitants may have called the plants or how they used them.

Both of Florida’s *Agave* have been anomalies since they were discovered and described. *Agave decipiens* was named in 1892 by the keeper of the herbarium at Kew, John Gilbert Baker (1834–1920). Although *A. neglecta* was officially named in 1903 by John Kunkle Small (1869–1938), the plants had been recorded (misidentified as *A. vivipera*) at the Cape Canaveral area of Florida by William Bartram after he lived there in December 1766. Indeed, Small named the species based on a Bartram drawing (Harper 1958) and cultivated material sent to him from Eustis (Lake County).

There are no species native to the area between Texas and southern Florida where the *Agave* are found. Moreover, *A. decipiens* belongs with what the late *Agave* guru Howard Scott Gentry (1982) called group *Rigidae*, and its nearest relatives are Mexican. Similarly, *A. neglecta* is in group *Sisalanae*, also Mexican. The nine species native to the Bahamas, and those in the other Caribbean islands, are more distantly allied to the Florida plants. Moerman (1998) reported the Apache using *A. decipiens*, but it does not occur in their range.

One of *A. decipiens*’ probable closest relatives is *A. angustifolia*, itself famous for being the most widespread species in the genus. The Mexican *A. angustifolia* has been cultivated by perhaps every indigenous group in the New World from northwestern Sonora and northern Tamaulipas south to Costa Rica. Because of this cultivation, and the incredible array of habitats in which the plants grow, from sea level to 1500 m, there is a vast morphological spectrum in traits (Colunga-García Marin et al. 1996, 1997, 1999). Also related are *A. fourcroydes*, famous for fiber production (called *henequén* in Spanish, although originally Taino), and *A. tequilana*, from which the alcoholic beverage is obtained. Surely, with relatives like these, the Florida *A. decipiens* had similar uses among the indigenous people.

Perhaps the nearest relative of *A. neglecta* is *A. weberi* of the arid Mexican highland or the horticultural *A. desmettiana*, which is disturbingly variable. All three are related to *A. sisalana*. That Mexican species, the source of *sisal* fibers, was introduced into Florida in the 1800s by physician Henry Perrine (1797–1840). Perrine actually gave the species its scientific name before his untimely demise on Key Biscayne during a Seminole raid. Florida native *A. decipiens* is sometimes called “false sisal” to distinguish it from the cultivated Mexican introduction. *Agave neglecta* is so rare that no one knows much about it, and the species should be considered endangered.

The most widespread common name for *Agave* among Spanish-speaking Americans is *maguey*. This is the name usually encountered in Mexico, although it is a Taino word from Haiti. *Maguey* originally probably referred to the *Agave* look-alike, *Furcraea*, and it

appeared in the literature by 1555. That original source (Eden 1555 in OED 1971) said, “*palmarum puta Maguieorum, que est herba*” (of the palm called Maguey, which is an herb).” Richard Eden went on to compare the plants to European orpine (*Sedum telephium*, Crassulaceae) because both have fleshy leaves. That may have been the earliest commentary on convergent evolution in print.

By 1745, in his book *A true and impartial journal of a voyage to the South-Seas and round the globe*, Englishman Pascoe Thomas wrote: “They call it a Maguey tree, and from it they get Wine, Vinegar, Honey, Thread, Needles, Stuffs for clothing, or Sails for Canoes and small Boats, and timber for building.” Before him, the first three people who mentioned the plants made their first reference to the “wine” it produced.

By the time Linnaeus got around to naming the genus *Agave*, he decided to use a word that had been important to the Greeks—*agavos*, admirable, noble, splendid. Doubtless, he also had in mind the Greek mythological person Agave, who was a daughter of Cadmus and Harmonia (Quattrocchi 2000). Surely, Linnaeus intended the classical Old World name for New World plants to emphasize the important roles they played in the lives of the American natives.

While the Caribbean word overshadowed the Mexican name for the plants, many in that country still have names for the plants in their own languages. The Aztecs called the genus *metl*. Moreover, they continue to use a binomial nomenclature that predated that “innovation” by European scientist Linnaeus. Gentry recorded species in Mexico called *metometl* (worm agave), *pizometl* (small agave), and *papalometl* (talkative agave).

People living north of the Aztecs, but still speaking related Uto-Aztecan languages, called agaves by very different names. Three of these groups lived in Arizona (Akimel O’odham, Hai-ced O’odham, Tohono O’odham), and they say the plants are *a’ud* or *a’od*. The Seri, who also speak a related language, sometimes use the name *haamxö* as a generic for *Agave*. However, they also have names for each kind, such as *hamoc* or *coptoj* (different varieties of *A. angustifolia*), and *xica istj catitic* (soft-leaved thing) for *A. cerulata*.

Huastec Mayan speakers who live in the states of Veracruz and San Luis Potosí call different species *weey*, *witch*, and *tsi’lim*. The Zapotec who live south of the Aztecs in Oaxaca and vicinity have a “generic” *Agave* name—*bitoba*, sometimes shortened to *toba*.

The genus *Agave* is a virtual chemical cauldron at different stages of its life. Perhaps the most important stage to it and people is just before it flowers. At that time the plant has stored up many carbohydrates to fuel the last phase of its life since the plants are monocarpic, flower once, and then die. People throughout the range of the genus used this time to either harvest the stem (the *piña*, because it resembles a pineapple after the leaves are removed), roast it, and consume the sugar-rich products, or they tapped the budding flower stalk and drained off the juices (*aguamiel*, honey water in Spanish). Once this *aguamiel* had fermented, it became *pulque*. The plants from which this was taken were associated with deities; the principal one was *Mayahuel*, the Aztec goddess of *pulque*.

If the plants were harvested just before the flower stalk began growing, they could then be roasted in pits to produce a sugar-rich food. This was done by cutting off the leaves from the *piña* or *cabeza* for roasting. The cooked product was called *mescal* (from *mexcali*, Náhuatl). This process was developed to the point that certain Mexican cultures, and those in what is now Arizona and New Mexico, depended on *Agave* for food during

certain times of the year. We even have the practice “immortalized” in the Athabascan group called the “Mescalero Apaches.” Other people in the southwestern United States also depended on this food source, but those called Mescalero Apaches were formerly a particularly warlike group. Only in the years since about 1990 have we learned how important this *Agave* food also was to the people who originally lived in the valley of Phoenix, Arizona and nearby (Dobyns 1988, Adams and Adams 1998).

Leaves were taken from the plants, roasted, and used by the Aztecs to produce paper, especially the leaves of the apical growing part of the plants. Other plants served as paper sources more often (cf. *Ficus*: Strangler fig), but there are still extant early post-Columbian manuscripts on paper made of agave fibers.

Distilled alcoholic beverages were unknown to the natives of the Americas before the Europeans arrived. However, indigenous Americans soon adopted distillation and began producing the Mexican equivalent of U.S. “moonshine.” Until recently, these were comparatively small operations, but now large companies have begun producing quality beverages. Some of these companies with a reputation for fine products are Cuervo, Sauza, and Robert Denton.

Leaves contain sapogenins, sterols, terpenes and vitamins (Dewidar and el-Munajjed 1970, Blunden et al. 1974, 1980, 1986, Kintja et al. 1975, Cripps and Blunden 1978, Reichelt and Stransky 1978, Bedour et al. 1979, Xu and Zhou 1982, Sati et al. 1985, Camp et al. 1988, Ding et al. 1993, Yokosuka et al. 2000, Abdel-Khalik et al. 2002, da Silva et al. 2002). However, all the compounds that cause dermatitis are not known. Nor do we know what the pain-causing exudate is on the spines, but recently calcium oxalate raphides have been implicated (Salinas et al. 2001). Many people use the leaves as poultices for itch, sores, bruises, and wounds. Some also use them as a source of fish poisons, and one Mexican species (*A. lechuguilla*) has been used to poison arrows (Gentry 1982). A by-product of fiber operations in Mexico and East Africa is an extract that is pivotal in the manufacture of steroid drugs, including cortisone and birth control pills. Laboratory evidence supports many of the uses (Bianchi and Cole 1969, Davidson and Ortiz de Montellano 1983, Segura et al. 1991, Uniyal et al. 1991, Verastegui et al. 1996, Peana et al. 1997, Garcia et al. 2000). The chemistry of the plants is so impressive that even cultures where they are not native have incorporated them into medical practices (Duncan et al. 1999, Kassu et al. 1999).

“There is good and evil in everything,” goes an old adage. The rise of popularity of *Agave* products that parallels the population growth in Mexico and the United States has its downside. In some areas, *Agaves* are thought to be overharvested (Burwell 1995). In other regions, those that remain after harvests from the wild are not producing fruits. That lack of reproduction is said by some to be directly related to the decline in pollinators, including nectar-feeding bats and hummingbirds (Arizaga et al. 2000a,b, Slauson 2000). So, the next time you drink a toast with an *Agave* product, remember to thank the bats and birds that made it possible!

*Ageratina*

(A diminutive form of the genus *Ageratum*, from Greek *ageraton*, not growing old, an allusion to the long-lasting flowers; perhaps originally applied by Pliny, A.D. 23–79, to what is now *Achillea*)

*Ageratina altissima* (tallest) (= *Eupatorium ageratoides*, *Eupatorium rugosum*)

deerwort-boneset (“boneset,” a name applied by 1670 to comfrey, *Symphytum officinale*; applied to these American plants later)

hemp-agrimony (comparing it with *Agrimonia*, which see)

milk-sickness plant (from the technical physician’s name *morbeo lacteo*)

*noota ikheesh* (*noti’*, tooth, *ikhsnsh*, medicine, Choctaw, Chickasaw)

richweed

[Indian, white] sanicle (comparing it with *Sanicula*, which see)

squaw-weed (North Carolina)

stevia (after the genus *Stevia*?, Wisconsin)

thoroughwort

white snakeroot (one of many plants used by indigenous people to treat snakebite) white-top

*Ageratina* is a genus of perhaps 290 species in the eastern United States, Central America, and western South America (Mabberley 1997). Although the French botanist Édouard Spach (1801–1879) named the genus in 1841, the species have been mostly placed in *Eupatorium* until recently. Robert M. King and Harold Robinson emphasized the distinctiveness of *Ageratina* from *Eupatorium* in 1970, and most have accepted the two since then.

The Cherokee used the herb to treat ague (from Latin *acutus*, acute; malaria, see Desowitz 1991), diarrhea, fever, kidney stones, and urinary diseases, and as a diuretic, stimulant, and tonic (Hamel and Chiltoskey 1975). The Chickasaw chewed the root or held it in the mouth to stop toothache (Campbell 1951). The Choctaw used it against toothache like the Chickasaw, and also as a stimulant and tonic (Campbell 1951). The Iroquois used the herb to treat venereal disease, as a physic, in sweat baths, and to treat a prolapsed or inflamed womb. The Meskwaki also used it in steam baths and to revive an unconscious patient (Moerman 1998). The Shawnee used it to treat snakebite (Coffey 1993).

*Morbeo lacteo* (milk sickness), also called the “trembles,” was a mysterious and feared disease that attacked farm families and their livestock in the 1800s (Coffey 1993). The malady was more common in the South and Midwest, particularly in North Carolina, Ohio, Indiana, and Illinois. In 1818, Abraham Lincoln’s mother, Nancy Hanks Lincoln, died of this disease in Little Pigeon Creek, Indiana. At least partly because of that, Thomas Lincoln and his new wife Sarah and young Abraham moved to Illinois. Although the cause of the problem was determined in the 1830s, county officials in Kentucky complained in 1852 that the disease was so prevalent that it deterred settlers.

It was a Shawnee woman who showed Illinois physician Anna Pierce the poisonous plant causing the disease (Coffey 1993). That fugitive from the forced relocations of local tribes, known only as Aunt Shawnee, explained the relationship between the white snakeroot and both milk sickness and trembles. However, it was not until 1917 that physicians were convinced that the plant caused the problems.

Tremetol, a toxic alcohol, is the chemical causing “milk-sick,” or milk sickness in humans or trembling in other animals. The plant causes ketosis (excess ketone bodies; overly acidic body chemistry) and is transmitted through cow’s milk to people. The breath takes on a fruity odor as acetone diffuses from the lungs. The symptoms are progressive and include lassitude, nausea, vomiting, stomach pains, intense thirst, prostration, coma, and death.

Later people considered the roots diuretic, diaphoretic, antispasmodic, aromatic, and vulnerary (Millspaugh 1892, Hocking 1997).

### *Ageratum*

(From Greek *ageraton*, not growing old, an allusion to the long-lasting flowers; a name probably first applied by Pliny, A.D. 23–79, to *Achillea ageraton*)

*Ageratum littorale* (of sea coasts)

Cape Sable whiteweed

*hauayche* (*hauay*, expanded, *che’*, *plant*, Maya, Yucatán)

*tup-lan-xix* (*tup*, extinguish fire, *lan*, immerse, *xix*, excess, Maya, Belize; see also *Melanthera*)

*Ageratum* was named by Linnaeus in 1753, based on plants he knew from the Americas. Subsequently, discoveries have expanded the genus to 44 tropical American species. The rarest of these, at least in Florida, is *A. littorale*. The species was first described as part of the genus *Coelestina* by physician John Torrey (1796–1873) and Harvard professor Asa Gray (1810–1888) in 1841 from a specimen collected in Key West. Then, Gray realized that it was best put in *Ageratum*, and he made the change to *A. littorale* in 1881. These plants are so rare they are considered endangered in Florida (Coile 2000).

Martínez (1969) recorded the Mayan name in Yucatán, and said that the plant was used to treat *culebrilla* (ringworm). Balick et al. (2000) indicated that it was also considered medicinal in Belize but gave no details. The herb grows in Key West, Quintana Roo, Belize, Honduras, and Guatemala.

### *Agrimonia*

(A plant mentioned by Pliny, A.D. 23–79, usually considered to be a corruption of *Argemone*)

***Agrimonia*.** *Agrimonia microcarpa* .  
*Agrimonia rostellata* . Both from  
 Britton and Brown 1987.

agrimony [agrimonie, egremoine, egremounde, ergrimonie] (English, variant spelling from 1578–1597); *agrimonia* (Italian); *agrimonia* (Spanish from 1557); *aigremoine* (French from 1550); *Odermenig* (German pronunciation of “agrimony,” from 1542)

*Bruchwurtz* (fracture herb, German from 1542)

*eupatorio* (Italian from 1551; from *Eupatorium*, which see)

*geurach* (sharp, Gaelic)

*mirean* (Gaelic)

*muir dhroighinn* (*muir*, sea, *dhroighinn*, bramble, Gaelic)

***Agrimonia incisa*** (cut into, alluding to the compound leaves)  
 incised agrimony

***Agrimonia microcarpa*** (small-fruited)  
 slender groovebur  
 small-fruit agrimony

***Agrimonia rostellata*** (with a small beak)  
 woodland agrimony [groovebur]

A single species of agrimony was well known to Europeans by the time they reached the New World. Linnaeus gave it the modern name of *A. eupatoria* in 1753. The common names listed under the genus were current from the time of Leonard Fuchs.

That Old World species was also known as church steeples, cocklebur, philanthropos, and stickwort, and was considered a panacea through the ages from the classical Greek and Roman times to the late 19th century (Dobelis 1986). The ancient Greeks used the plant to treat eye problems, diarrhea, gall bladder, liver and kidney ailments; Anglo-Saxons extended it to treat wounds, and in the 1800s it was prescribed for skin diseases, asthma, coughs, sore throat, and gynecological complaints (Dobelis 1986).

No records have been found of the Florida species that were used. However, it is known that the Cherokee, Iroquois, Meskwaki, Ojibwa, and Potawatomi used native

American species (Smith 1933, Moerman 1998). Since these American species were used in many of the same ways as the Old World *A. eupatoria*, it seems likely that they contain many of the same compounds.

### *Aletris*

(From Greek *altho*, *aleo*, to grind; Aletris was a legendary female slave who ground grain; apparently, it was the mealy texture on the outside of the corolla that caught Linnaeus's attention and led him to use this name)

#### *Aletris aurea* (golden)

golden colic-root [golden colicroot]

#### *Aletris farinosa* (mealy)

ague grass [root] (used to treat ague or malaria)

*aletris* (Brazil); *alétris farineux* (mealy aletris, French); *mehlige*

*Aletris* (mealy aletris, German)

aloe [star] root [wort]; [yellow] star-grass (North Carolina in 1737)

bitter grass; bettie grass; bitter plant

***Aletris*.** a–c. *Aletris aurea*. a. Habit, b. Flower, c. Capsule, d–g. *Aletris farinosa*. d. Upper part of plant, e. Flower, f. Corolla split longitudinally, g. Capsule. Drawn by Vivian Frazier. From Correll and Correll 1972.

black root (usually *Pterocaulon pycnostachyum*)  
 blazing star (usually applied to *Liatris* spp.)  
*cadenaco* (horn plant, Brazil)  
 colic [cole] root (to treat colic); *raiz das cólicas* (colic root, Brazil);  
 yellow colic root  
*cometo-orinito* (urine maker, Brazil)  
 crow corn  
 Devil's bit (usually applied to *Chamaelirium luteum*)  
*erva-da-febres* (fever herb, Brazil); *erva-estrela* (star herb, Brazil)  
 [false] unicorn [plant, root]  
*wá'sa wi'ti* (cane medicine, Catawba); [*wá' sahawane*] (cane leaves, Catawba)  
*wisakon* [*wissakan*] (it is bitter, Powhatan, Virginia; Capt. John Smith on Roanoke Island, North Carolina, in 1585 wrote: "the herbe which the savages call *Wysauke* werewith they cure their wounds which they receive by the poisoned arrows of their enemies"; Strachey wrote of *wighsacan* in 1612, "a small root which they bruise and apply to wounds...so this cureth their hurts" and "taken for purgative in spring"); cognates include *wéʔsakan* (Menomini); *wiʔða-kanwi* (Shawnee); *wisakan* (Cree)

Some of the early physicians and botanists who came to the eastern coastal regions of America found indigenous people using *Aletris* to combat colic and dysentery. As both of those were common problems at the time, a remedy was important. At first, it was thought that only one species was effective. However, now it is known that most, if not all, of the American species have the same medical attributes (Millsbaugh 1892, Ellingwood and Lloyd 1898, Lewis and Elvin-Lewis 1977).

The first record after the failed colonization attempt on Roanoke Island by Sir Walter Raleigh seems to have been by John Brickell. This resident of North Carolina wrote in 1737 that "stargrass" was "used with good Success in most Fevers in this Country." About the same time, John Bartram wrote European physician Cadwallader Colden that "ye star root is chiefly used by several for ye pain of ye stomach thay boil ye root in water & drink ye decoction after ye method of our Indians from whom they learned ye use of it" (Vogel 1970). Both Brickell and Bartram had the Catawba as their sources.

Rafinesque, who also worked in the same region during the 1820s, wrote that *Aletris* was used by country physicians and Indian doctors and was highly valued by them for its tonic and stomachic properties. Some even considered it slightly narcotic. The same view was echoed by Dr. Jacob Bigelow in *American Medicinal Botany*, published between 1817 and 1820. Although several uses were attributed to the plants, most considered them tonic and best used against stomach problems, especially colic (Millsbaugh 1892, Vogel 1970). Hocking (1997) still considered *A. aurea* tonic. In spite of this reputation, Yanovsky (1936) said the "bitter bulbs" were eaten in Louisiana.

By the 1930s, studies among the Catawba recorded that they still used the plants by soaking the leaves in water to produce an antidiarrheal tea, and the root for any type of colic or stomach problem (Speck 1937, 1944). Although some sources say that the roots are a remedy, especially against colic in infants, careful reading of the literature of the 1800s and before suggests that digestive upsets in adults as well as infants were termed

“colic.” By the mid-1950s, it was known that *Aletris* roots contained saponin and a bitter principle. At that time, the genus was still being used as a digestive aid, but also as a “uterine tonic” and a diuretic. The diuretic properties made the genus useful against dropsy (congestive heart problems). Since the roots are laxative, they were used against that—although they were also used to treat diarrhea. Some have also recommended the medicine for coughs and colds (Ellingwood and Lloyd 1898, Morton 1974).

For some time the use and properties of *Aletris* fell out of popularity. This may well have been caused by Harvey Wickes Felter, M.D. In 1922, Felter, in his version of *The Eclectic Materia Medica*, proclaimed that all the attributes touted for *Aletris* were because of confusion with *Chamaelirium* (Felter 1922). He went further to say that *Aletris* was worthless and should not be considered medicinal. Many subsequent books on medical plants have done what the authors of *World Economic Plants* did in 1999 (Wiersema and León 1999). Under the heading “ALETRIS” they wrote “Medic. (folklore).” If it is *just* folklore, then people are making millions of dollars in the current herbal remedy industry selling the roots of U.S. *Aletris*.

### *Allium*

(Classical Latin name for garlic, *Allium sativum*, it has been suggested that the name is based on the Celtic word *all*, pungent, cf. Kindscher 1987; that word does not occur in Dwelly’s 1933 Gaelic dictionary, but *alla* means fierce, wild, which may be the same)

*aglio* (from *allium*, Italian); *ail* (French); *ajo* (Spanish); *ajuin* (Dutch); *alho* (Portuguese)

*ahkohtew`vslpse* (Plains Cree)

*cacomite* (from *cacomitl*, Náhuatl, Mexico)

garlic (a compound word derived from Old English *gárléac*, containing *gár*, a spear or javelin, *léac*, leek, the culinary herb; used in English by ca. A.D. 1000); *geirlauk-r* (Old Norse); *gairleag* (Gaelic)

*hato\_falaha* [*hatoŋ\_falaha*] (*hato*, winter, *falaha*, onion, Choctaw)

*hvitløk* (*hvit*, white, *løk*, onion, Norwegian)

*Knoblauch* (German); *knobloch* (Dutch)

*kosáoma* [*kosooma*] (an onion or garlic, but also something that stinks, Alabama)

*onochschà* (Onondaga)

*schordon* (Greek)

*shumim* (Hebrew); *sumu* (Akkadian)

*svgi* (Cherokee)

*tôm* (Arabic)

*uleepen* (Delaware)

*winúnschi* (Delaware)

*Allium canadense* (of Canada)

*ail du Canada* (Canada garlic, Quebec)

*anwan`fka* (Ofo)

***Allium canadense*.** From Institute of Food and Agricultural Sciences.

*cîgaga 'wûn* (skunk plant, Potawatomi); *jigâgamanj* (Ojibwa)  
*hashtola' atofalla'a* (*hashtola'*, winter, *atofalla'a'*, onion, Chickasaw);  
*kosâoma hissi okchâkkoya ilpa* [*kosâoma hissi okchâkkoya*] (*kosâoma*, onion, *hissi*, hair, *okchakko*, blue-green, *ilpa*, eat, Alabama)  
*kha-a'-mot-ot-ke'wat* (skunk testes, Cheyenne); *kha-ohk-tsi-me-is'tse-hi* (skunk, it smells, Cheyenne)  
 meadow [wild] garlic  
*mon-zhon-xe* [*mon-zonxe*] (*mon-zhon*, earth, *waxe*, to bury; akin to *mon-shon'-dse*, a hole in the ground, Osage)  
*psin* (Lakota)  
*tafvmppe vhake* [*ta-fvm'pe*, *tafv'mp-hâke*] (*fvmpe*, stink, *vhake*, resembling, Muskogee); *tafvmpuce* (*fvmpe*, stink, *oce*, little, Muskogee)  
*towâ bosôhka* (*towâ*, onion, *bosôhka*, bad smelling, Koasati)  
*ûñktcinsayi* (Biloxi)

wild onion (“onion” from Latin *union*, a rustic Roman name for a single onion bulb, otherwise a pearl)

Members of the genus *Allium* were so important to Old World people that each language had a name for each of the species. In English, for example, there are chives (*A. schoenoprasum*), garlic (*A. sativum*), leeks (*A. porrum*), onions (*A. cepa*), ramsons (*A. ursinum*), scallions (*A. cepa*), and shallots (*A. ascalonicum*). A similar list could be made in the Romance and other Germanic languages. Gaelic, the most distinct of the western European languages, called them *saidse* (chives), *gairleag* (garlic), *leigis* (leeks), *uinnean* (onion), *gairgean* (ramsons), and *siobaid* (scallions). If they have a name for shallots, it has not been located.

In 1674, the Franciscan priest Jacques Marquette and his party traveled from Green Bay to the present site of Chicago eating almost nothing but *A. canadense* and *A. tricoccum* (Hedrick 1919, Fernald et al. 1958). The name of the city Chicago is corrupted from the Menomini name *shika'ko* (skunk place) because of the quantity of onions there and their dependence on them. Steyermark (1963) wrote that the bulbs “have a rather sweet flavor and are edible, while the bulblets of the inflorescence can be pickled and eaten as such.” He further recorded that the entire plant, before flowering, can be boiled and made into soup and that the young fresh leaves were used in salads or as a garnish for flavoring meats, cheese, and other dishes.

Prehistoric people used onions, probably also as food. Gilmore (1931) found bulbs in the Ozark Bluff-Dweller site in Arkansas. Historic people from New England (Iroquois), Wisconsin (Menomini, Potawatomi, Winnebago), the Dakotas (Lakota), Nebraska (Omaha, Pawnee, Ponca), Iowa (Meskwaki), Illinois (Sauk-Fox), and the Carolinas (Cherokee) used these onions. These people ate them in soups, dried the bulbs for seasoning, and used them fresh as a relish (Smith 1933, Yanovsky 1936, Moerman 1998). Related species were similarly used. Oddly, no records seem to exist of southeastern people using the plants, but at least the Alabama, Chickasaw, and Muskogee have names for them. Maybe they were like the Powhatan, of whom Strachey ([1612] 1953) said, “the Inhabitans cannot abyde to eate of them.” Moerman (1998) said the species was used by the Mahuna (California), but Hickman (1993) does not list the species.

In spite of this wide usage, it is said that in large quantity wild onion has killed cattle, and gastroenteritis has been reported in children (Lampe and McCann 1985, Diggs et al. 1999).

### *Alnus*

(From the classical Latin name for the alder; Akkadian *alanu*, oak, acorn)

***Alnus serrulata*.** a. Branch with pistillate aments. b. Branch with staminate aments. c. Young staminate aments. d. Staminate ament. e. Pistillate ament. f. Bract of pistillate ament. g. Bracts and nutlets. h. Nutlet. Drawn by Vivian Frazier. From Correll and Correll 1972.

alder (from Old English *alor*, *aler*, in use since ca. A.D. 700, related to Old Norse *elrir*, Old High German *elira*, *eirla*, and modern German *Erie*, *Eller*); aller (by Turner [1548] 1965; he wrote: “*Alnus* is called in greke Clethra, in Englishe an alder tree or an aller tree, in duche erlinbaum”); cognates include *aile* [*ilite*] (Spanish); *aune* [*aulne*] (French); *erlin* [*els*, *elst*, *elzenboom*] (Dutch)

*atob* (bitter, Potawatomi); *tópi* (*takw*, healing, *pi*, material, Delaware); *wadôb* (Ojibwa)

*fèarn* (Gaelic; fourth letter in the old *Ogham* alphabet)

*gatogèhha* (Onondaga)

*okowwaykací* (*okí*, water, *wáyka*, hanging over the edge, Koasati)

*ontano* (Italian)

*uhl* (Swedish)

*verne* (French)

*wa’p?tu* (Catawba); *yap si-wi saka’re* (red blossom tree, Catawba)

***Alnus serrulata*** (saw-toothed, in reference to the leaf margins)

alder [American, common, green, hazel, red, smooth, speckled, tag]

The enthusiastic and energetic British gardener Philip Miller (1691–1771) created the genus *Alnus* in the fourth edition of his *The Gardeners Dictionary* in 1754. Although this book went through four subsequent editions, his rendition of the Roman name for the alder tree stuck (de Cleene and Lejeune 2002). As exploration of the New World

continued, Royal Gardener at Kew William Townsend Aiton (1731–1793) described plants from Pennsylvania as *Betula serrulata* in 1789. It took the director of the Berlin Botanical Garden, Carl Ludwig Willdenow, to realize that these were really *Alnus* and to create the modern name in 1805.

Moerman (1998) lists most of the American species of *Alnus* as having been used by indigenous people. In the southeastern United States, *A. serrulata* is recorded as used by only the Cherokee (Hamel and Chiltoskey 1975) as an analgesic, as a blood tonic, to treat coughs and skin and kidney problems, and as an emetic and purgative. The virtues of the plant were taught to the whites, and Porcher (1863) praised it highly for treating skin problems and internal or external bleeding. The bark contains tannic acid, which was formerly used in treatment of intermittent fever, as an alterative and astringent (Vines 1977, King 1984).

### *Alternanthera*

(Latin *alternus*, to change or alter; and *anthera*, anther; the stamens alternate between fertile and sterile)

#### *Alternanthera flavescens* (yellowish)

*alegría* (happiness, Spanish)

*amor seco del monte* (wild dry love, Mexico)

chaff-flower (“chaff” is an old Teutonic-based word for the husks left from thrashing grain; the word was derived from Old English *ceaf*, which is cognate with Dutch *kaf*; “chaff” was in English by ca. A.D. 1000; “chaff-weed” was applied by Turner [1548] 1965 to a *Gnaphalium*, and the word “flower” was combined later for members of the Amaranthaceae)

immortelle (brought into English from French *fleur immortelle* by 1832; meaning “live-forever”)

*jiquilete* (*xiuitl*, herb, *quilitl*, edible herb, Náhuatl, Mexico)

joy weed (maybe simply a translation of *alegría*)

live-forever (in use by Gerarde’s *Herball* of 1597 for a number of plants with long lives)

*perpétua* (perpetual or live-forever, Spanish); *perpétua-da-mata* (live-forever of the forest [wild], Brazil)

straw-flower (“straw” is from Old English *stréaw*, from a Teutonic origin with cognates *stroo* in Dutch, *Stroh* in German, *strå* in Swedish, and *straa* in Danish; by ca. A.D. 1000, it meant specifically the stalks of grasses, but subsequently has been applied to dried stems of many plants)

*zac-muul* [*sac-muul*] (*sak*, white, *muul*, sandbur, Maya, Yucatán)

#### *Alternanthera maritima* (by the sea)

beach alternanthera

seaside joy weed

When the Spanish *conquistadores* entered what is now Mexico City, they found storehouses of seeds in Moctezuma's granaries. The Aztecs called the seeds *tzoalli*, and showed the Spaniards the fields of red-topped plants they came from. When the Europeans discovered the importance of the seeds in indigenous religions, they declared it a crime to grow them.

To the Aztecs, the red of these plants was a symbol of immortality. Although the Spanish were horrified by the celebrations using *tzoalli*, they understood the symbolism. Red for them too was the color of royalty. In southern Europe, the plants became *alegría* (happiness or joy) or *perpétua* (perpetual or live-forever). Immortelle became a common name in English, although it was originally used for another plant in an entirely different family (*Xeranthemum*, Asteraceae).

The seeds called *tzoalli* were *Amaranthus* (which see for details). Yet, in local usage, the common name *perpétua* or "live-forever" came to be applied to one of its relatives. The related genus is *Alternanthera*, and it was named by Linnaeus's Danish student Pehr Forsskål (1732–1763). However, his *Flora aegyptiacoarabico* did not appear until 1775, after he had died of exposure in the deserts of the Arabian Peninsula. There now are about 200 species in the genus, most of which are scattered throughout tropical America (Mabberley 1997).

The species most commonly seen in Florida is *A. flavescens*, long known as *A. ramosissima*. This herb is called by several names in various parts of its range. In English, the plants are known as "chaff-flower" or "straw-flower," because of the papery scales between the small, almost insignificant flowers. They are also called "live-forever," an allusion to, or perhaps even a translation of the Spanish *perpétua*. In Brazilian Portuguese, this became *perpétua-da-mata* (wild live-forever) to distinguish them from those people cultivate (simply *perpétua*).

Those species for which we have recorded uses are largely applied to the same suite of problems (Morton 1981, Arvigo and Balick 1993, Mors et al. 2000). Decoctions of the plant are used to relieve coughs, or an infusion of the plant is considered sudorific. Internally, they are remedies for flu, colds, urinary problems, tiredness, and internal infections (especially of the reproductive organs), and they are used as a postpartum tonic. Externally, the juice of mashed or lightly cooked leaves is considered a good poultice for mouth sores, thrush, and to stop bleeding. Barbadians take a decoction to halt dysentery and as an abortifacient. One (*A. brasiliensis*), and perhaps others, is called "Evil eye bush," and is an herb cultivated as a remedy against that problem. In Guyana, the Warao boil some leaves in a half gallon of water for 15 minutes. Then they bathe children with the water twice a day from head to toe (Rinders 1993).

Some species are wide ranging. For example, *A. flavescens* extends from southern Florida, Jamaica, Hispaniola, Puerto Rico, Lesser Antilles to Trinidad, and southeastern Mexico to Belize and Brazil. The other native species in Florida, *A. maritima*, is found on beaches in southern Florida, the Bahamas, the Caribbean, and South America. It also occurs in western Africa, a pattern fairly common among ocean-dispersed plants (see also *Annona*). Although no specific uses for "beach alternanthera" were located, perhaps the widespread uses apply to it as in other species.

In Belize, *A. flavogrisea* is called *golondrina* [*colondrino*] (dove) by Spanish speakers, and *xix-canolol* (*xix*, bread crumbs, *ka'an*, yellow, *lol*, flower, so "yellow flower that looks like bread crumbs") in Maya. In the French Antilles, it is *herbe à albumine*

(albumin herb). The species has all of the uses listed earlier, and others that are not listed (Morton 1981, Fournet and Hammerton 1991).

*Alternanthera brasiliana* has been introduced into Florida, but it is native through much of the Caribbean and south into Brazil. It has common names including *caaponga* (Tupí for what is usually called in Portuguese *beldroega-pequena* or *Portulaca oleracea*), *ervaço* (usually applied to *grão de bico*, *Cicer arietinum*), *infalível* (infallable), *perpétua-da-mata* (wild live-forever), *perpétua-do-brasil* (live-forever of Brazil), *bouton blanc* (white button, French Antilles), and *herbacé par le haut* (herb for heat, French Antilles). In all the areas where it is native, *A. brasiliana* has medicinal uses, and the name *herbacé par le haut* suggests that it might have been used to treat fever or maybe even hot flashes.

*Alternanthera repens* occurs throughout Mexico and Central America, south to Peru and Argentina, and in western Africa. Names recorded for this species include *ardosa jardin* (ardent garden), broad path (rendered *herbe à bordure* in French Antilles), *cabalxtez* (prostrate plant that resembles a spiny bush, from *kabal*, prostrate plant, *x-tes*, spiny bush, Mayan), *caroca* (mistranscription of “carioca”?), *hierba de toro* (bull’s herb), *sacachiuquim* (*saca*, remove, *chiuquim*=?), *sanguinaria* (bloody, applied to rocks, plants, etc. with a red color), *tianguiz-pepétua* (store-[bought] live-forever), washer-woman, and *yerba del moro* (Moor’s herb). The species does not appear to be in the Caribbean, although older literature records it there.

One species in Brazil (*A. achyrantha*) has the intriguing name *erva-de-pinta*. Until the book by Desowitz entitled *Who Gave Pinta to the Santa Maria?*, most of us would not have known that *pinta* was a form of venereal disease. Brazilians use this herb to treat that and several other diseases (Mors et al. 2000). Indeed, several of the species in the genus are listed as being used to treat syphilis and other venereal diseases, but that typically is because they are diuretic and provide temporary relief from symptoms. Many plants in various parts of the world were (and probably still are) used to treat venereal diseases because, at least in part, they relieve symptoms. They do not alleviate the problem.

*Alternanthera sessilis* in the French Antilles is “rabbit meat,” which may mean it is used as food for domestic rabbits, to “make meat.” Or, it simply might mean that it was recognized as something that a rabbit might eat. This species is also called *maglwa* or *magloire* (my glory, my fame; a surname used by many in Dominica) in the French Antilles. In the Dominican Republic, the name *sanguinaria* is applied generically to several species of *Alternanthera*, but is used particularly for *A. sessilis*, also known as *santoma cimarrona* (wild Saint Thomas, or wild *Gomphrena globosa*). Both are used against urticaria and either cultivated or considered weeds in cultivated plots. Panamanians call it *sanguinaria* and eat the leaves as a famine food (Duke 1968). This same species in Taiwan is known as *han lien tsao*, and is substituted for *Eclipta prostrata* in herbal remedies to treat the liver and kidneys. Both are considered antibacterial, astringent, and anti-inflammatory (Hsu 1986). *Alternanthera pungens*, also medicinal, is called *yerba de pollo* (chicken herb) in the Dominican Republic.

Comparatively little has been found on the chemistry of *Alternanthera*. Some species contain coumarin analogues (Yang et al. 1989), flavonoids (Zhou et al. 1988), ionone derivatives (Ragasa et al. 2002), sterols (Patterson et al. 1991), and triterpene saponins (Sanoko et al. 1999). Laboratory studies suggest that some species are anticarcinogenic (Aruna and Sivaramakrishnan 1992), antidiarrheal (Zavala et al. 1998), antinociceptive,

at least in mice (Macedo et al. 1999), antiviral (Zhang et al. 1988, Unag et al. 1989, Qo et al. 1993), and hepatoprotective (Lin et al. 1994).

The most aberrant reference was for *A. lehmanii*, called *borrachera* or *chicha* in Colombia (Schultes and Raffauf 1990). According to them, this plant was occasionally added to *yagé* brews in Putumayo, Colombia, reputedly making a stronger beverage. A Web source (Gnostic Garden 2001) says, "Chemically obscure, needs further investigation." While that was intended for the species, it speaks for the whole genus.

### *Alvaradoa*

(Named after Pedro de Alvarado, companion of Cortés and conqueror of Guatemala and Salvador)

*Alvaradoa amorphoides*. a. Branch with staminate flowers, b. Leaf outline, c. Staminate flower, side view, d. Staminate flower, longitudinally dissected, e. Floral diagram of staminate flower, f. Branch with pistillate flowers, g. Pistillate flower, from the outside, h. Pistillate flower from the inside, i. Pistillate flower longitudinally dissected, j. Floral diagram of pistillate flower, k. Branch

with fruits. *Drawn by Priscilla Fawcett*. From Correll and Correll 1982.

***Alvaradoa amorphoides*** (resembling *Amorpha*)

- aretillo* (little earring, Sonora)
- aroma blanca* (white perfume, Cuba)
- bel-cini-chè* [*beezinik-ché*, *belsinik-ché*, *besinick-ché*, *besinik-ché*, and *xbesinik-ché*] (tree that is full of ants, Maya, Yucatán); *palo de hormigas* (ants' tree, Yucatán); *suetsinik-ché* (tree covered with ants, Maya, Yucatán)
- camarón* (shrimp, because of the flower/fruit color, Chiapas)
- charagallo* (gallo, rooster, Chiapas)
- cola [rabo] de ardilla* (squirrel tail, apparently in reference to the fruiting spikes, Mexico, Central America)
- cortacuero* (leather cutter, because of use in tanning, Belize)
- gavilán* (hawk)
- guaji* (Mayo, Sonora)
- guetzé-guetzé* [*gueguetzí*, *cuetzé*, *huezequi*] (Zoque, Chiapas)
- huichipil* [*huachipil*, *guacipil*] (maybe Náhuatl, Guerrero)
- ma'acita* (Guarijío, Sonora, Chihuahua)
- paenepa* (Mayo, Sonora)
- palo de sobo* (massage or kneading tree)
- palo torcido* (crooked wood, Sonora); *palo torsal* (twisted tree, Sonora)
- peinecillo* (little comb, Sonora)
- pié de gallo* (rooster foot, Sinaloa)
- plumajillo* (little feather, apparently in reference to the fruiting spikes, Guatemala)
- ruda cimarrona* (wild rue, notes a resemblance to *Ruta graveolens*, Quintana Roo)
- tamarandillo* (little tamarind, Cuba)
- tarajay* (resembling tamarisk, *Tamariscus*)
- wild Spanish armada (Cayman Islands)
- zo* (language unidentified, not Maya, Yucatan)

From 1762 to 1763, Frenchman Jean Baptiste Christophore Fuseé Aublet (1720–1778) explored French Guiana for the king of France. Aublet was not just a botanist, but also was trained as an apothecary's apprentice in Spain, had served in the medical branch of the army, helped prepare prescription drugs at the Charity Hospital in Paris, and worked as "Botanist and First Apothecary" of the Company of the Indies at *Ile de France* (Mauritius). He had just spent 9 years in Mauritius before he ventured to French Guiana at age 42. In the New World, he served as the king's apothecary-botanist.

In South America, Aublet worked with Caribs and Galibis, coastal tribes of Cariban stock who remain there today. In addition, he worked with people called Coursari, Garipon, Noirague, and Creole Negroes. Thus, his contacts spanned languages as distinct as Carib, Tupí, and Creole French. He described medical uses for many of the plants he

found, and he has been called the “founding father” of neotropical ethnobotany (Plotkin et al. 1991).

Among the 124 plants Aublet described from 56 different families was *Picramnia* (formerly Simaroubaceae, now Picramniaceae). Not surprisingly, several members of that family are effective medicinals, and Aublet described two of the most important genera—*Simaba* and *Simarouba*. Linnaeus had described *Quassia*, perhaps the most famous genus, while Aublet was still in French Guiana. *Quassia* and *Simaba* are used against fever, malaria, and dysentery (Hocking 1997).

Danish explorer Frederick Michael Liebmman (1813–1856), director of the botanical garden in Copenhagen, described *Alvaradoa*. The genus now contains five American species (Mabberley 1997).

In Yucatan, a decoction of *Alvaradoa* bark is drunk as a tonic for the digestive tract, and leaf decoctions are taken for urinary complaints (Morton 1981). Leaves mixed with honey and corn silk are used to stop bleeding. Leaves are put in warm baths for patients with rheumatism. The wood is strong and used in carpentry. Wood is also valued as fuel because it burns slowly and for a long time (Sousa 1940).

Although there seem to be comparatively few records in the literature on the uses of *Alvaradoa*, it has an impressive list of common names. Generally, when plants have multiple names across their ranges, they are valued parts of the local economies.

As usual, in the United States where people rarely retain the uses of tropical plants, there is no common name except the genus—alvaradoa. The average citizen will have no idea what you are talking about if that is used as a genus or common name. However, the deeper you go into the tropics, the more names for the shrubs and small trees you will find. In Cuba, it is called *tamarandillo* because of its similarity to the native *tamarindo* (*Lysiloma bahamensis*) and the exotic (*Tamarindus indicus*). The related Cuban endemic *A. arborescens* is *carmin* (scarlet). In Hispaniola, the related *A. haitiensis* is known as *abbé marron* (brown abbey). Jamaica has two endemic species so rare that no names have been recorded for them. The genus is absent from the Virgin Islands, Puerto Rico, and the Lesser Antilles, but it reappears in Yucatan where the Maya call it *bel-cini-chè* (tree that is full of ants). The name presumably is given because ants attend the floral (and extrafloral?) nectaries.

In the United States *Alvaradoa* occurs only in southern Florida, and there only in Miami-Dade County. The literature records them for Monroe County, but that seems to be an error (Coile 2000). These Florida shrubs grow in the edges of rockland hammocks, mostly now in Everglades National Park. Formerly, they were scattered throughout other rockland hammocks in the area, but urbanization has eliminated most of them. Sometimes *Alvaradoa* grows with *Picramnia pentandra*, another member of the family.

The bush sulfur butterfly (*Eurema dina helios*) feeds exclusively on this species. It has perhaps the most restricted range in Florida as it is confined to the region of Miami-Dade County where the plants grow (Gerberg and Arnett 1989).

It is easy enough to imagine how most members of this family arrived in Florida. Fruits on *Simarouba* and *Picramia* are colorful and are eaten by birds. Presumably, avians are the primary dispersal agents within Florida, and perhaps inadvertently they brought them in their digestive tracts from nearby areas. However, it is more difficult to see how *Alvaradoa* fruits might attract birds. The fruits are neither fleshy nor showy, although they do turn pink at one stage. Moreover, they have wings that have prompted

people to describe them as “samaras.” Could these be plants that were brought by people traveling between the Caribbean Islands and peninsular Florida in pre-European times? Their uses outside Florida suggest that possibility.

### *Amaranthus*

(Greek *amarantos*, unfading, an allusion to the lasting quality of the flowers, persistent bracts and sepals)

*achita* (Quechua, Peru); *kiwicha* (Cusco, Quechua, Peru)  
*alegría* (happiness, Mexico)

***Amaranthus hybridus*.** From Britton and Brown 1896.

amaranth (English); *amaran te* (French) *Amaran t(h)* (German);  
*amarant* (Dutch); *amaranto* (Italian, Portuguese, Spanish)  
*bledo* (Spanish); blite (in English by 1420); *breda* (Portuguese)  
*chithal tooro* (bull *A. leucocarpus*, Huastec, San Luis Potosí)  
*chuhugia* [*cuhukkia*] (Hia-ced O’odham, Arizona); *ki’aki* [*giád*]  
(Akimel O’odham, Tohono O’odham, northwestern Sonora and  
southwestern United States)  
*huautli* [*huanhthi*] (Náhuatl, Mexico); *huisquilite* [*huisquilite*] (for *A.*  
*spinosus*, Náhuatl, Mexico); *quelite* (edible greens, from *quilitl*, Náhuatl,  
Mexico); *quintonil espinosa* (spiny *quilit*, *A. spinosus*, Mexico)  
*koyo* (Aymara, Peru)  
*nocuana guezetao naxiñaa* (*nocuana*, edible herb, fruit, or remedy,  
*guezetao* means Moorish, but that often also indicates foreign, *naxiñaa*,  
red, Zapotec); *nocuana laza naxiñaa* (*nocuana*, edible herb, fruit, or  
remedy, *laza*, amaranth, *naxiñaa*, red, Zapotec)  
pigweed (in use by 1844)

***Amaranthus australis*** (southern)

careless (Florida)

*cikiláfáli* (*ciki*, house, *láfáli*, burner, Mikasuki)***Amaranthus hybridus*** (hybrid, because it was similar to two other species; not a hybrid)*ixtez* [*xtez*] (Maya, Yucatan); *quiec tes* (Quiché, Guatemala)*quelite* (Veracruz); *quelite morado* (purple *quelite*, New Mexico)

As a child, I learned never to walk barefoot in a barnyard or pig lot. There are two dangers. One is that neither animal has indoor plumbing; the other is that there may be spiny plants. I grew up calling one kind of spiny herbs “pigweeds,” even though they grew in cattle pastures and not in pig lots. Later I learned that they were *Amaranthus*. The one that was particularly bothersome to tender bare feet was *A. spinosus* (spiny).

The genus *Amaranthus* remains an important food source for many people in the world. In Spanish, the generic name is *bledo*, which is rendered *breda* in Portuguese. These terms originated with Greek *bliton* that was rendered *blitu* in Latin. Ultimately, for English speakers, this was changed into “blite.” This type of name, which cannot be broken down further, is called by linguists a monomorphic lexeme, and is taken as a marker for a long usage, regardless of the language. Historical data on *bledo* or *blite* support that view, so the plants and the name have been with Old World people for thousands of years.

Although the compilers of the *Oxford English Dictionary* were in doubt regarding the relationship, blite probably evolved into a word of derision, “blight.” That suggestion is made and then rejected by the OED (1971), but the historical sequence and origin of blight with farmers and gardeners convince me they are connected.

Blite made its way into English in the first recorded document in 1420. It was not until 1669 that the rendition “blight” appeared. Perhaps the changing attitudes about useful vs. nonuseful plants in the Old World, connected with novel views from the New World, led to the change.

When the first Europeans arrived in the New World, amaranths were among the plants they encountered being used by indigenous people. One of the first records was left by the Gentleman of Elvas about Hernando de Soto’s Spanish troops in the river or swamp of *Cole* [*Ocale*], near what is now the west bank of the Withlacoochee River in Citrus County. This was southwest of the region now known as Ocala. These soldiers were “experiencing great hardship from hunger and bad roads as the land was very poor in maize, low, and very wet, swampy, and covered with dense forests, and the provisions brought from the port were finished. Whenever any village was found there were some *blites* and he who came first gathered them and having stewed them with water and salt, ate them without anything else” (Swanton 1946).

At first, they were not surprised because the plants were well known in their homelands, even if they were not the same species. However, their countrymen soon discovered that some Americans were using their plants in ways never dreamed of in Europe.

A Mexican Spanish name for *Amaranthus* is *quelite*, rendered *kelite* in Belize. *Quelites* served and still serve as the daily food for many people (Linares and Aguirre

1992). An example is the Tarascans of conquest times for whose daily food: "*Maíz, pescados secos, charales y quelites forman la base*" (Corn, dry fish, *charales* [a small bony fish], and *quelites* form the base) (Santamaría 1959). Perhaps the earliest record of Mexicans using *Amaranthus* in the 1500s is from Fray Bernardino de Sahagún, who wrote: "*Otra yerba se come, cocida llámase quintonilli, tiene las hojas anchelas: cuando es pequeña esta yerba es comestible, y cuando ya es grande llámase petzicatl, cuécese con salitre (es decir tequixquitl) exprímese del agua para comerla*" (Another herb is eaten, cooked it is called *quintonilli*; it has narrow leaves. When it is small, this herb is eaten, and when it is big, they call it *petzicatl*, cooked with salt (that is *tequixquitl*) and removing the water to eat it) (Santamaría 1959). *Quintonil* is from *quiltil*, greens, *tonilli*, cooked (Náhuatl). This same plant is the amaranth whose seeds are used to make breads called *alegría* (happiness).

Actually, *alegría* is not only a name for the plant from which *quelites* are taken to make *quintoniles*, but the seeds and the bread are all *alegría*. From the seeds, Mexicans made atole, little tamales called *huauquiltamales*, and a dough. The bread, made by mixing the toasted seeds with sugar and boiling, was commonly sold in markets (Santamaría 1959). Both hemispheres used the leaves as greens, and the seeds were eaten as food. So far so good.

However, at first the priests, and then the remaining devout Catholics, discovered that Aztecs mixed the seeds of *Amaranthus* with blood (sometimes human), and sculpted the resultant dough into "idols" that they offered to their deities. Both practices outraged the pious religious leaders. Catholic priests started a campaign to suppress the practice, and much of it was stamped out, or at least driven underground.

The celebrations that started the campaign against *Amaranthus* revolved around *A. leucocarpus*, plants now called "prince's feather." That species was the one that had been grown in Mexico since ca. 5000 B.C., and the Aztec emperor Moctezuma is said to have received an annual tribute equivalent to 200,000 bushels of seeds from this cultigen (Purseglove 1968). Each seed is usually less than 1 mm in diameter, so one must imagine how many plants and people it would take to gather that many bushels.

Dough made from the seeds (*tzoale*, *tzouali*, *zoale*, *soale*, from Náhuatl *tzoalli*) was made from a plant Aztecs called *uautli* or *huautli*. Historical records show that *tzoalli* seeds were used to make a statue of *Uitzilopochtli* (*uitzilín*, hummingbird, *opochtli*, left-handed) to celebrate his festival during the month of *toxcatl*, which occurred from the last part of April and the first part of May. The first day of the celebration was dedicated to *Tezcatlipoca* (*tezcatl*, mirror, *poca*, brilliant), and culminated in the sacrifice of a human to this deity. Eight days later they began the celebration to *Uitzilopochtli*. From the *tzoale* seeds, they created the idols, and also made sweets and candies that were offered to their deities (Siméon [1885] 1981).

It is not too far from being disgusted with a practice to having the whole organism tainted with that emotion. European farmers would not have liked the *Amaranthus* competing with the foods they were trying to grow in the first place. Adding religious bias to that negative feeling made *Amaranthus* even more undesirable. Maybe that is why Europeans began calling the *Amaranthus* "pigweed," because they were not fit for people, but were served to their barnyard animals.

Regardless, Americans and many other people used *Amaranthus* as food and medicine. Spanish speakers distinguished the individual species with modifiers, e.g.,

*bledo espinoso* for *A. spinosus*. Aztecs called the cooked leaves *quilitl*. That became Hispanized *quelite*, and the name has become generic in Mexican Spanish; it is now applied to many edible greens (Linares and Aguirre 1992). *Huautli* is now applied to fish or insect eggs, and not to a plant at all (Ebeling 1986).

A relative of *Amaranthus* is spinach, so it should not be surprising that the French call both *épinard* (French Antilles). In Creole English in the Dutch Antilles, Belize, and Panama, *Amaranthus* is called *calaloo* [*calaloe*, *pison calaloo*, *callalu*] (a Caribbean name, etymology uncertain). Technically, *calaloo* is the greens from leaves of *Xanthosoma*, but Asian *Colocasia*, also in the Araceae, has been substituted. So has *Amaranthus*.

In the United States, various people used *Amaranthus* as food. Moerman (1998) included 12 species, eaten by the Acoma, Apache (Chiricahua, Mescalero, White Mountain), Cahuila, Cocopa, Gosiute, Havasupai, Hopi, Iroquois, Isleta, Jemes, Keres, Keresan, Klamath, Laguna, Mendocino, Mohegan, Mojave, Montana, Navajo, Papago (Tohono O'odham), Pima (Akimel O'odham), Tewa, and Zuni. Felger and Moser (1985) add the Seri, and Hodgson (2001) added the Cochimi, Guarajío, Northern Tepehuan, Quecha, Tarahumara, Yaqui, and Yavapais. It would not be surprising to learn that all people in the New World used *Amaranthus* leaves and/or seeds.

Not only are *Amaranthus* eaten, but many people have discovered that they may also be used medicinally. The Cherokee used *A. hybridus* and *A. retroflexus* in "Green Corn" medicine, and to stop profuse menstruation (Hamel and Chiltoskey 1975). The Keres used an *Amaranthus* infusion for stomach problems, the Iroquois used it in witchcraft, and the Mohegans treat hoarseness with an infusion (Moerman 1998).

A leaf decoction has been used in Veracruz, Yucatan, and Costa Rica for stomach pain and liver trouble, and a root decoction serves as a diuretic and remedy for bladder problems (Morton 1981, Vásquez and Jácome 1997). Several Central American groups have learned that bathing in a plant decoction relieves fever, and the plant may be applied to external sores and wounds. Crushed or lightly cooked leaves cure sores, especially those that are slow to heal. Roots are also used to wash boils to help them heal (Morton 1981).

In Florida the most common species is *A. australis*, historically called "careless" because it does not care where it grows. This may have been among the plants called *cikiláfâlî* (*ciki*, house, *láfâlî*, burner) by the Miccosukee. They claimed that, when the dead herbs blow like tumbleweeds across a camp, sometimes they get in the cooking fires (Sturtevant 1955). When *cikiláfâlî* did that, there was a good chance that they would set the house on fire. Perhaps that is one reason why the Seminoles kept a cookhouse *chikee* separate from where they slept.

### *Ambrosia*

(From Greek *ambrosios*, delicious, divine, immortal, derived from a, not, *mbros*, mortal; in Greek mythology, the food and drink of the gods)

*Ambrosia trifida*. a. Upper portion of a flowering branch, b. Portion of a flowering raceme. c. Achene. Drawn by Regina O. Hughes. From Reed 1971.

ambrosia (used in English by ca. 1590); *ambrosia* (Italian); *ambrosie* (French); *Ambrosie* (German)

*iubar-sléibhe* (*iubar*, yew, *sléibhe*, heath, Gaelic)

*Ambrosia artemisiifolia* (with leaves like *Artemisia*, sagebrush or wormwood)

*l'ache à dinde* (turkey celery, Quebec)

*alcanfor* (camphor, Cuba)

*altamisa* (transcription of ambrosia, Mexico, Cuba)

*beskambrosia* (bitter ambrosia, Norwegian)

bitter weed

*canhlo'gan onzi-pakinte* (herb to wipe the rear, Lakota); *canhlo'gan was'te'mna* (sweet-smelling herb, Lakota)

hay-fever weed

*herbe à poux* (louse herb, Quebec)

hogbrake [hog-weed, hog-wort] (“hog” is probably derived from Cornish *hoch* or Welsh *hwch*, swine or perhaps yearling; “brake” here meaning thicket; “hot-weed” must be a mistake for “hog-weed”; cf. Small 1933)

*kcicka* (Biloxi)  
*mon-hin-pa* (*mon-hin*’, grass, *pa*, bitter, Osage); *pexhuta pa* (bitter medicine, Dakota)  
*poipiye* (to doctor swellings with, Lakota)  
 [annual, common, short] ragweed (“ragweed” from “ragwort,” where “rag” denotes the incised margins of the leaves)  
 Roman wormwood (“wormwood” from the use as a vermifuge)  
*sarriette* (from Latin *Satureja*, the aromatic old world mint, which must have been confused with New World aromatic composites, Quebec)  
 stammer-wort [stammerwort]  
*vtakrv homv* (*vtakrv*, plant, *homv*, bitter, Muskogee)

***Ambrosia hispida*** (hairy, with stiff trichomes)  
*altamisa de playa* (beach ragweed, Puerto Rico)  
 bay tansy (“tansy” is taken from Medieval Latin *athanasia* and Greek *athanasia*, immortality; akin to “everlasting” or *immortelle* because of the long-lasting flowers; now *Tanacetum vulgare*, Asteraceae; these are coastal plants, hence “bay,” Puerto Rico, Dominica); bay vine (Bahamas)  
*carquesa* (an oven that is used to temper glass, Spanish)  
 coastal ragweed  
*sept Villes* (seven towns, Dominica)  
*tapis vert* (green carpet, Dominica)  
 wormwood (Dominica)

***Ambrosia trifida*** (three-parted)  
 bloody weed (translation of Kiowa by Vestal and Schultes 1939; children broke off a branch to watch the “bloody” liquid exude; revered by the Kiowa)  
 buffalo-weed [buffaloweed]  
*canhlo’gan was’te’mna* (sweet-smelling herb, Lakota)  
 giant [great] ragweed (“ragweed” was first applied to *Senecio*, then to *Ambrosia*)  
*hesterambrosia* (horse ambrosia, Norwegian)  
 horse-cane  
 horse-weed (this is the name that I grew up using in western Kentucky; no one explained it, but we always thought the word “horse” referred to the large size)  
*Taubenkraut* (dove herb, German)  
*yamnu’mnuga iye’ceca* (it is like making noise crunching with teeth, Lakota)

Anyone with an allergy to the pollen of *Ambrosia* will wonder why Linnaeus used the Greek word for immortality to name the genus. He kept quiet about that topic, but he was following the lead of previous authors including Gaspar Bauhin (1560–1624) and Rembert Dodoens (1516–1585) who had used the name for *A. maritima*, a seaside plant growing around the Mediterranean. By the time Linnaeus described *A. artemisiifolia* and

*A. trifida*, both were well-established weeds in Europe (Linnaeus [1753] 1957, Clapham et al. 1987).

Giant ragweed was first found by Melvin Gilmore in archaeological deposits of the Ozark Bluff-Dwellers. Gilmore (1931) wrote: "There is evidence that the ancient Ozark Bluff-Dwellers also had certain other species of plants not cultivated at the present time. The ground for this statement lies in the fact that supplies of the seeds of these other species of plants were carefully put away together with the selected seed of corn, beans, sunflowers, squash and pumpkins." Among the seeds "carefully put away" were those of *A. trifida*. Gilmore argued that the size of the seeds he found were larger than wild plants and therefore ragweed had been cultivated. Payne and Jones (1961) found that the variability in wild *A. trifida* included the sizes found by Gilmore, and concluded that the plants were not cultivated. They suggested that the seeds were probably used for medicine and not food.

A subsequent report of *A. trifida* from an archaeological site near Mobridge, South Dakota, also concluded a medicinal use (Kindscher 1987). However, a third site in west-central Illinois has been studied by Asch and Asch (1982), who concluded that this Woodland period (ca. 1500 B.C.) culture was cultivating *A. trifida*. Their conclusion was based on both the fact that the seed coat was missing in most of the samples (presumably because they had already been processed), and that it was second in abundance to the known cultigen of marsh elder (*Iva annua*).

When Gilmore (1931) talked with an Arikara man about *A. trifida*, he was told, "I do not know how this plant may have served those ancient people, but now I will tell you a use which our people made of it. If you crush the flower heads in your hand you will see that it makes a red stain.... Our people formerly employed the blossoms of this plant to make a red dye." An Omaha also told him that "our people used to make beautiful red stain from its flowering tops." That use is not recorded in Gilmore's (1919) study of the Missouri River tribes, nor is it mentioned by Moerman (1998), although Vestal and Schultes (1939) alluded to it when they reported that the Kiowa revered this plants. Tull (1999) also noted the Omaha use, and that a green dye can be made from the leaves, and that fiber can be extracted from the stem.

There is other documentation that historic tribes used *A. trifida* as a medicine. The Cherokee used *A. trifida* in "Green Corn" medicine, rubbed leaves on insect stings and hives, put juice from leaves on infected toes, and took a leaf infusion to lower fever and to treat pneumonia (Hamel and Chiltoskey 1975). The Iroquois used a decoction to stop diarrhea with bleeding; the Lakota used the seeds medicinally; and the Meskwaki chewed the roots to relieve fear (Moerman 1998). Hocking (1997) recorded use of the plant as an astringent and detergent, and the root was chewed as a sedative among "Wisconsin] tribes" (Payne and Jones 1961).

The Cherokee used *A. artemisiifolia* in "Green Corn" medicine, rubbed leaves on insect stings and hives, put juice from leaves on infected toes, and took an infusion of leaves to lower fever (Hamel and Chiltoskey 1975). The Houma took a decoction of roots for menstrual troubles (Speck 1941).

Farther north, the plants were used by the Dakota, Delaware, Iroquois, Lakota, and Oto (Moerman 1998). It has been reported as used by the Luiseño and Mahuna of California (Moerman 1998), but it is a recently introduced weed there (Hickman 1993). In a rare comment on a "forbidden topic," the Lakota used the leaves for toilet paper

(Kindscher 1987). In Mexico, the entire plant was used in an infusion to aid digestion, as a febrifuge, and to expel worms (Martínez 1969). In Cuba, it is used in aromatic baths against rheumatism, and in decoctions to treat fever (Roig 1945). *Artemisia hispida* is used essentially for the same problems as *A. artemisiifolia*, especially by Caribs (Honychurch 1987).

Millspaugh (1892) considered ragweed useful in treating poison ivy rash, possibly because of its astringency. For that same reason it was applied to other problems of the mucous membranes, including leukorrhea, gonorrhea, diarrhea, dysentery, and enteritis. Plants contain essential oils, including *p*-cymene, limonene, alpha-pinene, and alicyclic ketone (Kindscher 1987).

### *Amelanchier*

(From Provençal *amelanquier*, which in turn is based on *amelanco*, from the Gaulois language)

***Amelanchier arborea*.** From Britton and Brown 1897.

*amélanchier* (French)

*blåhegg* (*blå*, blue, *hegg*, hedge, Norwegian)

*Felsenbirne* (rock pear, German)

*guillomo* (Spanish)

*Felsenmispel* (rock medlar, German); *mespilus* [*mespile*] (first used in English for the medlar, *Mespilus germanica*, about 1398; later expanded to include *Crataegus* and *Amelanchier*)

*pero corvino* (crow pear, Italian); *petites poires* (little pears, Quebec);

*poirier* (pear tree, Quebec)

***Amelanchier arborea* (like a tree)**

June-berry [juneberry]

*poires* (pears, Quebec)

*sa-bas-sa* (Osage)

saskatoon (sometimes applied generically, and other times to *A. alnifolia*, from Cree *misaask-watoomin*; akin to *guzigwa'kominaga'wunk*, thorny wood, Ojibwa, and *bosíkwá'kominûn*, plum berry, Potawatomi)

[common, downy] service-berry [common service-berry, downy serviceberry, sarvice berry, sarvice berry, sarviss tree, sarvas] (“service” derived from *Sorbus*)

shad-blow [shad-blossom, shad-bush] (“shad” is perhaps from Gaelic *sgadan*, herring; “blow” from Old English *blówen*, from the Old Teutonic root *bló*, cognate to Latin *flos*, flower or blossom; some say the name was applied because of the plants being in bloom when shad, *Alosa sapidissima*, migrate back upstream)

sugar plum (Missouri)

There is a single species of *Amelanchier* native to Europe (Mabberley 1997). At first it seems odd that Linnaeus did not name the species; instead it was named by Alfred Rehder (1863–1949) in 1920, while he was curator of the herbarium at Harvard’s Arnold Arboretum. However, Linnaeus called the European plants *Mespilus amelanchier*. Now Linnaeus’s genus *Mespilus* has had most of the species placed in other genera such as *Pyracantha*, *Cotoneaster*, and *Amelanchier*. The Florida species was not named until 1812 when André Michaux described it, also as *Melispus*. Finally, Merritt Lyndon Fernald (1873–1950), another Harvard botanist, gave us *Amelanchier arborea* in 1941.

Across the colder parts of North America, people mixed dried, pounded meat with berries and fat to create what the Cree called *pimekan* (from *pimiy*, grease). That word came into English as “pemmican” by 1801, although European settlers had been using the mixture far longer. This mixture of protein-rich meat, berries to add flavor and serve as a preservative, and fat was essential to surviving the long winters. The food also served as rations for long journeys (Davidson 1999). This mixture was used all across the cold winter belt, from the Iroquois of New York to the Ojibwa of Ontario, and into the Great Plains (Gilmore 1919, Densmore 1928, Yanovsky 1936, King 1984). It was used at least as far south as the Osage and Omaha, who called it *ta'-pshe* (La Flesche 1932).

Steyermark (1963) recorded that the indigenous people of Missouri mixed the dried fruits of *Amelanchier* with cornmeal to make bread. That mixture is more akin to the preparations made by most southeastern people than those farther north. No record was found of people in the southeast using anything like pemmican. Instead, southern people had dishes often based on corn, beans, and squashes, and they dried meat, fruits, and berries for use during the winter months (Hudson 1976). Stews were more a part of the diet in the southeastern people, and they mixed in a variety of plant products (Hudson 1976).

To some people fruits of *Amelanchier* are not that good when taken directly from the plants, but they are said to be improved by drying and cooking (Fernald et al. 1958). Others consider the berries good (Hedrick 1919). Oddly, the small round fruits were compared with pears in French (*poires*), German (*Felsenbirne*), and English where they sometimes were called Maine sweet pear and grape-pears (Hedrick 1919). Fruits of *Amelanchier* were used by people from Alaska and New Brunswick to California and at

least as far southeast as the Cherokee (Gilmore 1919, Moerman 1998). Given the culinary similarity between the Cherokee and their Creek neighbors (Hudson 1976), there is every reason to believe that all southeastern people used the fruits.

Cherokee also used *A. arborea* to expel worms, and as a spring tonic (Hamel and Chiltoskey 1975). The Iroquois used a bark decoction against gonorrhea and as a blood remedy (Moerman 1998). The same people used a fruit infusion to stop the after pains and bleeding from childbirth. The other eastern species have a wider range of recorded uses that perhaps apply to the Florida species.

### *Amianthium*

(Asa Gray named these herbs with Greek *amiantos*, unspotted, pure, alluding to the lack of glands on the perianth)

#### *Amianthium muscaetoxicum* (fly-poison) fly-poison

In 1788, Thomas Walter described herbs from South Carolina he called *Melanthium muscaetoxicum*. When Asa Gray worked on the genus he realized that this species was more closely related to other North American species. Gray created *Amianthium muscaetoxicum* in 1837, based on the species name Walter proposed. As late as Mabberley (1997) the species was put in a third genus, *Zygadenus* [*Zigadenus*] (Greek *zygos*, a yoke, and *aden*, a gland, because of paired glands).

Leaves and bulbs are poisonous, especially to livestock (Steyermark 1963). Although the species grows from Pennsylvania and West Virginia to Missouri and Oklahoma and south to Florida, there seem to be records of people using it only in the Carolinas. The Cherokee used it to treat itch, and to poison unwanted animals (Hamel and Chiltoskey 1975). All plant parts, but especially the bulbs, contain the toxic compounds zygadenine and zygacine (Foster and Caras 1994).

### *Amorpha*

(Greek, *amorphos*, deformed)

*Amorpha fruticosa*. a. Upper part of a plant with flowers, b. Branch with fruits, c. Young leaflets, d. Flower, e. Pistil. f. Fruit cluster. Drawn by Vivian Frazier. From Correll and Correll 1972.

***Amorpha fruticosa*** (shrubby)

*ayikchô:mî* (bitter medicine, Mikasuki); *tohô:mî* [*kado ho-mi*] (*eto*, wood, *home*, bitter, Creek, Muskogee)

bastard indigo (from its use as a source of blue dye); [desert] indigo bush; [dull-leaf, false] indigo

*kitsuhas* (*kitsu*, water, *hatsu*, strings, Pawnee)

lead plant (believed to indicate the presence of lead ore; in use by 1864, probably before)

polecat tree (maybe related to the retting process in preparing dyes)

*tse'-biu-k'a-mon-ta hi* (*tse'-biu-k'a*, frog, *mon'-ça hi*, arrow shaft stalk, Osage)

By the early 1700s, another American plant from the Carolinas had caught the attention of the European horticultural trade. A London book on cultivated plants listed for sale *Barba jovis americana, pseudo-acaciae foliis, flosculus purpureus minimis* (American Jobe's beard, with leaves resembling acacia, flowers very small and purple) (*Anglicici hortulani* 1730). This species appeared in two books in the 1730s and two in the 1740s, and then Linnaeus finalized its name in 1753 as *Amorpha fruticosa*. Somewhere along the

line, it became known in English as “lead plant,” with the belief that lead could be found wherever it grew (OED 1971).

Linnaeus called these shrubs *Amorpha* because the flower has only a banner wrapped about the staminal column. The other four petals that are normally present in legumes are entirely missing. Subsequently, exploration of the Americas has disclosed more kinds, and we now know that there are 15 species in North America (Mabberley 1997). *Amorpha* ranges from Canada through the United States, and barely reaches into Mexico in Baja California and Sonora.

In the eastern United States, there are six *Amorpha* species; those in Florida are *A. fruticosa* and *A. herbacea*. Both species range down most of the peninsula, with only a few individuals of either species known in the southernmost five counties.

Although this is a temperate genus (Wilbur 1975), there seem to be comparatively few records of how it was used by people in the past. Now, the attitude has evolved to the point that the USDA has listed one, *A. fruticosa*, as an invasive species, even though it is rarely encountered even within the heart of its range. Clearly, views of “lead plant” have evolved considerably since Europeans first arrived in the New World.

Native Americans had more regard for the plants. In Florida we know that *A. fruticosa* was called *ayikchó:mî* (Mikasuki). Related Creek names for the same plant were *kado ho-mi* (Muskogee) and *tohó:mî* (Creek).

Florida Seminoles used *ayikchó:mî* against what they termed the “Moving Sickness,” a general malaise with a pain that moved from one area of the body to another (Sturtevant 1955). At least part of that illness seems to have stemmed from gastric distress. Regardless, roots of *Amorpha* were mixed with *Sisyrinchium* and *Andropogon* to treat the malady. A different recipe is given by Oklahoma Seminoles (Howard 1984). They boiled the leaves and stems, and the resultant tea was left to stand overnight. The following day the liquid was reheated and then was ready to use. The “tea” was taken four times a day, before meals and at bedtime, as a general tonic.

For rheumatism pains the doctor chews the *Amorpha* and applies it to the area that hurts (Sturtevant 1955). The Seminoles employed a mixture of medicines for chronic sickness, and the longer an individual was sick, the more plants were included. Sometimes this medicine consisted of 15 plants, and was strong enough potentially to kill the patient. One of the ingredients was *ayikchó:mî*, with buds and small bits of the stem employed. The same plant was given in medicine at birth ceremonies (Sturtevant 1955).

The Omaha of Nebraska used the leaves of *A. canescens* in some of the same ways as the Seminoles (Gilmore 1919). In addition to the shared uses, the Omaha had others, including blowing powdered, dried leaves into cuts and open wounds to help them heal. They also considered *Amorpha* a counter-irritant; one end of a stick was attached to skin with saliva, then burned down from the opposite end until the fire touched the skin (Gilmore 1919). The Meskwaki also used *A. fruticosa* as medicine (King 1984).

In their Lakota-related language, the Omaha called *A. canescens* shrubs *te-hunton-hi* (buffalo belly plant). This name was derived from the fact that blooming is synchronous with the buffalo rutting season (Gilmore 1919). Williamson (1987) summarized their worldview when he wrote: “Native Americans lived very close to the land. Whether they were hunters, gatherers, or agriculturists, all groups depended heavily on the grace of nature and their own wits to survive. They had to learn weather patterns, the cycles of

plant growth, and the movement of game in order to live.” Sometimes, their common names reflect that diverse knowledge.

Several other people left other applications of *A. fruticosa*. Among the Pawnee, the plant was called *kitsuhash* (water-strings). Presumably, that reference is like the one to *A. canescens*, which was called in English “shoestrings,” and referred to long tough roots. Among the Kiowa, the long stems were used as a foundation for bedding material (Vestal and Schultes 1939). Moreover, stems were made into mats, rugs, and bedding. The Lakota, like the Seminoles, used the stems to make arrows (Sturtevant 1955). The Pawnee also spread *Amorpha* on the ground to receive meat while butchering to keep it clean (Gilmore, 1919).

There are other records of two related species being used in several other ways that probably apply to Florida plants. *Amorpha canescens*, which is essentially the Great Plains species, ranging from Michigan to Montana and south to New Mexico and Texas, was called “prairie shoestrings,” or just “shoestrings” (Coffey 1993). It was also called “wild-tea” because at least the Oglala Sioux made a drink of the leaves. The Ojibwa took a decoction of roots for stomach pain, and the Meskwaki of Iowa used an infusion of leaves to kill pinworms or other intestinal worms. Infusions also were applied to eczema. The Oglala also crushed dried leaves as finely as possible, mixed them with fat, and smoked the mixture. That particular preparation must have been medicinal, although it is not specifically stated as such (Moerman 1998).

Finally, *A. nana*, which grows from Minnesota and the Dakotas south to Oklahoma and New Mexico, was used by the Navajo (Elmore 1944). These Athabascan people call the plants *ni'pis-tjah* (plant that is lying on the ground). The Navajos use it as a *tc'iic'azee* (cold medicine), by making a snuff, which they used against catarrh. English names for the plant are largely lackluster, including small-leaved bird's foot, small-leaved deer weed, false indigo, shoestrings, and indigo bush. The latest floras on the region call it simply “dwarf indigo,” translating the Latin name.

The medical uses have a chemical basis, as there is evidence that the plants contain alkaloids (Diggs et al. 1999). Moreover, livestock browsing the shrubs are poisoned, but poisons in the correct dosages are medicines. Other bioactive chemicals are also known, and *Amorpha* contains cannabinoid-like compounds, essential oils, rotenoids, flavanones, and isoflavones (Kemal et al. 1979, Ognyanov and Somleva 1980, Rozsa et al. 1982, Somleva and Ognyanov 1985, Li et al. 1993, Crombie and Whiting 1998, Ohyama et al. 1998, Lis and Gora 2001). Several of these compounds inhibit skin tumors and microbes (Mitscher et al. 1981, 1985, Petkov et al. 1983, Konoshima et al. 1993, Li et al. 1993).

English names for *Amorpha* are not nearly as interesting, probably because the plants had less importance in European-derived cultures. The most widespread known use for *Amorpha* is as a dye source. Like the highly valued blue from true indigo (*Indigofera suffruticosa*), at least *A. fruticosa* produced a blue dye, although some say it was inferior to true indigo. That usage resulted in the plants being known as “bastard indigo,” “dull-leaf indigo,” “false indigo,” “indigo bush,” and “desert indigo bush.” While it may not be immediately obvious, the common name “polecat tree,” recorded for northern Florida in the 1930s (Baker 1938), probably also reflects usage as a dye plant. Some accounts of retting and then mixing plants with mordants in preparing plant materials to use as dyes mention a particularly offensive odor.

That there was widespread use of *Amorpha* among indigenous people as a blue dye should not be surprising. Blue was an important color to many tribes; it is the color of the sky, and to some the color of a cardinal point. To the Hopi, blue was the color of the southwest. Zuni considered blue the color of the west (Williamson [1837] 1962). Plants that provided dyes colored like the cardinal points were regarded with reverence. Colors symbolized order in the world. Order is a lesson that would aid modern chaotic worldviews bent on “using up” the world’s resources.

### *Ampelopsis*

(Greek *ampelos*, a vine, *kissos*, ivy; referring to foliage and similarity to *Cissus*; created by André Michaux, cf. Taylor and Norman 2002)

***Ampelopsis arborea*.** From Britton and Brown 1897.

***Ampelopsis arborea*** (tree; why Linnaeus chose to call these twiners the “tree” is one of those unexplained quirks of his sometimes bizarre sense of humor)

*ha’fáli* (Mikasuki, fide Stirling 1941; however, Sturtevant 1955 found *ha’fáli* and *hili:háhli* being used for *Toxicodendron radicans*; see also *Parthenocissus* and Poison-ivy)

*ifá imittó* (*ifá*, dog, *im*, its, *ittó*, tree, Koasati; same name for *Parthenocissus*)

*parrita de playa* (little beach vine, Tamaulipas)

pepper-vine (USA)

*Schreinrebe* (basket vine, German)

*vigne vierge* (maiden vine, French)

Neither J.K.Small nor anyone else gives us a clue why pepper is associated with this climber. Probably, the name came into existence because the oxalic acid in the leaves and stems made it “peppery,” but it does not seem to have been recorded. We know, at least, that several members of the Vitaceae have vegetative parts loaded with oxalic acid. It is so bad in some that people who work in vineyards develop painful rashes from contact with the plants. Tull (1999) warns that people have died from eating Virginia creeper (*Parthenocissus quinquefolia*) fruits. Others, with milder poisoning, have their kidneys damaged for life. Considering that, at one time, Virginia creeper was considered an *Ampelopsis*, is reason for being careful.

As now delimited, *Ampelopsis* consists of 25 species, occurring in temperate and subtropical America and Asia (Mabberley 1997). Most of the species are Asian, and only three seem to be in North America. Those American species are the pepper vine *A. arborea*, the partly sympatric *A. cordata* that grows in the United States and Mexico (Veracruz, Chiapas, Yucatan), and *A. mexicana* that grows from Sonora to Chiapas.

Of these species, both *A. arborea* and *A. cordata* have been used as a dye. According to Tull (1999), they are both good for dyeing gold and brown, if the vine tips and leaves are used with alum. This is a solar dye, where the plant material is added to water in a gallon jar, and left for a week or so. When the water is colored, wool is put in the dyebath. A gold color results, which Tull considers outstanding. If the alum is not used, the color is brown, which can be darkened through various shades by using copper or iron mordants.

The late Julian Steyermark (1963) wrote of *Ampelopsis cordata*: “In August the fruit, about the size of a pea, begins to ripen, turning from green to changing shades of orange, rose, purple, and finally turquoise blue. It is very ornamental in this multicolored display, and is commonly eaten by songbirds, such as brown thrashers, wood thrush, and others.” He could just as well have been talking about *A. arborea*.

Maybe the fruits of *A. arborea* are blacker than “turquoise blue,” but they are just as easily seen by foraging birds. Indeed, the plants spring up wherever there is a perch for birds to sit. Once established in open areas, they may sprawl long distances if there is not a nearby support. These mats of pepper vine may be a meter or more in thickness and effectively shade out other plants, native and alien. One study done in southern peninsular Florida found *A. arborea* in every habitat type (Austin et al. 1987b).

Given that birds, and probably other vertebrates, actively move the plants from place to place, why is neither of the two eastern U.S. species in the Bahamas?

### *Amphicarpaea*

(From Greek *amphi*, of both kinds, and *carpos*, fruit, the allusion to two kinds of fruits, aboveground and belowground; also spelled *Amphicarpa*)

***Amphicarpaea bracteata*** (with leaf-like structures [bracts] on the flower-cluster)

American licorice

*a?napa-hkow* (he conceals food in the ground, Menomini); *assanciko* (Ojibwa); *astahcikow* (Cree); *assantamin* (Strachey in [1612] 1953 wrote

the word as *assentammens*, *ossantamens*, and *ottassantamens*; the same year Capt. John Smith wrote *assentamens*; all of these Powhatan words they translated as “peas”; the Powhatan has the same root as Cree /*astaht-*/, Ojibwa

***Amphicarpaea bracteata*.** From Britton and Brown 1897.

/*assant-*/ and means “concealed by the ground”; the final element is /*\*-min-i-*/, berry, drupe, grain)

*ati-kuraru* (*atit*, beans, *ku*, its, *uraru*, earth, ground, Pawnee)

*bûgwûdj'miskodi'simin* (unusual reddish bean, Ojibwa)

goober (from Angolese *nguba*, mostly used for the peanut, *Arachis hypogaea*, South)

*hinbthi-abe* (*hinbthi-hi*, bean plant, Omaha-Ponca); *hon-bthin-çu* (Osage); *honink-boije* (Winnebago); *maka ta onmnicha* [*onmnicha*] (*maka*, ground, *ta*, its, *onmnicha*, beans, Dakota)

hog-pea (North Carolina); [wild, wild-bean, pea] vine

[American] hog peanut; [ground, wild] peanut

In 1753, Linnaeus knew these plants only from Jan Gronovius’s description in his *Flora Virginica* and the specimen collected by John Clayton. Neither Linnaeus nor the others seemed to realized that the plants had cleistogamous flowers that produced underground fruits larger than those aboveground. To Linnaeus’s credit, he did realize that the plants were similar to what we now call *Apios*, and he put both in the genus *Glycine* (soybean).

The first record of these food plants was given by Strachey and Capt. John Smith in 1612. However, those obscure references to American “peas” used by people around the Chesapeake Bay were lost on most Europeans. Later it was rediscovered that indigenous people ate the subterranean fruits. The Cherokee used these seeds for food and sometimes

made bean bread of them (Hamel and Chiltoskey 1975, Moerman 1998). The Dakota, Omaha, Pawnee, and Ponca thought the seeds too small to be used alone, but mixed them with other foods to add taste and nutritive value (Gilmore 1919). The Meskwaki, like the other people in the Missouri River region, stole hoards of fruits from mice and voles (Moerman 1998). The Osage and Ojibwa treated them similarly (La Flesche 1932, Moerman 1998). At least the Omaha also ate the small roots (Gilmore 1919). Yanovsky (1936) had records of people eating *Amphicarpaea* throughout the eastern states.

Gilmore (1919) was one of the first to record this particular species being taken from the stores of voles, but the Shoshone woman Sacajawea had shown Lewis and Clark how to rob such stashes from a variety of animals in 1804–1805 (De Voto 1981). One of Gilmore's Pawnee informants wrote to him in 1913: "We call them *atikuraru*... In winter time the women robbed rat's [*sic*] nests and got big piles of them. Nowadays when the old women see lima beans they say they look like *atikuraru* in Nebraska." Dakota women also ate the smaller aerial beans, which were about the size of lentils. These same women confided that they never robbed the rodent nests without leaving some food in exchange. Often, they left corn and replaced an equal quantity to what they took.

During the Civil War, Porcher (1863) wrote, "The subterranean pod is cultivated as a vegetable." Fernald et al. (1958) thought the beans good enough to dig, at least when camping.

Several tribes also considered the plants medicinal (Moerman 1998). The Cherokee used an infusion of the root to treat diarrhea, and blew it on snakebites to cure them (Hamel and Chiltoskey 1975). The Iroquois mixed the plants with others to treat a bad stomach caused by tuberculosis. The Lakota made a poultice of the leaves and used it to treat swellings. The Ojibwa mixed the root with others to make a physic (Densmore 1928).

### *Amyris*

(Greek for much balsam)

*Amyris balsamifera* (balsam bearing)

balsam torchwood (Florida)

*bois chandelle* (candle tree, Hispaniola); candil (simple oil lamp, Venezuela)

*bois des roses* (rosewood, Puerto Rico)

*cuaba [blanca, de monte]* (Taino name for the tree [white, wild], Cuba)

*Amyris elemifera*. a. Flowering branch, b. Leaf outline, c. Flower triad, side view, d. Flower triad from above, e. Flower longitudinally dissected, f. Floral diagram, g. Fruiting branch. Drawn by Priscilia Fawcett. From Correll and Correll 1982.

*guaconejo* (Hispaniola)

*limoncillo* (little lemon, Mexico)

*quigua [tigua]* (Cariban?, Venezuela)

*úsim yuera* (kills little boys, Mayo, Sonora)

*rosewood* (Puerto Rico, Jamaica)

*Amyris elemifera* (bearing a fragrant gum)

amyris-wood (Jamaica)

*bois chandelle* (candle wood, French Islands); *bois chandelle blanc* (white candle wood, Guadeloupe); *bois flambeau* (flaming wood, Guadeloupe); candle wood (USA, Virgin Islands); *chandelle blanc* (white candle, Hispaniola); *chandelle marron* (wild candle, Hispaniola); white candlewood (Cayman Islands)

*bois pini* (pine wood, Guadeloupe); waika pine (Belize)

*chilillo* (dull, Honduras)

*cuaba amarilla de costa* (yellow coastal *cuaba*, Cuba); *cuaba de costa* (coastal *cuaba*, Cuba); *cuabilla* (little *cuaba*, Cuba, Puerto Rico)  
*flambouyant* (St. John; name usually given to introduced *Delonix*)  
*guaconejo* (big *cuaba*, Hispaniola)  
*melón* (dull, El Salvador),  
*palo de tea* (torch tree, Hispaniola); *tea* (derived from Latin *taeda*, torch, Spanish from Puerto Rico to Panama); *teilla* (little torch, Puerto Rico); torchwood (Bahamas, Jamaica, USA, Virgin Islands); white torch (Bahamas)  
*pimienta* (spicy, Honduras)  
*roldán* (twisted or talkative, El Salvador)  
*sea amyris* (USA)  
*taray* (tamarisk, Honduras)  
*trois paroles* (three words or promises, Hispaniola)

Formerly, there was a forest along Florida's eastern coast. The continuous canopy ranged from Key West to a little north of Cape Canaveral. This narrow strip of trees was composed of virtually all tropical taxa in the south, and an increasing number of temperate species toward the north. Yet, this whole length, from latitude 24°55" to 29° N, contained torchwood, *Amyris elemifera*. From Key West, the same species grew south through the Bahamas, Cuba, Jamaica, Hispaniola, Puerto Rico, Virgin Islands, the Lesser Antilles from St. Martin to St. Vincent, Grenadines, Grenada, and in Guatemala, Belize, Honduras, and El Salvador. Curiously, it has never been found in Mexico.

If you visit one of the remnants of this long coastal forest in Florida, you will find these shrubs or trees still scattered in isolated islands of vegetation that have survived urbanization. Walk up to one and pick a leaf, crush either the whole leaf or one of the usually three leaflets, and the aroma of citrus fills the air. Cultures throughout the world know that aromatic plants are useful, and certainly torchwood is among those.

Perhaps the most widespread use of "torchwood" is noted by its common name in English. In addition, it is the "white torch" (Bahamas) or "white candlewood" (Cayman Islands).

In Spanish use as a torch is most often indicated by calling it *tea* (torch). Although our English "torch" and the Latin *taeda* somewhat resemble each other, they are thought to have distinct origins. It appears that "torch" came to English from Latin *torquere*, to twist. The relationship is close, however, as often the end of a resinous stick, like pine, was lighted. Yet, a light was more easily obtained with a twisted bunch of grasses or straw. Either way, the result provided illumination to show the way in a pre-battery era. In British English, a flashlight is still called a "torch."

In the Americas, one of the dominant uses of torches from *Amyris*, and probably other woods also, was for night-fishing, especially for crawfish (spiny lobsters). The names give an idea of the geographic and cultural distribution of this practice. In English areas *Amyris* was also called "candle wood" (USA, Virgin Islands). French areas called it *bois chandelle* (French Islands), *bois chandelle blanc* (Guadeloupe), *chandelle marran* (Hispaniola), *chandelle blanc* (Hispaniola), and *bois flambeau* (Guadeloupe). "Flambouyant" (St. John) in English may be related to the French *bois flambeau*, but "flambouyant" is usually applied to the poinciana (*Delonix regia*) and its extravagant red

flowers. French *bois pini* (Guadeloupe) may be given because the stems smell somewhat like pine when they are cut. In Hispaniola, and perhaps elsewhere, it is *palo de tea*. As with so many common names, Puerto Rico is different, with *teilla* a diminutive form of *tea*.

Some of the other names have no obvious relationship to torches. In English, some are artificial, as in “sea amyris” (USA), and probably “amyris-wood” (Jamaica). Users rarely are versed in Greek, and the probability of them using such names is almost non-existent. Those names surely came from academics who had not bothered to talk with the people. The name “waika pine” (Belize) seems like an English name, but it is not clear what “waika” may be.

In the Greater Antilles, the plants are some variant of *cuaba*. That word is Taino, and originally referred to the related *A. balsamifera*. Perhaps at the time of European contact, the term meant any fragrant plant. In Cuba, *A. elemifera* is *cuaba de costa*, *cuaba amarilla de costa*, or *cuabilla* (Cuba, Puerto Rico). In Hispaniola, it is *guaconejo* (big *cuaba*). Some of the original meaning of *cuaba* may be revealed in that *Suriana* is called *cuabilla de la costa*. This plant (“bay cedar” in English) has leaves that, when crushed, give a fragrance similar to *Amyris*.

In Honduras, people call the trees *chilillo* and in El Salvador it is *melón*. At first, those seem to have nothing in common, but both turn out to have slang meanings of stupid or dull. The other Salvadorean name *roldán* may be related, or may simply refer to a twisted trunk. Surely, *pimienta* (Honduras) has a literal translation referring to the fragrance of the leaves, or even their taste. The Honduran name *taray* (tamarisk) seems to be totally unrelated.

Torches were not the only use that people had for *Amyris*. The wood is hard, heavy, strong, close-grained, extremely durable, and takes a brilliant polish (Little and Wadsworth 1964). Moreover, it is repellent to dry wood termites. Its high resin content allows green wood to burn, and green or dry it made for quick-burning cooking fires. Wood was also used as posts, for furniture and cabinet-making. However, in many areas within and outside Florida trees are so rare and small they would no longer serve those purposes.

In addition to the wood, other parts served medicinal purposes. Leaf decoctions or leafy branch tips were both used. Leaf decoctions in the Bahamas are used as a febrifuge, and applied to cuts and sores (Morton 1981). The decoction also helps reduce fever in cases of diarrhea (Hocking 1997). In Venezuela, the same decoction was used against venereal diseases (Roig 1945).

Also in the Bahamas, leaves were boiled with *Myrcianthes fragrans* and this mixed decoction was used to treat flu internally, and externally as a bath to speed recovery. This decoction mixed with *Sideroxylan americanum* was taken to ensure good recovery after childbirth (Morton 1981).

In the Caicos Islands, leafy branch tips are boiled and the resultant tea drunk to stop diarrhea. When the branch tips are boiled with *lignum vitae* (*Guajacum sanctum*) and *Myrcianthes fragrans* they yield a bath used to reduce fever.

In Cuba the root is macerated, mixed with sweet wine, and left in the sun for 9 days. The mixture then is used against shortness of breath (Roig 1945).

The most famous use is as a source of American or West Indian or Yucatán elemí. Gums of several different oleoresins of varying origins are called “elemí.” This elemí is

used in lacquers, and medicinally; it has been official in ten or more pharmacopoeias (Hocking 1997). The resins are related to one of the commercial compounds called “Balm of Gilead” (*A. gileadensis*).

*Amyris elemifera* is not the only source of elemi. Indeed, the other most important source is *A. balsamifera*. Both species are used to extract an essential oil containing caryophyllene, cadinene, and cadinol (Lawless 1995). These oils are used to make varnishes, in medicines, in perfumery, cosmetics, and soaps (Hocking 1997). The oils also are used in incense, where they are known as “rosewood,” “rhodium wood,” or “balsam tree bark.”

In Florida, *A. balsamifera* has never been found anywhere except in one Miami hammock. However, its range is much greater than *A. elemifera*, going from Miami south to Venezuela and Colombia, and up along Mesoamerica through Mexico to Sonora. This species shares several names with *A. elemifera*, being called *cuaba*, *cuaba blanca*, *cuaba de monte* (Cuba), *guaconejo* or *bois chandelle* (Hispaniola), *candil* (Venezuela), balsam torchwood, and *bois des roses* (Liogier 1974, Hocking 1997).

On the mainland, *A. balsamifera* has other names. Throughout Mexico, the most common name is *limoncillo* (little lemon), which it does resemble in many respects. People in Sonora say it also smells lemony when burned. The Mayo in Sonora call the tree *úsim yuera* (kills little boys), but cannot explain that application (Yetman and Van Devender 2001). Nor can they explain why they also call *Agonandra racemosa* (Opiliaceae) by the same Mayo name. In Venezuela, the tree is *quigua* or *tigua*, which may be Cariban words.

A number of *Amyris* species have been studied chemically. *Amyris elemifera* was found to have 41 chemical components, but beta-caryophyllene, caryophyllene oxide, and alpha-eudesmol are the major ones (Pino et al. 2000). Ragosti et al. (1998) also found texalin, an oxazole, in *A. elemifera*.

Within *Amyris*, the most common chemicals besides the essential oils are coumarins. These have been found in *A. balsamifera* (Burke and Parkins 1979), *A. diaptrya* (Laguna 1984), *A. elemifera* (Rastogi et al. 1998), *A. madreensis* (Dominguez et al. 1977), *A. texana* (Fuente et al. 1991), *A. lineata* (Laguna 1985, Laguna et al. 1987), and *A. simplicifolia* (Hernan et al. 1974). Related chemicals known from the genus are benzamides (Hasbun and Castro 1988), dihydrostyrilamides (Hasbun et al. 1988), and furoquinolines (Fuente et al. 1991).

Other species are known to have alkaloids (Laguna 1984), nicotinamides (Burke and Parkins 1978), and sesquiterpenes (Rohmer et al. 1977). Trees also contain a wide array of essential oil components (Beek et al. 1989), with *A. diaptrya* having more than 80 (Adams et al. 1998). In addition to being antibacterial and antifungal (Rastogi et al. 1998), Badawi et al. (1981) have suggested that extracts from *Amyris* may be useful against cancer.

*Amyris* consists of 40 species in tropical America (Mabberley 1997). Clearly, its potential medicinal and economic importance did not escape the early explorers of the region. *Amyris* was named by Patrick Browne (1720–1790) in his book *Civil and Natural History of Jamaica*, published in 1756. Not long afterward, Michel Adanson (1727–1806) renamed it *Elemi* in 1762, so both these men were aware of its medicinal potential.

In Haiti *trois paroles* is an intriguing name for *A. elemifera*. Technically, *trois paroles* means simply “three words.” However, the word *parole* is idiomatically used as a

promise. For example, *manquer á sa parole* (to pledge one's word) and *tenir parole* (to keep one's word). Could it be that *trois paroles* is an illusion to dishonesty? If so, what or who is the guilty party? The tree or the person? Might it be that since *Amyris* smells like a citrus, it "promises" to give fruit, but fails to produce?

### *Andropogon*

(From Greek *andros*, man, *pogon*, a beard; the hairy spikelets resembled a man's beard to Linnaeus)

***Andropogon.*** *Andropogon floridanus* .

From Hitchcock and Chase 1950.

*Andropogon gerardii* . From

Hitchcock and Chase 1950.

*Andropogon glomeratus* . From

Institute of Food and Agricultural Sciences. *Andropogon virginicus* .

Drawn by P.N. Honychurch.

*barbón* (bearded one, Quebec); *Bartgras* (beard grass, German)

bluestem (in use by 1864 for *A. gerardii*, because of the bluish, glaucous leaf sheathes along the stems; subsequently applied to several species of *Andropogon* and *Schizachyrium*)

*Hühnerfuss* (hen foot, German)

*sanguinelle* (little bloody one, Italian)

***Andropogon floridanus*** (of Florida)

Florida bluestem

*pahikitisci* [*pahce chate*] (grass red, Mikasuki); *pahatâ:fi* (*pahi*, grass, *tâ:fi*, broad, Mikasuki); *pahci* (*páhce*, *pv'he*, grass, Creek, Muskogee)

***Andropogon gerardii*** (named for French botanist Louis Gerard, 1733–1819) (= *Andropogon furcatus* of older literature)

*barbón de Gerard* (Gerard's beard, Canada)

big bluestem (named for its height, growing to 2 m tall)

*hade-zhide* (*hade*, hay, *zhide*, red, Omaha-Ponca)

*múckode'kanes* (small prairie, Ojibwa)

*pe'-čka zhu-dse* (*pe'*, forehead, *čka*, white, *zhu-dse*, red, Osage; a sacred plant)

turkeyfoot

***Andropogon glomeratus*** (clustered)

bushy beard grass [bushy beardgrass]; *yerba barbuda* (bearded herb, Puerto Rico)

bushy bluestem

*ch'it-suuk* (*ch'it*, simple term for *Thrinax* palm, *sak*, white, Maya, Yucatán)

*matojillo* (little grass, Puerto Rico)

*matojo escoba de fogón* (grass for the oven broom, Puerto Rico)

*pajón* (big grass, Dominican Republic)

*panache* (plume, Haiti)

*wi-ti sara'k* (root grass, Catawba)

***Andropogon virginicus*** (of Virginia)

*l'arbre á balai* [or probably *l'herbe á balai*] (broom grass, Houma, Louisiana)

*ashuck hooma* (red grass, Chickasaw, cf. Romans [1775] 1961; *hashshok* (grass, *homma*, red, cf. Munro and Willmond 1994); *hashuk ban̄si* (*hanshuk*, grass, *isht bashpoa*, a broom, Choctaw)

*barba de velho* (old man's beard, Ilha Marajó, Brazil); Virginia beard-grass

[Virginia, yellow, yellow-sedge] bluestem

broom sedge [sage] (early settlers employed the culms of this grass as brooms, hence the name, Steyermark 1963; only books call it "sedge"); broom sedge bluestem [broomsedge bluestem]; brown sedge (Puerto Rico)

*capim membeca* (*capim*, grass; *membeca* from Tupí *me'mbeka*, smooth, Ilha Marajó, Brazil)

*escoba* (broom, New Mexico)

fever grass

*matojo de escoba* (broom grass, Puerto Rico)

*pahikitiscī* (red grass, Mikasuki)

*wi-ti· sara 'k* [*surá-k*] (root grass, Catawba)

In 1541, when de Soto's expedition reached southeastern Arkansas, a group was sent to the northwest to explore the countryside. The record they left was probably the first European account of tall-grass prairie. One of the leaders of the smaller group was Luiz Hernández Bidema, who wrote of coming to "some wide plains, on which grew a plant [*Andropogon*] so rank and high, that even on horseback we could not break our way through" (Swanton 1939). That plant would have been *A. gerardii*.

Apparently throughout its range, the stems of *Andropogon* have been used in thatching (Gilmore 1919, Jones 1936, LeCointe 1947, Pittier 1957). Within historic times, the Omaha and Ponca used *Andropogon* on poles to support earth coverings of lodges (Gilmore 1919). To demonstrate and test some of the old methods at the "Fort Ancient" site in Dayton, Ohio, several buildings have been made with *A. gerardii* thatch (Daumeyer 2002). Similar to use as thatch is the use in making cradles, as lining for cradles, graves, and cache pits, and as bedding materials (Dellinger 1932, Jones 1936, Daumeyer 2002, Standifer 2003). Webb and Funkhouser (1936) interpreted other remains as the remnants of grasses used for seating and floor coverings.

Houses were not the only things covered with the grass. Gilmore (1931) discovered that *A. gerardii* had been used to make breech-clouts. Not only could the belt be made of the cords, but a wisp of the longest basal leaves "was taken and a knot tied at the lower end...in putting it on the knot on the end of the wisp was tucked under the girdle at the back, just over the lumbar vertebrae. Then the wisp was passed between the thighs and up in front under the girdle and the distal end was draped over it in the front." He did not know what to make of the many discarded garments until a mummified body of a man was found with one of them in place.

Stems and leaves were widely used to make cords, ropes, and strings for weaving. Gilmore (1931) noted that, for this purpose, "a handful of the fallen basal blades lying at the base of the stalks in a loose mat all over the ground on the prairie was grasped and twisted, lifted slightly and twisted again, until a rope of the desired length was formed; this method is well known to every farmer who makes by hand a temporary rope from a straw pile or haystack." Gilmore (1931) identified ropes and cords at the Ozark Bluff-Dweller site in Arkansas made from big bluestem, and later Whitford (1941) recorded the same preparation in Ohio.

Those same cords were used to weave net bags (Gilmore 1931, Whitford 1941). There are prehistoric and historical records of those cords being used in footwear; sandals for warm weather, and insoles for warm padding in winter moccasins (Gilmore 1931, Webb and Funkhouser 1936, Whitford 1941, Standifer et al. 2003). The twisted stems were even woven into "overshoes" at the Ozark Bluff-Dweller site (Gilmore 1931).

Young boys of the Omaha and Ponca of Nebraska used *A. gerardii* stems, termed *peska*, to make arrows (Gilmore 1919). Arikara, Hidatsa, and Mandan of North and South

Dakota also used them, inserting a thorn from *Crataegus* for the arrow point. The arrows were used primarily to hunt frogs in training for larger game.

At least the Cherokee made a yellow dye of *A. virginicus* (Hamel and Chiltoskey 1975). Tull (1999) recorded a similar use in Texas.

The most widespread application of the genus seems to have been as medicine. The Ojibwa made a root decoction of *A. gerardii* to relieve stomach pain and as a diuretic (Densmore 1928). Gilmore (1919) learned from an Oto medicine man that decoctions of *A. gerardii* lower leaf blades were made to treat general debility where the cause was unknown. The remedy was thought to reduce fever.

The Cherokee used *A. virginicus* to stop diarrhea, in “Green Corn” medicine, to treat piles, poison ivy rash, frostbite, and to help cure sores (Hamel and Chiltoskey 1975). In the Bahama Out Islands, the sweetened plant decoction is drunk as a febrifuge (Morton 1981). The Brazilians take a decoction to relieve urinary problems (LeCointe 1947). The grass is used in domestic medicine in the United States as an alterative, tonic, and diuretic to treat erysipelas (Hocking 1997). The Houma used some *Andropogon* to strengthen mother and baby in pregnancy (Speck 1941). The Catawba of the coastal Carolinas used *A. glomeratus* roots for backaches (Moerman 1998). Several other species of *Andropogon* are used to treat fevers and considered diuretic (LeCointe 1947, Duke and Vásquez 1994, Mors et al. 2000).

Perhaps the greatest number of medical uses is recorded for *A. floridanus* (Sturtevant 1955). One of the common uses of this grass was as an analgesic. For that purpose it was mixed with other plants or used alone. An infusion was taken for “Wolf Sickness” (vomiting, stomach pain, diarrhea, frequent urination), “Moving Sickness” (moving pain in waist), and both drunk and used as a bath for “Gopher-Tortoise Sickness” (cough, dry throat, noisy chest).

### *Angadenia*

(From Greek *ang*, vessel, box, case, and *aden*, gland, probably alluding to the stigma being enclosed)

*Angadenia berteroi* (named for Carlo Luigi Guiseppe Bertero, 1789–1831, an Italian explorer of the American tropics. Because of a curious situation where an original author erroneously described two supposed species that are really one, the Corrells applied another name to the same plant in the Bahamas. They called them *Angadenia sagraei*, for Ramon de la Sagra,

***Angadenia berterii*.** a. Flowering branch, b. Flower from above, c. Flower longitudinally dissected, d. Floral diagram, e. Fruits, f. Seed with coma, g. Seed. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982.

1798–1871, Spanish botanist who explored Cuba. Not only was it strange that Alphonse DeCandolle proposed both *Echites berterii* and *E. sagraei*, but Miers transferred them both to *Angadenia* without realizing that they were the same plants.)

golden trumpet (Florida)

*ismo:kha:kâ:ki:hiliswâ* (*enokketv*, sickness, *heleswv*, medicine, Creek)

lice-root (Bahamas)

*sanahahcayikî* (chronic sickness medicine, Mikasuki)

*tumba gente* (person tumbler, Dominican Republic)

One of the new plants that the Seminoles encountered when they came to southern Florida was the geographically restricted *Angadenia berterii*. These plants live only in the pine rocklands of Miami-Dade and Monroe Counties, and their restricted range and habitat have led to them being called “pineland golden trumpet.” The species is threatened in Florida (Coile 2000).

Among the Seminoles, the “golden trumpet” was called *sanahahcayikî* (Mikasuki) or *ismo:kha:kâ:ki:hiliswâ* (Creek). For the cure of the intercourse taboo, the doctor took small sections of the roots. These were boiled in water for 2 to 3 hours. The medicine was

blessed, and then given to the patient. In cases of chronic illness, the roots were also boiled to produce a decoction. That medicine was either drunk for internal problems or applied directly to persistent external sores.

No other people in Florida have a record of using the plants, not even the newer settlers from Cuba. However, people in the Bahamas call the small shrub “lice-root,” and that name suggests that they employed it. Similarly, in Hispaniola it is *tumba gente*. That name is reminiscent of *tumba-vaqueros*, which is used in Mexico for many members of the family Convolvulaceae. Liogier (1974) does not indicate in Hispaniola if the plant is used as a laxative, but the similarity of names to those in Mexico suggest that.

This is a small genus, with only two species (Mabberley 1997). The second is endemic to Cuba. Although *Angadenia* was described by British botanist John Miers (1789–1879) in 1878, the species were considered part of *Rhabdadenia* for many years. John K. Small even described the Florida population as a distinct species he called *Rhabdadenia corallicola*. However, as discerning as he was, he rarely examined floras of nearby regions to see if the plants he published as new really were different from existing species.

### *Angelica*

(From Greek *angelikos*, a messenger or angel, referring to the cordial and medicinal properties of some species; akin to Akkadian *kalu*, messenger)

***Angelica venenosa*. Britton and Brown  
1896.**

*angelica* (Italian, Spanish); *Angelick* (German in 1542); *angelick* (Dutch in 1549); *angélique* (French); *Engelwurz* (angel herb, German)  
ground ash (probably comparing the leaves with those of *Fraxinus*)

*heptaphyton* (from Greek *hepta*, seven, and *phyton*, plant, probably alluding to the compound leaves; used by Theophrastus, 372–287 B.C.)

Holy Ghost (translation of Latin *herba angelica*)

*lus nam buadh* (herb of virtues, Gaelic)

*sløke* (simple term, Norwegian)

***Angelica venenosa*** (very poisonous)

*angelico*; hairy angelica

*notossv* [*notoss*] (Muskogee)

Europeans had long been familiar with *Angelica* when they arrived in the New World. Greeks and Romans knew the plant, and spread its fame through Europe. In Medieval Latin it was *herba angelica*, the “angelic herb,” or “Herb of the Holy Ghost.” When and by whom it was named is unknown, but Otho Brunfels (1488–1534) was the first to record the English name in 1530. It has been suggested that the plants were considered “holy” because they flower on the feast of St. Michael the Archangel (Coffey 1993).

Leonard Fuchs wrote in 1542: “It is especially effective against poisons. It wards off the contagion of raging, devastating pestilence. It protects the body from the wasting of the pestilence, they say, if only held in the mouth” (Meyer et al. 1999). Similarly, the English translation of Dodoens’s 1554 herbal said, “The rootes of *Angelica* are contrarie to all poyson.”

Not only were the plants considered medicinal, but they were cultivated in England from 1568 and used to make a confection called “Candied Angellica.” Roots have been candied in England since at least 1629 when John Parkinson wrote in his *Paradisi in Sole* (Paradise in the Sun, a play on his name) that the candied stem and roots were used “to comfort and warme a colde and weake stomach.”

When the species in Florida was discovered, the person who named it in 1793 thought it was another species of *Cicuta*. Because that is a notably poisonous plant, he called it *Cicuta venenosa*. It was not until 1943, when M.L. Fernald (1873–1950) realized that the plants were actually a distinct *Angelica*. However, by the rules of International Nomenclature, the first name given a species must be retained, even if it is erroneous. In this case, a basically nonpoisonous plant is called “venomous” (*venenosa*).

The Iroquois made a poultice of the plant to treat strained muscles and twisted joints. Moerman (1998) also records that the Iroquois ate the roots to commit suicide. However, the species is not listed as poisonous in any source I have checked (Hardin and Arena 1974, Perkins and Payne 1978, Turner and Szczawinski 1991). The plants contain furanocumarins, as do most members of the Apiaceae including celery (*Apium graveolens*) and parsnip (*Pastinaca sativa*), but there is no indication that they are likely to be fatal (Duke et al. 2001). Surely there was a misidentification of the plants in the report that Moerman used.

Small (1933) reported that the leaves of hairy angelica were used to discourage the tobacco habit. There is little other reference to *A. venenosa*, with most of the comments on *Angelica* concentrating on *A. atropurpurea* (Millspaugh 1892, Fernald et al. 1958, Foster and Duke 1990, Coffey 1993) or related species (Turner and Szczawinski 1991, Tyler 1993, Bremness 1994, Duke et al. 2001). Those other species are used in flavoring gin and liqueurs such as Benedictine and Chartreuse (Tyler 1993, Bremness 1994).

***Annona*: Pond Apples**

(From *anón*, a Hispaniolan Taino word for the fruit)

***Annona glabra*. Drawn by  
P.N.Honychurch.**

In 1514, when Gonzalo Fernández de Oviedo y Valdés arrived in Darién, Panama, he began writing what became one of the first notices of edible fruits from the Americas. His book had a chapter devoted to praise of the *guanabaná* (Oviedo [1526] 1969). This fruit was also called *anón* by the indigenous Taino of Hispaniola, and that name eventually became the genus *Annona*.

During the next 200 or so years, other species of *Annona* became known to Europeans. The *anón* was discovered by the British when physician Hans Sloane (1660–1753) arrived in Jamaica in 1687 as personal physician to the duke of Albemarle. Sloane's *Catalogus plantarum*, published in 1696, included the fruit as the sour sop. Pond apple was introduced to Europeans in 1734 by Mark Catesby. Linnaeus gave both the names used today, with sour sop becoming *A. muricata* and pond apple *A. glabra*.

Since those discoveries, it has been found that *Annona* is widespread in the Americas, and that it includes several species grown for their edible fruits. *Annona glabra* is not one of those grown for food. The fruits can be eaten, but most think they are not particularly tasty. According to one description, the fruit “has a strong smell, resembling ether, a special flavor, giving a hint of menthol” (LeCointe 1947). Be suspicious of anything described as “special.”

In Florida we know the tree and its fruit as “pond apple.” Other names also allude to a similarity with the apple, and supposedly to the animals that eat the fruits, e.g., alligator apple, *cachiman cochon* (pig *cachiman*, while *A. reticulata* is simply *cachiman*, Guadeloupe, Martinique), monkey apple, and dog apple. That origin is dubious. The names more likely mean that people were distinguishing between cultivated and wild “apples.”

Pond apple is used by people throughout its range. The soft wood has been used in rafts, as floats on fishing lines, as corks for bottles, and to hone razors (LeCointe 1947). Hence its names corkwood in English; in Spanish *corcho* (cork), or *arbol [palo] del corcho* (cork tree); in Portuguese *areticum cortiça* (cork annona, Brazil); and in French *bois flot* (cork wood, Guadeloupe, Martinique). The Maya used the same idea with *mag [mak', maak, xmaac]* (cork, Yucatan). Others call it bobwood (Belize). Some reserve the roots for making substitute corks. Amazonian Brazilians considered the wood good for carpentry, making boxes and small products (Le-Cointe 1947). The Seminoles call these trees *etotakwe [totáka]* (Creek) or *totakwî* (Mikasuki). Those names literally mean “hollow tree,” but may also allude to the spongy wood.

Other immediate and practical uses are also widespread (Morton 1981). As the seeds contain especially potent chemicals, they have been used to poison fish. However, people have been blinded by getting powder from seeds in their eyes. Similarly, seeds and leaves are insecticidal. Leaves placed in hen nests kill lice on the fowl. The bark causes dermatitis in some people. However, pond apple's greatest use is medicinal.

Medicinal traits are reflected in some common names the tree has in its range from southern Florida to Argentina. In Cuba and Hispaniola it is the *palo bobo* (crazy tree), and in Brazil *araticum do brejo [araticu du brejo]* (wizard's *Annona*, from the Tupí name for the genus, *arati'ku*, Brazil). Some of the other names have obvious meanings, and others do not: *at'p'* (Mixe, Oaxaca), *bagá* (Cuba), *catiguire* (Venezuela), *cayur [cayures]* (from *caya*, Taino, Dominican Republic), *cajuda* (Aruba, Bonaire, Curaçao), *corazón cimarron* (wild heart, Puerto Rico), *corossol sauvage* (wild annona, French Guiana), *couassol* (from *couer*, heart, French, Dominica), *guanabaná cimarrona* (wild *guanabaná*, Puerto Rico), *anonillo* (little *anón*), *mamin* (breast, French Antilles), *mamon de perro* (dog's breast).

Seeds, bark, and leaves of pond apple and its relatives contain many chemicals, including acetogenins, apomorphine alkaloids, cyclopeptides, diterpenoids, phenylpropanoid, reticuline, and (–)-*N*-methyl-lacto-daphnine (Yang et al. 1971, Haggag et al. 1981, Gupta 1995a, Chang et al. 1998, Gallardo et al. 1998, Li et al. 1998, 1999a,b, Liu et al. 1998, 1999a, b,c, Chen et al. 2000). Each compound alone has a marked impact on human physiology, and together they provide a “witches' brew” (sorry Shakespeare!) of poisons (Chávez et al. 1997). As medicines are synonymous with poisons, people have used and continue using *Annona* medicinally. Tests on these chemicals reveal tumor inhibition and other bioactivity (Warthen et al. 1969, Padmaja et al. 1995, Chávez et al. 1997, Chang et al. 1998, Liu et al. 1999a).

The acetogenins are especially potent because they inhibit the electron transport chain. In the wrong concentrations, that would inhibit oxygen availability in the body. No oxygen, no life. Theoretically, in smaller quantities, these chemicals are medicinal. Apomorphine alkaloids are largely emetics. So, if you think you have eaten something that is poisonous, you can “clean” the body with pond apple tea.

By far the most common use of pond apple is for lung and chest problems (Roig 1945). Syrup from boiled ripe fruits is used for the coughing associated with tuberculosis. A diffusion of the leaves is drunk as a beverage, often with the morning meal in Curaçao and elsewhere (Morton 1981). A stronger brew provides adults with medicine against abdominal cramps, colic, diarrhea, and dysentery (Ayensu 1981). The tea is a vermifuge (especially against hookworms), and has been used in Brazil against rheumatism (Roig

1945). Weaker draughts have been used for infant diarrhea. A decoction of fruit rind has been used for pulmonary problems in Yucatán. Leaves and flowers boiled together are used to treat liver trouble, especially jaundice, from Mexico to Argentina. However, in spite of the widespread usage, there is evidence that teas from annonas can cause symptoms resembling Parkinson's disease (Raloff 1992, Weiss 1999). So, caution is in order.

In Florida, the pond apple ranges across the state from southern St. Lucie to Manatee Counties, and south through the Keys. Elsewhere, *A. glabra* is a coastal mangrove tree; that is the reason for the names *areticum do mangue* (Brazil) and its English equivalent "mangrove annona." From Florida the trees range down the Atlantic Coast of Mexico, Middle America, and South America, and on the Pacific coast down to northern Peru. From the Americas, the species is disjunct to western Africa, where it is found in Senegal, Ghana, and southern Nigeria. Trees in Africa also have common names (Dalziel 1937); however, translations were found for only the Yóruba *âfe* (a fishing float). That name was carried by Africans taken as slaves to the Bahia region of eastern Brazil, where it is pronounced *apa* (Voeks 1997).

People also have carried the species to other parts of the world. Long ago, pond apple was introduced into Australia. Now, it has escaped there and become a pest in wetlands. So many thousands of acres of Australian wetlands are overrun by pond apple that those responsible for managing them are on the verge of despair. Pond apple, like American rabbits and prickly pears, has become a plague on that island continent. Yet, there may be hope for Australians. Some entrepreneurs think that the medicinal use may be turned to profit. They sell shampoos, soaps, and other bath items that proudly sport labels proclaiming them to contain "pond apple" extracts.

The impact of these products on human vitality is ambiguous in the language used on the labels. However, they use spin-doctoring logic—since they are "natural," they **must** be healthy. These advertising agencies and the consumers who accept their hype forget, or never knew, that strychnine, aflatoxin (from mold on peanuts; considered the most poisonous compound known), and hemlock (à la Socrates) are also perfectly "natural." So are hurricanes, tornadoes, and earthquakes. Natural does not mean good for living organisms. Nevertheless, maybe the soap companies will save Australia from invading American alien pond apples.

### *Antennaria*

(Joseph Gaertner, 1732–1791, used the Latin *antenna*, a feeler, referring to the pappus)

*antennaire* (French)

*bambagia selvatica* (wild cotton-wool, Italian)

cat's foot (England); *kattefot* (cat's paw, Norwegian); *Katzenpfötchen* (cat's paw, German)

*pied de chat* (cat foot, French)

***Antennaria plantaginifolia*.** a. Portion of plant showing rooting of creeping stem. b. Detail of staminate head, c. Female flower, d. Male flower. From Buchholtz 1968.

*wi'ti hasami'* (medicine leaves flat or stink terrapin, Catawba for *A. neglecta*)

***Antennaria plantaginifolia*** (with leaves like plantain)  
*immortelle* (immortal, alluding to the long-lasting dried flowers, Quebec)  
 lady's tobacco; woman's tobacco  
 pussy's toes [pussytoes]

Europeans were long familiar with mountain everlasting (*Antennaria dioica*) when they arrived in the New World. That medical species had a venerable history of use in Eurasia as an aromatic, bitter, vulnerary, diuretic, expectorant used to treat bronchitis, and in teas to improve milk flow in nursing women, to treat diarrhea, and for gallbladder problems (Hocking 1997). The species and its uses were discussed by Rembert Dodoens in 1616, Gaspar Bauhin in 1623, J.G.Gmelin between 1747 and 1749, and several times by Linnaeus between 1737 and 1753.

When the Europeans arrived in the New World they found similar plants that became known as *A. plantaginifolia*. They found indigenous people using that species and its relatives. The Iroquois in New England used woman's tobacco to treat leukorrhea, and as a mouthwash for toothache (Moerman 1998). The Meskwaki in Iowa used the plants to

prevent sickness in childbirth (Moerman 1998). The Cherokee gave an infusion of the plant to children for bowel problems, and to regulate menstruation in women (Hamel and Chiltoskey 1975). The Natchez used the warm infusion of the tops and roots for colds and to stop coughs (Swanton 1928a, Taylor 1940). Due to similar uses, perhaps the American species has volatile oils, resins, and phytosterols like the Eurasian plants (Hocking 1997).

### *Apios*

(Greek *apios*, a pear, from the shape of the tuberous roots)

***Apios americana*.** From Britton and Brown 1897.

#### ***Apios americana*** (of America)

*ahá caká:wa* (*ahá*, tuber, *caká:wa*, rough, Koasati); *ahe kamassa* [*ahkamassa*] (*ahe*, potato, *kamassa*, firm, Choctaw; maybe this belongs here); *ahelo'sa* (*ahe*, tuber, *losa*, black, Choctaw; maybe this belongs here, but the roots are not typically black; Bushnell 1909 wrote: "The roots are first thoroughly boiled, then mashed, and served as food"); *akkalv* (*aklowvhe*, mud, Creek); *kan-shak ahe* (*kunshak*, reed, *ahe*, tuber, Choctaw); *ocká: hî* (water tuber, Mikasuki); *vh-aklowahe* [*ahakli: wá:ha, ahakliwahi*] (*vhv*, tuber, *aklowvhe*, mud, Creek)

*blo* (Teton); *mdo* [*modo*] (Dakota); *nu* (Omaha-Ponca); *tdo* (Winnebago)

*ʔe'skame'li* (*ʔe's'ka*, root, *me'li*, black, from French *liane noire*, Tunica)

*chapelet* (Quebec)

ground-nut [groundnut]

Indian potato; potato-bean [potatobean]

*its* (Pawnee)

*ko'nan a'yip* [*ko'nen a'yip*] (*ko'nan*, potato, *a'yip*, swamp, Atakapa)

*mac-mac* (fide Core 1967)

*nu'na igatehi* (*nuna*, potato, *igatehi*, swamp dwelling, Cherokee)

*ochnenáta* (Onondaga)

*ohpenak* [*ohpen*, singular] (Strachey wrote the name in [1612] 1953 as *ouhpunnauk*, Powhatan, Virginia); *okeepenauk* (Carolina Algonquin, North Carolina); cognates are *ahpenya* (Fox); *oʔpenya* [*peneeakee*] (my potatoes, Shawnee); *ophen* (Menomini); *oppin* (my potatoes, Ojibwa); *openauk* (Carolina Algonquians); *ppan* (my groundnuts, Penobscot); akin to *múkwo'pîni* (bear potato, Potawatomi), *hópenis* [*haphniss*, *hoppenis*, *hóbbenis*, *hóbbenac*] (my potatoes, Delaware), *sagabon* (Metoac Algonquin, New York); *penninaugh* (the string of tubers, Powhatan, Virginia)

*patates en chapelet* (potatoes in rosary, Quebec)

*pénacs* (from the Algonquian name, Quebec)

*pomme de terre* (earth apple, the name now applied to the potato, *Solanum tuberosum*, Quebec)

*uli* (Cherokee)

wild bean

Along the eastern coast of Long Island in New York is a locality called Sag Harbor. Odd as it may seem, that place owes its name to a small twining legume (*Apios americana*). The harbor got its name from the Metoac Algonquin people who formerly lived there and called these legumes *sagabon* (Brooklin online 2002). The English who settled there sometimes shortened the name to *pen*, *pin*, *pon*, or *bun*, and nearby in Massachusetts they were simply *pen*. The Algonquian speakers in New England named one of the rivers *Penecook* (sing., *pen*, pl., *penak*), again because of the abundance of this vine. The word, as *pénacs*, is still occasionally used for the plants by French-speaking Canadians.

Harriot ([1590] 1972) gave us another version of the *openauk* with Algonquin groups in North Carolina. He wrote: "Openavk are a kind of roots of round forme, some of the bigness of walnuts, some far greater, which are found in moist & marshy grounds growing many together one by another in ropes, or as thogh they were fastened with a string. Being boiled or sodden they are very good meat."

In [1612] 1953 Strachey recorded the Powhatan name as *ouhpunnauk*, and Siebert (1975) has it phoenetically as *ohpen*, with plural as *ohpenak*. Related words are *hópenis* (Delaware), *ahpenya* (Fox), *ophen* (Menomini), *oppin* (Ojibwa), and *ppan* (Penobscot). Edgar (1891) gave the Shawnee name as *peneeakee*, but Siebert (1975) wrote *oʔpenya*.

Core (1967) gave yet another story. He says that the plant is *mac-mac* but declines to give his source or mention the tribe. Probably that is the same as the tribe Micmac, Algonquian people who live in and around Nova Scotia. There is a triploid race growing in the area that these people surely cultivated (Bruneau and Anderson 1988).

In English, the plant usually is called Indian potato, although some call it potato bean, wild bean, or even groundnut. The name groundnut has confused people from the early settlement times until the present because of confusion with another "ground nut" more often called "peanut" (*Arachis hypogaea*) in American English. The Latin name of the Indian potato groundnut is *Apios americana*, a name it received in 1759. However, that binomial took almost a century to come into its modern form.

The first scientific mention of what we now call Indian potato was made by Jacques Philippe Cornut (1626–1651). In discussing plants in Canada, Cornut called them *Apios americana*. Shortly afterward, Robert Morrison (1620–1683) again mentioned the plants

in his book *Plantarum historiae universalis* (Universal History of Plants). Although Cornut had named the vines, Morrison called these American vines *Astragalus perennis spicatis americanus*, *scandens caulibus*, *radice tuberosa* (the perennial American *Astragalus* with a spike, climbing stem, and tuberous root). When Linnaeus was studying the plants of the world, he examined the plants and specimens collected by Clayton in Virginia. Linnaeus decided that they were better called *Glycine apios*, combining names from several of the people who had studied the plants before him. He and Cornut had used the Greek word *apios*. German botanist Friedrich Casimir Medikus (1736–1808) disagreed that this species was a *Glycine*. He thought that the species should be in its own genus called *Apios*, and in 1787 he proposed the name we now use—*Apios americana*.

Not only did the Latin name vary, but several linguistic groups in North America also had their own names for the plants. The second oldest recorded American name for the plant seems to be *hopniss* or *hapniss*. That word was in use in New Jersey by the Delaware and Swedes when Linnaeus's student Peter Kalm visited in the 1700s (Kalm [1753–1761] 1972). The Delaware's neighbors, the Onondaga, called the plant *ochnenáta* (Zeisberger and Horsford 1887). After the introduction of the turnip (*Brassica rapa*), it became known as *hóbbenis* and *otechra*, in a new application of old names.

The Cherokee in the Carolinas called it *ulí*, a simple generic word for tubers (Hamel and Chiltoskey 1975) or *nu'na igatehi*, swamp dwelling potato (Mooney 1885–1886). Even though the Cherokee and Seminoles speak linguistically distant languages, an apparently cognate word for tuber was also applied by the Seminoles. Creek speakers call the vines *ahakli*: *wa:ha*, and their relatives call it *ocká:hî* (Mikasuki). That the plant was important to the Seminoles is recorded in the name of a village, originally *ahapopka* (root-eating place, Creek), now Lake Apopka, that once stood near the head of the Oklawaha River (Orange County). Their relatives the Choctaw say *kanshak ahe*. People farther north and west called the plants *blo* (Teton), *its* (Pawnee), *mdo* [*modo*] (Dakota), *nu* (Omaha-Ponca), or *tdo* (Winnebago) (Gilmore 1919). These simple words probably simply mean “tuber” or “root.”

At first, French speakers, especially those in Canada, called this plant *pomme de terre*, the name now applied to the potato (*Solanum tuberosum*). About the same time they said *patates en chapelet*, or sometimes simply *chapelet*, because of the string of tubers on a root. French explorer Le Jeune said that Indians eat “a root...that our French people call ‘rosary’ [*chapelet*], because it is distinguished by tubers in the form of beads” (Vogel 1970). At Port Royal, Nova Scotia, the French troupes with Charles Biencourt de Saint-Just (1591-ca. 1623) scattered about the woods and shores digging these roots for food in 1613 (Hedrick 1919).

An indication of the importance of this wild food is the extent to which it was recorded in the literature on indigenous Americans (Smith 1933, Yanovsky 1936, Moerman 1998). Among the people either boiling or roasting the tubers, or substituting the seeds for pinto beans, were the Cherokee (western North Carolina and northeastern Georgia), Cheyenne (Montana), Dakota (Montana, North and South Dakota, Nebraska, Minnesota), Delaware (New Jersey and vicinity), Huron (southern Ontario and Michigan), Menomini (Wisconsin), Meskwaki (Iowa), Mohegan (Connecticut), Ojibwa (upper Mid-west and southern Ontario), Omaha (Nebraska), Pawnee (upper Missouri River region of Nebraska), Ponca (Nebraska and South Dakota), Potawatomi (Wisconsin), Creek/Seminole (Georgia and Florida), and Winnebago (Wisconsin). John

Bartram told Peter Kalm ([1753–1761] 1972) that the indigenous people who lived more inland not only ate the roots, “but likewise take the pease which lie in the pods of this plant, and prepare them like common pease.”

The plant itself ranges even more widely than the people for whom we have records of uses. We know that *Apios* grows from Quebec to Minnesota and North Dakota to Montana, and south to north central Colorado down to Texas and east to Florida. Thus, people living in much of its range appear to have left no record of having used it. One example of absence of historical records is Florida. There, the pollen of *Apios* is known from Glades Indian sites that predate Europeans (Hogan 1978). So, we do have evidence that the original Florida people used the plants.

Some consider Indian potato to be held in highest esteem as food by Americans. Even many Europeans wrote of it with enthusiasm. Capt. John Smith, speaking of Virginia in 1626, wrote of “Ground nuts as big as Egges, and as good as Potatoes, and 40 on a string not two inches under ground.” There was supposed to be a 1654 town law among the Pilgrims that ordered an indigenous person to be put in stocks if discovered digging groundnuts on English land. A second offense was to be punished by whipping (Fernald et al. 1958). There is even evidence that the species was cultivated outside its normal range. Indeed, the northern plants are sterile triploids that would not survive if people did not propagate them (Bruneau and Anderson 1988). Requiring cultivation speaks well for their former reputation as a starch source in that region. Williams ([1837] 1962) wrote that the “Seminole raised great quantities for food.”

Although many natives and the first European settlers in North America used the roots for food, not everyone was complimentary about it. Even some indigenous tribes considered it famine food. According to a study done in 1954, the Huron ate the roots with acorns during famines. Many groups saved the roots to use during winter. Raw roots have been described as “tough, with a very viscid, milky juice, but of a pleasant sweetish, turnip-like taste” (Fernald et al. 1958). Reportedly, the young tubers eaten raw leave a rubber-like coating on the teeth. Most of the recorded uses overcame these problems by roasting or boiling the tubers and then drying them. Some ground them for later use like flour.

Typical of the American paranoic approach to the world, today one group of researchers is trying to reintroduce the Indian potato as a crop (Blackmon and Reynolds 1986, Reynolds et al. 1990), while another is looking for chemicals to destroy it as a weed (Devlin and Deubert 1982). Still other investigators are finding that this wild plant has healthy chemicals that could be incorporated into modern diets (Wilson et al. 1987, Krishnan 1998, Mazur et al. 1998). Among other chemicals, the roots contain genistein, an anticarcinogenic compound (Krishnan 1998), isoflavonoids and lignans (Mazur et al. 1998), and amino acids (Wilson et al. 1987).

These vines are not that common in southern Florida, but they can be found growing on stream banks and in other swampy areas. When they are found, a lucky person will find them in flower. The blossoms appear in the summer, they are an unusual purple color, and the clusters are often tucked back under the foliage. By carefully watching, a person can find the pollinators—flies (Westerkamp and Paul 1993). That may not help their reputation as a food plant, but fly-flowers are comparatively uncommon in Florida.

*Apocynum*

(From Greek *apokynon*, composed of *apo*, away, and *kyon*, a dog, for a plant supposedly poisonous to dogs)

*Apocynum cannabinum*. a. Seed pods.  
b. Section of stems and rootstock. c.  
Upper part of stem with leaves and  
flowers, d. Seed with attached coma.  
From Buchholtz 1968.

*Apocynum cannabinum* (hemp, because of its use for fibers)

American [-Indian] hemp [American Indian hemp]

American ipecacuanha (“ipecacuanha” from Tupí-Guaraní *ipe-kaa-guéne*, creeping plant causing vomiting, 1682, originally *Cephaelis*)

*beba'mokodjibika'gisin* (bear root, found here and there, Ojibwa)

bowman's root (from use of fibers to make bowstrings)

Choctaw root [Choctawroot] (the Choctaw were people living in Mississippi, Alabama, and Louisiana; originally spelled *Chacta*, in 1675, and later *Chahta*)

[hairy, hemp, prairie, smooth, willow] dogbane [dog's bane] (a translation of the Greek); *Hunds-gift* (dog's poison, German)

dropsy root (from use to treat dropsy, by ca. A.D. 1290 and Middle English *ydropsy*, now “hydropsy,” where liquid leaks from the venous system into the surrounding tissues)

*gatuñ'lati* (wild hemp, Cherokee; there is a locality in Fannin County, Georgia called *Gatun'iti'yi*, “Hemp place”)

*'gho-la [ghola]* (Kiowa)

[blind, Canada, Canadian, Indian] hemp (from Old English *haenep*, which was derived from Old Teutonic *hanapiz*; that word was cognate with Greek *kannabis*, and Latin *cannabis*; originally used ca. A.D. 1000 for what is now *Cannabis saliva*, although later used for New World plants); *canadische Henf* (Canadian hemp, German); *chanvre du Canada* (Canadian hemp, French); General Marion's hemp (so called because it was a favorite remedy of General Frances Marion, 1732?-1795, the “Swamp Fox” of the Revolutionary War, South Carolina); *wilskt hampa* (Indian hemp, Swedish)

*herbe à la puce* (flea herb, particularly applied to *A. androsaemifolium*, Quebec)

*houatte* (probably a variation of *ouate*, fiber used in stuffing or quilting, Quebec)

Indian physic (from Middle English *fisike*, in English since A.D. 1297, in turn from Latin *physica*, the art of healing with plant products)

kendyr (English?)

*lechuguilla* (little lettuce, New Mexico)

*mukosaka'sakuk* (sharp podded weed, Meskwaki); *mukoseki' ashikiki* (like a milk weed, Meskwaki)

*nape'oi'lekiyapi* (to burn it in the hand, referring to the fact that the fluffy seeds can be placed in the hand, lit, and burned without hurting the hand, Lakota)

*nuxa-pist* (little blanket, Blackfeet)

old amy root (South Carolina)

*pimenaw* (given by Strachey [1612] 1953 as *pemenaw*, and in Spanish as *pemmenáu*; Siebert 1975 interprets it as “hemp dogbane fiber or plant”; Willoughby 1907 said Byrd [1728] 1980 called it “silk grass” and that it had “stems about as large as the little finger”; see also *Yucca*)

rheumatism weed

snakes' milk

wormroot (supposedly translated from Penobscot name)

Linnaeus coined the species name in 1753, and thus confirmed the plants' use as a fiber source. He knew the plants from both Canada and Virginia, and could have learned about it from either place because people through its range extracted the fibers. One of the first reports of the plants being used in historic times was by David P. de Vries in 1642, but it is unlikely that Linnaeus saw that record (Vogel 1970). Peter Kalm also reported it was used by indigenous people and Swedish settlers in 1750 in Pennsylvania and New Jersey.

Kalm ([1753–1761] 1972) also published in 1753 that: “The people prepared the stalks of this plant, in the same manner as we prepare those of hemp or flax. It was spun, and

several kinds of stuffs were woven from it. The savages are said to have had the art of making bags, fishing-nets, and the like, for many centuries together, before the arrival of the *Europeans*.” Later, he wrote: “On my journey through the country of the Iroquese [Iroquois], I saw the women employed in manufacturing this hemp. They made use neither of spinning-wheels nor distaffs, but rolled the filaments on their bare thighs, and made thread and strings of them, which they dyed red, yellow, black, &c. and afterwards worked them into stuffs, with a great deal of ingenuity.” Later he wrote of a hempen rope 14 yards long that the Swedes purchased from the Iroquois for a piece of bread.

This is the same use that Strachey recorded in [1612] 1953 with *peminak* (rope), *pemunakqweraneind* (twined thread), *peyminakoó* (thread), *pemanakaon* (cord or small line or a thread), and *pemunkuan* (rope or cord) (Harrington 1955, Siebert 1975). The words, and doubtless the plants, occur in cognates for thread, including *piminahkwan* (Cree), *pimenahkwan* (Menomini), *piminakkwan* (Ojibwa), and *piminikwa* (Shawnee).

Gilmore (1931) reported that fibers of *Apocynum cannabinum* had been used by the Ozark Bluff-Dwellers in Arkansas to make twine and cords. Later, Jones (1936) identified the fibers in textiles and cords at the rock shelter at Menifee County, Kentucky. Whitford (1941) found both Adena and Hopwellian woven fabrics made from Indian hemp. He also found its fibers in Arkansas cords, Fox and Sauk bags, a fish net used by the Nanticoke, and an Iroquois burden strap.

As a medicine, apparently one of the oldest names for these plants in the southeastern United States is “Choctaw root.” These people constituted the largest group in the southeast, with the exception of the Creek Confederacy (Swanton 1946). They had first been encountered by the Spanish expeditions through the area, including de Soto (Swanton 1946), and previously were known as the *Pansfalallya* [*Apafalaya*, hence Pensacola], long hair, because the men let their hair grow full length, unlike the surrounding people. Constantine Rafinesque reported in 1828: “This is a very active plant, highly valued by the Southern Indians. It is tonic, emetic, alterative and antisyphilitic. The root is the most powerful part; but it must be used fresh, since time diminishes or destroys its power ... it acts as an emetic, equal to Ipecacuana; in smaller doses, it is a tonic, useful in dyspepsias and fevers. The Chicksaws and Choctaw Nations employ it in syphilis and considered it as specific.”

Perhaps it was plants from the southeast about which Porcher (1863) wrote: “This plant has been proved by Prof. Thouin, of Paris, to possess a stronger fibre than that of hemp; and it is used by the American Indians for making cordage, fishing nets, and coarse cloth.”

People from the Iroquois, Menomini, and Potawatomi of the northeast, to the Okanagan-Coville of the Canada, Washington border, and south to Cahuilla of southern California and adjacent Baja California Norte used the plants for medicine (Smith 1933, Moerman 1998). Oddly, there seem to be no records south of the Cherokee and Kiowa (Moerman 1998). There is a similar gap for the related *A. androsaemifolium* that covers much the same range. Surely, this reflects absence of data and not lack of use. As some of the names indicate, the plants have been used to treat dropsy, rheumatism, worms, constipation, pox, uterine obstructions, Bright’s disease, asthma, wounds, diarrhea, biliousness, sore mother’s breasts, and stomachache (Moerman 1998).

The root bark is an emetic and cardiac stimulant (Mabberley 1997). However, it is poisonous to animals such as cats, dogs, and livestock due to the presence of resins and

cardiac glycosides, including cymarín, apocannoside, cyanocannoside, apocynamarín, and others (Turner and Szczawinski 1991). As little as one-half ounce of the plant ingested by livestock may kill a large farm animal such as a cow (Foster and Caras 1994). While sickness and death have been reported among humans who used it in medicine (Diggs et al. 1999), Foster and Caras (1994), and Turner and Szczawinski (1991) say there are no records of humans having died after using it.

The plant is also used as a brown or black dye (Porcher 1863).

### *Aquilegia*

(Derived by some from *aquila*, the eagle, from resemblance of the spurs to the claws; by others from *aqua*, water, *legere*, to collect, from the nectar at the base of the hollow spur)

*Akelei* (Dutch, German); *akeleie* (Norwegian, dedicated to the goddess Frigg)

*amor nascosto* (hidden love, Italian)

*ancolie* [*anquellie*, *angorie*] (in use by 1325; borrowed from medieval Latin *aquilea* derived from Latin *aquilegus*, “that which collects water,” because of the small cavities in the flower; later, the name was brought closer to Latin *aquila*. The initial nasal vowel is probably influenced by *melancolie*, justified by the position of the flowers; since the 15th century, *ancolie* has been the symbol of sorrow, French); *aquileña* (Spanish)

columbine (from French *colombine*, based on Latin *columbina*, dove-like, from the appearance of the five flower spurs resembling a cluster of doves)

*erva pombinha* (little dove herb, Portuguese); *lus a'chalmain* (dove herb, Gaelic)

*Aquilegia canadensis* (of Canada)

akeley (surely from French *ancolie*); *ancolie* (Quebec)

bells (Ohio); [red, rock]-bells

cluckies (Nova Scotia)

[red, wild] columbine

culverwort

*gants de Notre-Dame* (Mary's gloves, Quebec)

honey-horns; honeysuckle (a name usually applied to *Lonicera*, but used for this in Illinois, Massachusetts, New Hampshire, Wisconsin)

*inubthon-kithe-sabe-hi* (black perfume plant, *inubthon*, fragrant, *kithe*, to make, *sabe*, black, *hi*, plant, Omaha-Ponca); *mon'-bi-xon ça-be* (*mon'-bi-xon*, perfume, *ça-be*, black, to distinguish it from other *mon'-bi-xon*, or other aromatic seeds used for perfume, Osage)

jacket-and-breeches; Jack-in-trowsers (Massachusetts)

meeting houses (New England)

rock-lily (New Hampshire)

*skalikatit* [*skarikatit*] (*skali*, seed, *katit*, black, Pawnee)

Linnaeus knew only this single American species and only two European kinds, although there are 19 species native to Europe (Mabberley 1997). Gaspar Bauhin was one of the first Europeans to use the name *Aquilegia* in 1623. Neither he nor Linnaeus explained its etymology, and the meaning is still debated. Judging from the Gaelic, Portuguese, and Old Latin names, the plants were probably considered more like doves than eagles. Frenchman Jacques Philippe Cornut (1626–1651) seems to have been the first European to discuss this American *A. canadensis* in his *Canadensium plantarum* (Canadian plants) of 1635.

The Cherokee used an infusion of the plant for diarrhea and heart trouble (Hamel and Chiltoskey 1975). Otherwise, records are from farther north. The Iroquois made a compound infusion of the plants with others to treat poison ivy and itch and for kidney problems (Moerman 1998). Similarly, the Meskwaki, Ojibwa, Omaha, Pawnee, and Ponca used the plant in a variety of ways (Gilmore 1919, Moerman 1998).

### *Aralia*

(From French-Canadian *aralie*, the original specimens having been sent by the Quebec physician Michel Sarrasin de l'Étang, 1659–1734, to J.P. Tournefort, 1656–1708, under that name)

*Aralia spinosa*. From Sargent 1905.

#### *Aralia spinosa* (with thorns or spines)

- American angelica tree
- devil's walking stick [devil's walkingstick] (because of the spiny trunk)
- Hercules' club
- ittohalokpá* (*ittó*, tree, *halókpa*, sharp, Koasati)
- pick-tree
- pigeon-tree (because birds eat the fruits)
- prickly ash (comparison of the leaves with *Fraxinus*); prickly elder (comparison of the leaves with *Sambucus*)
- toothache-tree (from analgesic compounds)

Leonard Plukenet (1641–1706) published on *Aralia spinosa* in 1696, and a year later Jan Commelin (1629–1692) wrote about them. Commelin had them in cultivation in

Amsterdam, and presumably Plukenet had them growing in London. Linnaeus knew this species, plus one from China and two others from the New World. There are now about 36 species in the bicentric genus, with species in North America and east Asia (Mabberley 1997).

The Creeks used the root to stop internal bleeding; the Choctaw applied a poultice to swollen leg veins; and the Koasati put a cold infusion of the roots on sore eyes (Taylor 1940). The Choctaw also used *A. racemosa* root (*tally apola*, maybe *tali*, the end, and *apoli*, to pass through slowly) as a stimulant and expectorant (Campbell 1951).

Neighbors of the Muskogean people, the Cherokee, used *A. spinosa* to treat rheumatism and flatulence, in a salve for persistent sores, as a diaphoretic, a strong emetic, a tonic, to treat toothache, and against venereal disease (Hamel and Chiltoskey 1975). The Rappahannock of Virginia also made a salve to treat boils and sores, and used it as a remedy for fever (Moerman 1998).

### ***Ardisia*: Marlberry**

(Name based on Greek, *ardis*, a point or arrow point, referring to the anthers)

***Ardisia escallonioides*. Drawn by  
P.N.Honychurch.**

Hammocks (West Indian hardwood forests) along southern Florida coasts have shrubs in them that people call marlberry. Botanists call the plants *Ardisia escallonioides*, a name applied to it in 1831.

In Florida and in the Bahamas, this shrub is sometimes also called dogberry. Names that have “dog” attached to them really have nothing to do with canines, but simply mean “wild.” In most cases, the wild plant reminds people of something that is “tame” and they need a way to distinguish one from the other.

Fruits on these shrubs often remind people of blackberries (*morita*, Oaxaca), cherries, or other fruits. More people seem to think of it as a cherry, and formerly *Ardisia* was

called “cherry” in Florida. That name is also applied by people throughout much of Mexico and the Caribbean. For example, our species is called *capulín* (cherry, San Luis Potosí), *capulín agrio* (sour cherry, San Luis Potosí), *capulín de pajaró* (bird cherry, Morelos), or *yagalancito* (*yagalan*, cherry or *Prunus*, *cito*, little, Zapotec, Oaxaca). In Panama, any species is likely to be called *iskarmas* (Cuna) or in Spanish *uvito* (little grape). In Martinique, they also compare it with grapes, and other species are called *bois raisin* (raisin tree). The Asian exotic *A. elliptica* (often called *A. solanacea*) is called “blackberry” in Jamaica. Some of the Puerto Rican species are called *mameyuelo* (little mamey). The *mamey* is the Taino name of *Mammea americana* (Sapotaceae), a fruit prized throughout the Greater Antilles.

As all these names suggest, the fruit is edible. Some think it good, or they would not compare it with blackberries, grapes, and raisins. Others think it is “unappealing” (Morton 1968b). Perhaps how good or bad it tastes depends on how hungry a person is. In Panama the Bayano Cuna use the plants medicinally, and stain their bodies with the berries (Duke 1972). Most literature mentions only the edible fruits and useful wood, but people in Panama and Mexico have medical usage for these plants. Other species also have medical applications (Hocking 1997).

Among the species used are American and Asian plants. More information is available on the Old World species than the American. For example, *A. crenata*, a Malesian species cultivated in Florida, is mixed with other plants in a tea to treat bruises, broken bones, and sprains. Application is both external and internal. From India through China, southeastern Asia to Japan, *A. crispa* roots are used to treat fevers, excessive salivation, to heal injuries, and as a diuretic. In Indochina, *A. isoraefolia* fruits are boiled as part of a vapor inhaled to stop pain in decayed teeth. Although several others are used, the most often noted is *A. japonica*, whose root decoction is used to treat influenza, to serve as a carminative, and as a poison antidote. The leafy shoots are made into a decoction used to stop coughs and uterine bleeding. Perhaps our species should be investigated further.

Several species are known to have a number of chemicals including anthocyanins, ardisicrenosides, glycosides, quinones, resorcinol, saponins, and triterpenoid saponins. Some of these compounds have been named ardisin, ardisinol-I, ardisinol-II, 2-hydroxy-5-methoxy-3-pentadecenyl-benzoquinone, bergenin, embelin, ilexol, myricitrin, quercitrin, and rapanone and (Podimuang et al. 1971, Ahmad et al. 1977, Jansakul et al. 1987, Tian et al. 1987, Wang et al. 1992, Jia et al. 1994, Baldini et al. 1995, Nguyen et al. 1996, Piacente et al. 1996, Horgen et al. 1997, Huang et al. 2000). Laboratory experiments show that some of the extracts have antiviral activity, including human immunodeficiency virus and certain kinds of cancer.

A number of people have used the leaves as tobacco substitutes, or at least in mixtures. The Miccosukee called the plants *akcomakáhka:pló:cí* (black tobacco seasoning tree). Their Seminole relatives the Creeks call it *hici:apa:kalásti* (*hece*, tobacco, *vpakv*, seasoning, *lastv*, taste). Although Sturtevant (1955) recorded them as mixing the “leaves with tobacco to extend it,” the common name suggests a more complicated purpose. Several tribes throughout the Americas mixed other plants with their tobacco for different reasons, including changing the flavor, but particularly for weakening a strong mixture. The Seminoles probably did that and simply did not reveal the information to Sturtevant. According to some individuals now on the reservation, they withheld many of their

customs from Sturtevant. In Martinique, another species is called *bois chique* (tobacco tree). Perhaps smoking of the leaves was more widespread in the past.

Throughout their ranges, several species provide useful wood. The Miccosukee used the plants to make arrows, and as sticks for roasting meat. They also ate the berries as did other people.

The name *pejté* (Huastec, San Luis Potosí) has been reported for this species, although Alcorn (1984) did not find it being used. Instead, she found her informants calling the plants *pelat puchun*, meaning dove legs. Children ate the fruits, but adults mixed them with *atole* for food. The root and shoots were boiled with some other plants (*Malvaviscus arboreus*, *Paullinia tomentosa*, and *Cirsium* sp.), and used against diarrhea, stomach trouble, and vomiting.

The Maya in Yucatán have several names for *A. escallonioides*, but none of them suggests medical usage. Their application seems to be more immediately practical. They call the plants *ch'onche'* (*ch'on*, vulture, *che'*, tree, or tree where vultures sit), *sak'hoktub* [*sak-hok-tub*, *zachoclub*] (*sak*, white, *hok*, pull out, *tub*, around, probably meaning white tree that grows on the margins of planted fields [*maíz*]), and *sak'loobche'* (*sak'*, white, *loob*, to make storage bins, *che'*, tree). That last name is associated with use in creating storage bins where they keep their seeds for planting next season.

These same people also call the plants *xook* (chair, Maya, Yucatán). Presumably, they use the wood for making seats, although that too may be an allusion to the vultures sitting on them. A version that remains unclear is *xooknum* [*xook gum* by error]. The word *num* means spines that serve as pins, incapable, slow, or difficult. None of these makes sense to José Luis Tapia or me.

Some other names for marlberry have not been translated. These are *chaquis* (maybe based on *chaqué*, a kind of frock coat, Morelos), *guitumbillo* [*huitumbillo*, *huitumbio*] (Chiapas), *hullaba* (Belize), *residan* (Belize), and *mantákihui* (Totonac, Veracruz).

Flowers on these plants fool some people when they first see them into thinking that they are members of the Solanaceae. However, closer examination reveals that they are in the Myrsinaceae. The anthers are distinctive in this genus, and led Olaf Peter Swartz (1760–1818) to coin the name *Ardisia* in 1788. The flowers are fragrant and attract a number of pollinating insects (Pascarella 1997). There is also a close association between the species and a particular group of moths (Pascarella 1996).

When I first arrived in Florida, there was a popular commercial on billboards and elsewhere advertising Marlboro cigarettes. There was a tough-looking cowboy with a cigarette dangling from his mouth and the slogan, “This is Marlboro country.” One of my colleagues decided to use that to his advantage to help people remember the name of the marlberry. He would take students into hammocks, point out the plants, and remark that “This is marlberry country.”

That name “marlberry” always struck me as odd, because I did not find the plants growing on marl, a particular soil type where clay is mixed with calcium carbonate. Some places in the southern end of the state have large deposits of marl that were created when the sea levels were higher during the geologic past. Other places have accumulations that are more recent because the process is ongoing, marl being deposited by accretion of calcium carbonate crystals on cyanobacteria (blue-green algae-like bacteria). The process continues in the wet summers when water gathers in lower areas.

Few organisms can grow in marl, as it is nutrient poor and a harsh environment, either waterlogged or brick-hard when dry. It is only when marl becomes mixed with organic detritus that plants can grow in it. So, I wondered, why do people call *Ardisia* marlberry? Finally, I came across the probable answer. The word “marl” not only refers to the soil type, but it has evolved as a colloquialism. It seems that “marl” has become a contraction of “marvel.” Historically, this abbreviation appeared in the literature in the early 1600s. The earliest example was written by Ben Johnson in 1609. In a sentence dealing with the collar and cuffs on a shirt, he noted: “‘Tis mar’l you ha ‘hem on now” (It is a marvel that you have them on now).

That is probably also the origin of the name “marlberry” as a contraction of “marvel berry.” Perhaps the early settlers in the Bahamas and Florida were pleased with the berries and thought them a “marvel,” but more likely they thought they looked like “marvels” (marbles). I grew up with people who pronounced “marble” as “marvel.” So, our marlberry is really a “marble berry.”

### ***Argusia*: Sea Lavender**

(From Greek *Argos*, the hundred-eyed keeper of Io)

***Argusia gnaphaloides*. Drawn by  
P.N.Honychurch.**

Sea lavender (*Argusia gnaphaloides*) is a gray shrub that grows on the beaches of most of the New World tropics, through southern Florida, Bermuda, the Bahamas, West Indies, Yucatan, Mesoamerica, and Venezuela. Indeed, the species name *gnaphaloides* means that it resembles the white-gray plants in the genus *Gnaphalium* (Asteraceae). The plant was common on beaches throughout its range before people began developing the coastal areas for homes, businesses, and recreation. Moreover, it has white flowers, not lavender.

Before understanding why people call Florida's gray plant "lavender," it must be understood that the flower, leaf, and stem color was not the immediate source of the common name. "Lavender" is a comparison with an Old World mint. To Europeans, the "lavender" plant is *Lavandula*, a fragrant mint native to the Mediterranean, the Middle East, and India, and used for hundreds, if not thousands, of years. The word came to English through Middle English (*lavandre*), which in turn came from Middle Latin (*lavandula*). These words for the plants have all been used since at least the 1200s. They are perhaps all based on Latin *lavare* (to wash or bathe). Yet, it is possibly a corruption of the original word Latin *lividus*, blue or bluish, which was mispronounced. Perhaps it is also possible confusion or comparison with "bluing," a colloidal solution based on ferric hexacyanoferrate that is still sometimes used to make washed clothes brighter. Either way, since the Middle Ages, *lavandula* has indicated specific blue-flowered mints in Latin, Italian (*lavanda*), Spanish, and French (*lavande*).

Portuguese speakers say *alfazema*, which is surely cognate with *alhucema*, the alternate Spanish name for the plants. These seemingly anomalous words for the same plants are actually based on Arabic *al-khuzamâ* (the pleasant-scented one).

Still, since at least the Middle Ages the common name "lavender" has indicated the color of the flowers, and not the herbage. The word has been used so long in American English for a color that now few think of the application to the whole plant. Yet, the European aromatic herb was in the minds of newcomers to the New World where they encountered a similar plant growing beside the sea. So, what could be more natural than to call it "sea lavender" (Bermuda through Florida to Jamaica and Virgin Islands), "bay lavender" (Bahamas, Puerto Rico, Virgin Islands), or "white lavendel" (Dutch Antilles) in English, and *alhucema de costa* (coastal lavender) in Spanish. Others thought it better to call this aromatic new plant after some other mint. So, it became *salvia marina* (marine sage, Cuba), *romarin* (rosemary, Lesser Antilles), *romarin blanc bord-de-mer* (white seaside rosemary, Lesser Antilles), or *incienso de costa* (coastal incense, Cuba), *incienso de marino* (marine incense), *incienso de playa* (beach incense), or even *balsamillo* (little balsam, Cuba).

Plants frequently have dead leaves clinging to the lower branches, and these apparently looked like tobacco to some of the people examining them. Since the tobacco (*Nicotiana*, Solanaceae) was not a plant familiar to people in the Old World before arriving in the Caribbean to see the Caribs and Arawaks using it, perhaps names alluding to this American plant came from indigenous people. One of the first places Europeans settled was the island of Hispaniola, and there the sea lavender is called *herbe à chiques* (tobacco herb, Dominican Republic), *liane à chiques* (tobacco vine, Dominican Republic), *liane chiques* (tobacco vine, Dominican Republic), *racine chiques* (tobacco root, Dominican Republic). Nearby, and reaching to the Netherland Antilles off Venezuela, it is *tabaako die piskadoo* or *tabaco de pesadores* (fisherman's tobacco), *tabacón* (big tobacco), *tabacón piscador* (fisherman's tobacco), *tabacu di pescado*

(fisherman's tobacco), *vesserstabak* (fisherman's tobacco, Dutch Antilles). If people actually used these plants as a tobacco substitute, I have found no evidence of it. Indeed, with the other uses that they have, it seems doubtful that they were smoked or chewed.

Medicinal uses are those most often recorded for sea lavender, and a variety of common names supports those observations. In the Dominican Republic they are called *herbe à malingres* (herb for the sickly), or *té marino* (marine tea). Elsewhere they are *té del mar* (sea tea, Puerto Rico), *temporana* (the early one, Puerto Rico), or *bois de lance noir* (black lance bush, Lesser Antilles), also suggesting medicinal uses. The name iodine bush (Morton 1981) is either a misapplication or mistaken identity, because that is a name usually applied to *Allenrolfea occidentalis* (Amaranthaceae). Either way, it suggests medical use.

Like its relative chiggery grapes (*Tournefortia hirsutissima*), this seaside plant has been used against those bothersome little spiders. It is called *nigua* (chigger), or *nigua de playa* (beach chigger) in both Puerto Rico and the Dominican Republic.

Several of the names associate the plants with animals. Some of these associations are obvious, and others are not. For example, the name *crête coq* (rooster's comb, Dominican Republic) is a common theme in the family (Boraginaceae). The comparison is made because of the curving inflorescence that reminds people of the comb on the rooster's head. A little more obtuse is *yerba cotorra* (parakeet's herb, Puerto Rico), but it probably means that these small Psittacidae eat the fruits or drink nectar from the flowers. Since both occur on beaches, the name crab bush (Virgin Islands) seems straightforward. Totally incomprehensible to me is *loup marine* (sea wolf, Lesser Antilles).

The Mayan name *ts'its ik maay* [*sicimay*, *siki-may*] (*ts'its ik*, strong, *maay*, perfume, Yucatán) is given because early in the morning, before the sun gets hot, the plant is at first pleasantly fragrant. Later the odor becomes unpleasant. Unfortunately, we do not know the meaning of the name *kokorobana*, used in Aruba, Bonaire, and Curaçao, but it resembles indigenous words in northern South America.

The scientific name in most modern literature for sea lavender is *A. gnaphaloides*, but it varies in different sources. For a short while it was called either *Mallotonia gnaphaloides* or *Messerschmidia gnaphalodes*, but the name most commonly used is *Tournefortia gnaphaloides*. This variation is distressing to everyone, but results from varying opinions about how different groups of species must be from others to be recognized at generic rank. The genus *Tournefortia* comprises largely twining or climbing plants, and that caused some people to exclude these erect shrubs. Other traits for the genus are fruits that are corky outside and fleshy leaves, but the habit is most easily noted. The genus *Argusia* was proposed for these species in 1760 by Georg Rudolf Boehmer, a German botanist in Leipzig. The species serving as the focal point for this genus concept is *A. sibirica*, originally described by Linnaeus as *T. sibirica*. Therefore, plants on opposite sides of the world have been united into the genus as discussed here. Since the fruits of most *Tournefortia* are fleshy and adapted for animal dispersal, some think that the corky fruit of *Argusia*, adapted for floating and water dispersal, is simply a convergent adaptation in distant species within a single genus.

Sea lavender, like its namesake *Lavendula*, has aromatic foliage and blossoms. Honeybees visit the flowers and produce honey in areas where the plants still thrive. Yet, while people scent their clothes and foods with *Lavandula*, no such use has been made of sea lavender, nor is such a use likely. Indeed, Morton (1968) tells us that when leaves are

burned in the house it drives out fleas. Petersen (1974) confirms at least that the plant is used as an insecticide, but gives no further details. Both these authors and others indicate that the stems and leaves are used in “bush baths” to clean wounds and ripen boils and to treat other skin problems. As a footbath it is used to treat stiff legs. Leaves also are washed and held in the mouth to alleviate oral inflammations. Some localities in the Caribbean have prominent places among the herb vendors for sea lavender branches. In Curaçao, some individuals take a weak infusion of the leafy twigs each morning, with sugar, as a tonic and stomachic. Supposedly, this beverage also expels gravel (kidney stones) from the bladder and kidneys. One of the common uses among men in at least the Dutch Antilles is against venereal diseases. The leafy branches are mixed with *Stemodia maritima* and Epsom salts and drunk to relieve those problems. As the plants are listed among those that are diuretic, they may give temporary relief. It might even be that the Puerto Rican name *temporana* is an allusion to that temporary “fix.” A decoction of leafy twigs is used as an antipyretic (Morton 1981, Hocking 1991), and several sources indicate that the plants have been used as an emmenagogue. Some believe that a decoction of the plants is an antidote for fish poisoning. Cubans even use a decoction against catarrh.

Perhaps the spotty literature on the species is due to the reluctance by some people to admit that they use the plants. Morton (1981) found women in the Dutch Antilles either reluctantly confessing that they use the plants, or at least crossing themselves before admitting it. That reluctance was because the plants are also used to induce abortion. Those people to whom Morton spoke were Catholics and in admitting use of the plant they ran the risk that they would be suspected of that practice. However, the same decoction in weaker doses is said to ease delivery for pregnant women (Morton 1968a).

### ***Arisaema*: Jack-in-the-Pulpit**

(From Greek *arts*, a kind of arum, and *haima*, blood, from the spotted leaves in some species)

The only time I ever saw *Arisaema dracontium* in southeastern Florida was in a moist swamp forest in Martin County. These small herbs are related to more tropical plants, but their range in North America is temperate. Our two species (*A. dracontium*, *A. triphyllum*) are known by a variety of names. Americans call them Canada turnip, dragon root, green dragon, Indian turnip, and wild turnip. We also call at least *A. triphyllum* memory root—bite into a raw root, and you never forget the taste!

*Arisaema triphyllum*. a. Habit, b. Outline of one leaflet, c. Spadix, d and e. Berries, f. Seeds. Drawn by Vivian Frazier. From Correll and Correll 1972.

Europeans say *Drachenwurzel grüner* (green dragon-herb, German), *dreiblättriger Aron* (three-leaved Arum, German), *Feuerkolben* (fire herb, German), and *gouet à trois feuilles* (gouge of three leaves, referring to the pointed leaflets, French).

However, the best-known name now is Jack-in-the-pulpit. That name has always seemed strange to me. Who was Jack? Why was he in the pulpit? Why was there not a preacher there?

The name “Jack” is a “pet-name” (or by-name) that dates from at least the 1300s. It was used then much as its synonym “John” is now used for a frequenter of houses of prostitution. This allusion to someone without using his or her real name has been a widespread practice in Western societies throughout time. The allusion also occurs in most other societies, but often for different reasons. Regardless of the reason for usage, one may hear allusionary names such as a Jack (knave), Jack-tar (sailor), Cheap-Jack or Steeple-Jack (laborer), Jack-of-the-clock (the figure of a man who struck the gong on wind-up timepieces), Jack-of-all-trades (a person who can do about anything, with or without the added expression “master-of-none”), male animals (Jack or male donkey), and Jack-o-lantern (the will-o-the-wisp, but also a person who carried around a lantern at night and called out the time). The word is also used in names for plants. Jack-in-the-

pulpit falls in that category, with facetious overtones. First, if “Jack” were a bona fide minister of the gospel, a derogatory term probably would not be used for him. Instead, the “person” in the pulpit (in these plants, the spathe wrapped around the reproductive structures) is a layperson and not a minister.

At first I thought this symbolism and allusion came about because the American plants were not part of the accepted medicinal pharmacopoeia of Europe, but instead used by the “savage” (literally, living in the forest, from Latin *silvaticus*, but historically a condescending term) indigenous people. That is not the case.

Since ca. 1450 the British have used derogatory names for their plants. At first they called their related *Arum maculatum* “cuckoo pindle,” and then shortened that to “cuckoo pint.” Both versions refer to the spadix with words meaning “penis.” Even the British name “Lords and Ladies” emits phallic overtones (Vickery 1995). One has to wonder if missionary George Loskiel knew what he was saying when he called the American species “cuckow pint” in 1794. Jack-in-the-pulpit seems to have been an American extension (applied by 1884) of the old British allusions.

Indigenous names for these plants have been found from only two southeastern groups. *Arisaema dracontium* was *takko* to the Creeks, and *A. triphyllum* was *hichi* to the Choctaw. It is not clear which species the Choctaw called *kifash*, whose root was *hichuk*. However, among the Missouri River people, Gilmore (1919) found for *A. triphyllum* the names *mikasimakan* (coyote medicine, Omaha-Ponca), and *nikso kororik kahtsu nitawau* (*nikso*, corn, *kororik*, resembles, *kahtsu*, medicine, *nitawau*, that resembles, Pawnee). The Plains Cree said *mistusko semina*. An apt name for *A. triphyllum* among the Osage was *e-haw-sho-ga* (bite the mouth; *i-ha'*, mouth, *tha-xta-ge*, bite). They also said *shon-ge i'-t'se-the* (wolf killer; *shon-ge*, wolf, *i'-t'se-the*, with which to kill). The Potawatomi called them *múkwodji'bî* (bear's root), and the Meno-mini say *owässäutci'pa*. The Delaware said *maksáweek [maashk shaweeek]* (*maashk*, defecation, *shawee*, in a hurry, *EEK*, that which causes).

There are records of one or both species being used by at least the Cherokee, Choctaw, Delaware, Iroquois, Malechite, Menomini, Meskwaki, Micmac, Mohegan, Ojibwa, Pawnee, Penobscot, Potawatomi, and Rappahannock. Whether the Creeks of Oklahoma used *A. dracontium* before being relocated there or whether they learned of its use from other relatives is unknown (Howard 1984). Choctaws, for example, boiled *Arisaema* roots in water “to make blood” (Bushnell 1909, Taylor 1940, Vogel 1970). Since the Creek's neighbors in the southeast used it, they likely took the knowledge with them. The Florida Seminoles have apparently lost the knowledge of these plants.

Both species have medicinal uses (Moerman 1998). They have analgesic, antidiarrheal, carminative, diaphoretic, febrifugal, and sedative qualities. They are used as blood and cough medicines, as a cold remedy, to relieve cramps and lameness, as a dermatological aid and expectorant, as eye and throat medicines, for respiratory, skin, and female disorders, as a nose medicine (to induce sneezing), and to treat swelling, tuberculosis, and snakebite.

The seeds were put in gourds to make rattles for children, and the plants also were used in sacred bundles (Menomini) and gave the power of super-natural dreams to the owner (Plowman 1969). The Menomini called *A. dracontium* “owl's foot.” The plant was used in witchcraft (pulverized root used in lip incision to counteract “witchery” to face), and divination (seeds as diagnostic medicine to predict recovery or death). Moreover,

*Arisaema* served as a poison during war (finely chopped roots put in meat for enemies; root cooked with meat in abandoned vessels).

All parts contain acrid compounds, in addition to calcium oxalate, and are strongly irritant and poisonous if eaten raw. Both North American species have been part of the official pharmacopoeia and are listed as either *Radix Aronis dracontii* or *Radix Aronis triphylli* (Hocking 1997). *Arisaema* was recommended by the Eclectics for respiratory disorders, fever, and throat problems (Felter 1922). *Arisaema* was considered especially good for treating chronic laryngitis associated with singing or public speaking. A strong tincture of the fresh root was recommended for application as 1 to 5 drops every half-hour or hour. Additionally, a throat wash of the tincture was taken in a glass of water (Felter 1922). *Caveats* are appropriate.

The roots of both species were highly prized as food by all North Americans (Yanovsky 1936). *Arisaema* was prepared in several ways, but a common method was heating it to expel the poisonous compounds. Some suggest that the roots were sliced thin and roasted “for three days” to get rid of poisons. Millspaugh (1892) had eaten the roasted or boiled roots when young. He declared them good, saying, “I have roasted them myself, when a boy, and enjoyed a repast very pleasing to an empty stomach.” Still, Foster and Duke (1990), Turner and Szczawinski (1991), and Duke et al. (2002) recommend against eating the roots because of the residual and irritant oxalic acid crystals.

Early experiments suggested that the poisons were expressed as a volatile gas that was slightly explosive when mixed with air (Millspaugh 1892). In his summary of folk uses of the Araceae, Plowman (1969) found that those “very labile compounds” had not been identified. The chemicals known from the family include starches, steroidal saponin-like compounds, polyphenolics (including tannins, anthocyanins, and flavones), cyanogenic substances unlike either amygdalin- or linamarin-types, and oxalic acid raphides. *Arisaema* contains the calcium oxalate, mucilage, maybe alkaloids, and probably many of the other chemicals (Plowman 1969, Vogel 1970, Foster and Duke 1990, Foster and Caras 1994). The Old World *A. vulgare* contains a volatile, coniine-like base (Plowman 1969).

American interest always was more in the residual starches until Europeans introduced better sources. Millspaugh (1892) compared the *Arisaema* starches with “arrow root” of the tropics (usually from *Maranta arundinacea*, but also from other species). Those same starches are now used in cosmetics, where they are called “Cupress powder.”

When I was a professor in Florida, a mother and her young son came to me for “advice” about a science project that the boy was doing. He had apparently discovered independently that juice from the live plants applied to wounds stopped the pain. Since he was still in grade school, it seems unlikely that he had scoured the old literature and learned that the natives of North America used the sap in the same manner. Regardless, he was doing an experiment that involved getting as many volunteers as possible to prick their fingers with a needle and then apply juice directly from the plants. I too became one of his subjects with plants that they had imported from New England. We dutifully cleaned the instruments, drew blood from the end of my finger with a needle, and then applied the juice. The pain stopped immediately upon contact with the liquid. They told me that each person they had tested had exactly the same reaction.

Since these plants are no longer common because of habitat loss, I certainly do not recommend having pharmaceutical companies run out and harvest them wholesale to create a new pain-fighting product for the market. However, if you do happen to be near a wild region where the herbs grow, and you wound yourself, keep the young man's experiment in mind. You just might stop the pain before you get back to civilization and apply a more expensive remedy.

### *Aristida*

(From Latin *arista*, the awn or beard of an ear of grain)

*Aristida stricta*. Drawn by  
P.N.Honychurch.

three-awn (a notation of the number of awns on the “seed”)

Linnaeus knew a single species of *Aristida* in 1753. That plant, *A. adscensionis*, had been found in Jamaica and brought to Europe by Hans Sloane before 1696. Now there are about 330 species known in the genus, with one native to Europe (Mabberley 1997).

Gilliland (1975) suggested that the plant was used in thatch by the Calusa. Modern Seminoles on the Big Cypress Reservation still use this genus in weaving baskets. Western species of *Aristida* were utilized in medicines by the Keres, Navajo, and Hopi, but no records have been found of eastern species being used (Moerman 1998).

*Aristolochia*

(From Greek *aristos*, best, and *lochia*, delivery, from its value in aiding childbirth)

***Aristolochia serpentaria*.** From Britton and Brown 1896.

*aristoloche* (French); *aristolochia* (Italian); *aristoloquia* (Portuguese); *Osterluzei* (derived from *Aristolochia*, through *Ostirlucie* in the 13th century, with variations in different locations like *Osterlizen* in Thuringia, *Osterlazei* in Lower Franconia, and *Oschelezei* in the Rhineland. Thus, it has nothing to do with East [*Ost*] or Easter [*Ostern*], and *luzei* has no meaning)

birthwort

*culurain* (Gaelic)

*legeholurt* (*lege*, doctor, *hol*, hollow, *urt*, herb, Norwegian)

***Aristolochia serpentaria*** (referring to the medicinal use to treat snakebite)

*cintó ahissí* (*cintó*, snake, *ahissí*, medicine, Koasati)

[Virginia] Dutchman's pipe (comparison with the flower shape and the similarly curved pipe like the one used by Sherlock Holmes)

*p'lew'óteek* (that which has [grown] from where it started, Delaware)

*pa-us-ka-ton-ga* (like horse hairs; *pa-xin*, hair, *ka'wa*, horse, *e-gon*, like, Osage)

*tiak shua* [*tiaóksês shuwa*] (*tiak*, pine, *shua*, smell, Choctaw)

*tocopate* (*toctli*, green cane, *path*, medicine, Náhuatl, Texas)

*unaste'tstiyú* (very small root, Cherokee)

Virginia [white] snakeroot ("snakeroot" has been used as a name for medicinal plants since at least 1635, but originally applied to either *Polygala senega* or *Aristolochia serpentaria*, or both)

Linnaeus described this species in 1753, and talked about 12 other species. Seven of those species were native to Europe, although 19 are now considered native to the region

around the Mediterranean (Mabberley 1997). Linnaeus gave by far the most space to discussing *Aristolochia serpentaria*. Leonard Plukenet had called the American plants *Aristolochia...seu Serpentaria virginiana* (birthwort...or Virginia snakewort), as had John Ray (1628–1705) in 1704 and Mark Catesby (1682–1749) in 1731. While the European species were known as medicine used during childbirth, it was these new plants from North America that became famous as a treatment for snakebite.

The Natchez of the lower Mississippi Valley took a warm decoction of snakeroot to reduce fevers (Swanton 1928a). The Alabamas mashed the leaves for a snakebite poultice, and drank a tea of leaves to assist the cure (Vogel 1970). The Choctaw took an infusion of roots for stomach pain (Bushnell 1909, Taylor 1940). Their neighbors the Cherokees in the inland Carolinas took an infusion as an abortifacient, as an anodyne against sharp pains in the breast, as a remedy for headache, and to mediate rheumatism. The roots were chewed as a remedy for colds. The plant was also used to treat coughs, fever, sore throat, dyspepsia, ague, pleurisy, and an infusion as an antiseptic. A plant poultice was applied to treat a nose sore from constant blowing, snakebite, and toothache (Hamel and Chiltoskey 1975). The Rappahannock in Virginia put a poultice of crushed roots on spider and snakebites. They also took an infusion of leaves to treat chills (Moerman 1998). People to the north, including the Delaware (eastern New Jersey and Pennsylvania), Micmac (Nova Scotia), Mohegan (Connecticut), and Penobscot (Maine and maritime eastern Canada), also used the plants in medicines (Moerman 1998).

Snakeroot was long used by early settlers for a variety of medicinal applications including snakebite (e.g., Catesby 1731, Porcher 1863). *Aristolochia* is popular in herbal medicine, although it can irritate the gastrointestinal tract and kidneys, potentially causing coma and death due to respiratory failure (Duke 1985, Foster and Duke 1990). Murphee (1965) also found it used to “build up blood.” The vines contain a number of physiologically active compounds including aristolochine and aristolochic acid. Aristolochic acid is carcinogenic and nephrotoxic (Diggs et al. 1999).

### *Arnica*

(Fernald said the origin of the name is disputed; Gledhill says from Greek *arnakis*, lamb’s-skin, from the leaf texture; Ferreira says from Greek *ptarmiké*, a plant whose odor provokes sneezing, through Latin *ptarmica*, to Medieval Latin *arnica*)

*Arnica acaulis*. From Britton and Brown 1898.

arnica (in use by 1753 when Ephriam Chambers wrote the supplement to his *Cyclopedia; or, an universal dictionary of arts and sciences*’, he penned: “*Arnica*...a species of *doronicum*, with plantane leaves”); cognates are *arnica* (French, Italian, Portuguese); *árnica* (Spanish); *Arnika* (German)

leopard’s bane (Europe and Americas) mountain tobacco (Europe)  
*solblom* (sunflower, Norwegian)

***Arnica acaulis*** (stemless)

leopard’s bane (Maryland)

*wi-ti-ya'mubahg'*? (root in the water, Catawba)

Linnaeus created *Arnica* in 1753 without explanation, although most of the authors before him had called the plants *Doronicum*. He reserved that name, another of unexplained etymology, for a different group of Asteraceae. The most famous species in the genus is the European *A. montana*. Although some sources say that the plant has been used medicinally since the 16th century, it is surely older.

Not only is the herb famous as a medicine, but it probably killed Swiss herbalist Konrad von Gesner (1516–1565). Gesner decided to test arnica by taking a dose himself. Soon afterward, he wrote to a friend that there had been no ill effect. However, less than an hour later, he was dead—ostensibly of arnica poisoning (Dobelis 1986).

In spite of the Gesner incident, the plants remain a popular remedy in many parts of Europe. Not only may internal use of extracts be painful, but the sesquiterpene lactones increase blood pressure. The famous poet, philosopher, dramatist, and botanist Johann Wolfgang von Goethe (1749–1832) took arnica in his old age to relieve his angina (Bown 1995, Swerdlow 2000). Duke et al. (2002) say *A. montana* should not be used internally, although there is good evidence that external applications are effective. The species is still used internally in Germany, but is restricted to external use in the United Kingdom and the United States (Bown 1995).

When Europeans familiar with arnica arrived in the New World, they found indigenous people using other species. *Arnica fulgens* (Saskatchewan to North Dakota, west to British Columbia and California) was used on wounds and sore muscles by local tribes (Dobelis 1986). Vogel (1970) also lists *A. acaulis* (as *A. nudicaulis*), *A. cordifolia* (Arkansas to Arizona, east to South Dakota), *A. sororia* (Wyoming to British Columbia, Utah, and California), and *A. mollis* (Gaspé Peninsula and Quebec to Maine and New York west to Colorado and California) with medical properties that were used by native people. Moerman (1998) found records confirming that *A. cordifolia* and *A. latifolia* were used by the Okanagan-Coville, Shuswap, and Thompson tribes.

The only species in the southeastern United States is *A. acaulis*. This species ranges from Pennsylvania and Delaware south through the Carolinas, Georgia, and northern Florida. The only record found of local use was by the Catawba, who made *A. acaulis* into medicine that they drank for back pain (Vogel 1970, Hocking 1997). Hetz and Sosa (1988) have established that this species contains sesquiterpene lactones like many others in *Arnica*, and Merfort (1994) confirmed that it also contains flavonoid glycosides.

Although various species of arnica have been used for a variety of ailments, the only use now sanctioned by most is external (Bown 1995, Duke et al. 2002). Externally, the

plant is considered bactericidal and vesicant, and is used to treat bruises, sprains, abrasions, and slight wounds. During World War II, the American species were so widely used that they became considered equal in healing power to the European *A. montana* (Vogel 1970). Mabberley (1997) considered *A. fulgens* more effective than *A. montana*.

### *Arnoglossum*

(From Greek *arnos*, lamb, and *glossa*, tongue, referring to the leaves, and reapplied by Rafinesque to these plants; *Arnoglossa* is the ancient Greek name for plantain, *Plantago* major, and *P. lagopus*)

*Arnoglossum atriplicifolia*. From Britton and Brown 1898.

*Arnoglossum atriplicifolia* (having leaves like *Atriplex*) (= *Cacalia atriplicifolia*)

*da'yewû* (it sews itself up, because the leaves were thought to grow together again when torn, Cherokee)

pale Indian plantain (perhaps because the indigenous people used it as Europeans did *Plantago*)

tassle flower

*Arnoglossum* is another of the myriad new names created by Rafinesque. Many of the names he proposed are untraceable, but this one is. He proposed *Arnoglossum* in his *Florula Ludoviciana* (Louisiana Flora) of 1817. However, it was Linnaeus who described the species in 1753 as *Cacalia atriplicifolia*. Indeed, it was not until Harold Robinson studied the two genera in 1974 that they were separated. As now understood, *Arnoglossum* consists of seven species in the eastern United States (Mabberley 1997).

Core (1967) indicated that the leaves were eaten as a pot-herb. The Cherokee sprinkled the powdered leaf over food like salt (Mooney 1885–1886) and also used *da'yewû* as a poultice to remove blood or poisonous matter from cuts, bruises, and “cancers.” The bruised leaf was bound over the spot and frequently removed and replaced (Hamel and Chiltoskey 1975).

*Artemisia*

(Named for *Artemisia*, the Greek Diana, goddess of chastity, as the plant was thought to bring on early puberty; Pliny, A.D. 23–79, used the name for the mugwort, *A. vulgaris*; he said that the name was in honor of Artemisia, wife of Mausolus, king of Caria)

*amarella* (little bitter one, Italian)

*armoise* (from *artemisia*, French); *artemisia* (Spanish); *artemisia verdadeira* (real artemisia, Portuguese)

*Beifuss* (close to your foot, German)

*bollan bane* (worn on 5 July, midsummer day on the Old Calendar, to repel witches on the Isle of Man); *bollan feailleoin* (synonym for *bollan bane*)

*burmaid* [*burmaill*] (for *A. absinthium*, Gaelic)

*burot* (cage root, Norwegian)

*hierba de San Juan* (Saint John's herb, Spanish)

*laanah* (for *A. herba-alba*, Hebrew)

*liathlus* (*liath*, sweet milk or feast, *lus*, herb, Gaelic, for *A. vulgaris*)

*malurt* (cognate with English mugwort, for *A. absinthium*, Norwegian); motherwort (a name applied to plants used to treat diseases of the womb, formerly *A. vulgaris*, now *Leonurus*); *muggart* (Scottish); mugwort (first recorded ca. A.D. 1000, of Teutonic origin from West Germanic *muggiwurti*)

*muse'odji'bik* (worm root, for *A. absinthium*, Ojibwa)

*pe'-zhe-xu-a* (*pe'-zhe*, herb, *xu-a*, sacred, Osage)

sage-brush [sagebrush, -bush] (apparently first used by Elliott Coues in 1872 in his discussion of North American birds; the allusion is to the odor of the plants resembling *Salvia*)

wormwood (originally confined to *A. absinthium*; first used ca. A.D. 1400; there are two versions of the origin of the name: one says it is a reference to its use in expelling intestinal worms, and also “worms” such as moth larvae and fleas that infested clothes and bedding; the other version is that it is based on Teutonic *wer*, man, and *mod*, courage; that version alludes to aphrodisiac and healing traits); *Wurmut* (“preserver of the mind,” for *A. absinthium*, German)

*Artemisia campestris* (of fields or plains)

*armoise rouge* (red wormwood, Quebec)

*aruone sauvage* (wild wormwood, Quebec)

*Déné k'áze 'eya ha nadié* (person's throat hurts for this medicine, Chipewyan, Canada); *kotzezi naydi* (Slave, Canada)

[thread-leaf, western] sagewort

[Canadian, plains, sea] wormwood

Linnaeus ([1753] 1957) knew 19 species of *Artemisia*. According to Mabberley (1997), 55 of the ~350 *Artemisia* species are native to Europe. Given its history as medicine and

culinary flavoring, no doubt explorers in the New World were pleased to see these familiar aromatic herbs (de Cleene and Lejeune 2002).

Like several of the other *Artemisia* species, this one has been broken up into a number of subspecies (Kartesz 1994). Moerman (1998) lists four subspecies of *A. campestris* that have been used by North American tribes.

The Blackfoot used the herbs to help tan hides, and the Lakota used them as body perfume. The Navajo used the seeds in a food.

In the eastern United States, the Menomini used this herb in a medicine to control menstruation. They also used it with *Angelica* for a poultice to relieve pain (Hocking 1997). The Meskwaki made a medicine of it for burns. Farther west on the plains, the Lakota made medicines that were diuretic, laxative, and sedative. The Blackfoot used it for abortions in difficult pregnancies, applied it to rheumatic parts, to remove scalp infections, for eczema and sore eyes, and for stomach trouble and coughs. Other people using the plants included the Chipewyan, Havasupai, Navajo, Okanagon, Shuswap, Slave, Tewa, and Thompson.

The genus is noted for chemicals that are toxic and under legal restrictions in some countries (Bown 1995, Swerdlow 2000). Among those compounds are thujone, cineole, and santoxin.

### *Arundinaria*

(A genus created by French botanist André Michaux from Latin *arundo*, a reed, plus the suffix *-inis*)

*Arundinaria gigantea* (very large or giant)

*ʔa'la* (Tunica); *afho 'ti* (cane-brake, Ofo)

*axoki'* (Biloxi; related terms are *kiduni*, canebrake; *axo'k dutca 'ti*, split cane; *axo'k dutca 'ti natcon'*)

*Arundinaria gigantea*. Drawn by Leta Hughey. From Hitchcock and Chase 1950.

*nkoŋ nkoŋ nda'sk nkoŋ*—I make baskets and mats out of split cane)  
bamboo cane (“bamboo” perhaps from Malay, Sudanese, and Javanese *bambu*; maybe from Canarese *banbu* or *banwu*; first appearing in English by 1586)

cane [giant, large, river, southern, switch] (“cane” is from Middle English *canne*, appearing in English by 1398); *canne* (Houma, French)

*itani* (Alabama); *itani* (Koasati); *íáwv* [ráwv] (Muskogee); *oŋā:ní* [orā:ní] (Mikasuki)

*koça* [konshak] (Choctaw); *kóhv* [kohà, kóha, koha] (Creek)

*nissakan* (Strachey [1612] 1953 wrote the Powhatan name *nissakan*, *nisake*, and *nehsaakan*, translating it both as “reed” and “cane”; Siebert 1975 found the root *\*ni-ʔT-* in Menomini as *ne-ʔn-*, Ojibwa as *ní:ss-*, and *nehse-* in Penobscot)

*oski* [oske, houski] (Mobilian, cf. Drechsel 1997, from Choctaw *oski* [uske, uski]); *oski'* (Chickasaw)

*pahiló:cí* (*pahi*, grass, *ló:cí*, black, Mikasuki; the name of a dance fide Sturtevant 1955)

*Rohr* [gras] (German)

*tu* (Atakapa)

*wása'* (Catawba)

Although I have no idea how old I was, I still remember my first encounter with a cane-brake. My grandparents lived just above the floodplain of the Tennessee River in a remote part of west-central Kentucky. Beside their home was a small creek that we had to cross to visit them, walking when the water level was low, in a boat when the water level was high. Just above floodline on one bank, we always passed a large stand of canes. When I was a fairly young child, I ventured to explore that thicket alone and found a mysterious green wonderland. Some of the cane stems were 5 cm (2 inches) in diameter and reached 4.5 to 6 m (15 to 20 feet) tall. At the time, I had no idea of their famous reputation as sleeping places for black bears (*Ursus americanus*) or they would have been even more exciting. Looking back, I have to wonder if part of the mystery was the same feeling that indigenous people in the southeast had about this arguably most useful of American grasses.

Creeks used an expression *kóha-v'lvk* (cane-brake, Muskogee) to describe these thickets. Choctaw said they were *uski pata* (*uski*, cane, *pata*, broad or spread). In Cleburne County, Alabama, there is a stream called Cahulga Creek, meaning "canebrake creek," from Muskogee *kohv*, cane, *vlke*, grove. Perhaps that was the original source of the name "cane-brake" being used in English by 1769. The Choctaw called what is now the State of Kentucky *uski anunka* (among the canes).

Bartram ([1791] 1958) described observing what he thought might be "the most extensive Cane-brake that is to be seen on the face of the whole earth" near the Creek village of Talahaschote (*talwa*, town, *ahassee*, old, *chee*, little) on the Suwanee River in Levy County, Florida. As explanation, he added that in the Carolinas they are called "cane meadows."

Extensive "cane-brakes" of *Arundinaria* grew in the southeastern states until about the early 1950s, particularly along larger waterways. Virtually all of those "brakes" were destroyed by grazing cattle, for agriculture, and housing to the point that the species is rare throughout its former range (Platt and Brantley 1997).

The word cane applies to several different plants, but two, sometimes three, native Florida grasses have that designation. One is *Arundinaria*, used for fishing poles and for constructing the most expensive fly-fishing rods; the other, *Lasiacis*, currently is not used by people in Florida. Sometimes people also call the giant reed (see *Phragmites*) a cane. People elsewhere in the Americas use all three genera and distinguish between them with common names, while at the same time noting their similarity.

Moreover, the words *reed* (see *Phragmites*), *cane*, and *bamboo* are intermixed in current and historical usage. All originally had somewhat different meanings and origins; yet, all came into English because of grasses.

"Cane" came to modern English from Middle English *canne*, through Old Frisian *cane*. These are based on Latin *canna*, and Greek *kanna*, reed. According to Zohary (1982) the Greek and Latin words were originally taken from the Semitic words in Hebrew *kaneh* or *qáneh*, and Arabic *qanáh*. In Latin the sense was extended from "(hollow) reed or cane" to "tube or pipe." The word "cane" appeared in English in 1398 in the sentence: "A noyse as it were wyth a canne other a great reyd."

"Bamboo" is the word most recently incorporated into English, although the origin is unclear. Some think it came from Malay, Sudanese, and Javanese *bambu*, but others think the word was introduced there from elsewhere. The people who think that it is a loanword in those languages suggest that the original word was Canarese *banbu* or *banwu*.

Regardless, the word was used first in Portuguese by Garcia de Orta, who had worked as a physician in Asia. In his 1563 book *Simples e Drogues*, he wrote “*Aquellas canas daquela arvore chamam os Indios, onde nasce, mambu*” (The canes of that tree the Indians where it grows call *mambu*). From that point, “bamboo” became incorporated into English within about two decades.

Obviously, the concepts of “reed,” “cane,” “bamboo,” and “pipe” are all interrelated and applied to numerous plants. The first requirement is that the grasses are comparatively large, and have either a woody stem or one that is somewhat lignified. The most useful part of the grasses is the stem, and that structure has served people throughout the world in multiple ways.

Probably the first account of American canes occurs in the records of the de Soto expedition. On 13 October 1540, the group entered the province of *Mabilia* (maybe “to paddle,” Choctaw) in what is now Clarke County, Alabama. Although the modern city of Mobile took its name from that region, it occupies a different location. There were hostile encounters and the Spaniards were forced to cross the Alabama River on cane rafts near the modern city of Claiborne (Swanton 1946). The chronicler known as the Gentleman of Elvas wrote that the Spaniards made the crossing on “rafts of canes and dry wood” (Swanton 1939).

Another early record was left by Henri de Tonti in his account of meeting the Taencas in 1692 in what is now northeastern Louisiana. He and La Salle had just left the *Arkancas* [*Arkansae*] (Arkansas, their name came from what the Illinois called them) near the mouth of where the river that bears their name met the Mississippi, and traveled south. The *Arkancas* lived in “cabins made with the bark of cedar.” However, after entering the village of the Taencas, he wrote: “I was surprised to find their cabins made of mud and covered with cane mats” (Tonti in Borland 1965). Tonti and La Salle had finally entered the cultures of the southeast where the canes were dominant.

The first scientific record of giant cane in Europe was when Thomas Walter published his *Flora of the Carolinas* in 1788. He called the species *Arundo gigantea*, thinking they were related to that famous Mediterranean grass *A. donax*. André Michaux realized that the American plants were distinctive, and created the genus *Arundinaria* in 1813. Other people also found these giants interesting, and there are no fewer than 21 other synonymous names that have been given to them. The southeastern species has even been put in the Old World genus *Bambusa*.

American bamboos grow in the river systems connected to the Mississippi and Coastal Plain. The species is known in southern Missouri, Illinois, Indiana, Ohio, south into Florida, eastern Texas, and southeastern Oklahoma (Hitchcock and Chase 1950). There have been ~50 other species put in *Arundinaria*, but some have been moved to other genera recently. Other species grow in South America and in Asia (McClure 1973, 1993, Mabberley 1997).

To most, if not all, southeastern people, *Arundinaria* canes were items used on a daily basis. Canes were used for arrow shafts, blowguns, blowgun darts, blowing tubes for medicines (*istoopofilka*; *ist-oo*, blowing, *pofilka*, pipe, Alabama), bows (*eccv kotakse*; *eccv*, gun, *kotakse*, crooked, Creek), building material for wattle and daub, fiber for weaving moccasins (Whitford 1941), flutes (*fehvp*, Creek), fuel, knives, lighting (candles), mats (*pachalh*, Choctaw; *kohv topv*, scaffold cane, and *kohv tvrke*, woven cane,

Creek), medicine, and war spears (Sylestine et al. 1993, Munro and Willmond 1994, Moerman 1998, Martin and Mauldin 2000).

William Bartram ([1791] 1958) provided some of the most detailed information about these grasses in Alabama, Florida, Georgia, Louisiana, and North Carolina. He too recounts making a raft from the stems. At Otassee, Alabama, near where the de Soto army made their rafts, he wanted to cross a branch of the Alabama River that was flooded from rains. He and his companions decided they had to ferry their goods across, and he wrote: "I undertook to collect dry Canes, and my companions dry timber and logs and [grape] vines to bind them together: having gathered the necessary materials, and laid them in order [we]...set about building our raft." They put the tree trunks together to form the base, and then gathered the canes, "in bundles, each near as thick as a man's body," to make the upper layer.

The Creeks made a unique arrangement of canes into a spiral fire to illuminate meetings in buildings. Bartram ([1791] 1958) described the fire when he was in the town of Attassee [Otassee] (properly *Atasi*, an Upper Creek town on the south side of Tallapoosa River, just below the mouth of Calebee Creek, Macon County, Alabama, Harper 1958). He wrote: "As their vigils and manner of conducting their vespers and mystical fire in the rotunda, [*sic*] is extremely singular, and altogether different from the customs and usages of any other people, I shall proceed to describe it. In the first place, the governor or officer who has the management of this business, with his servants attending, orders the black drink to be brewed, which is a decoction or infusion of the leaves and tender shoots of the Cassine: this is done under an open shed or pavillion, at twenty or thirty yards distance, directly opposite the door of the council-house. Next he orders bundles of dry Canes to be brought in; these are previously split and broke in pieces to about the length of two feet, and then placed obliquely crossways upon one another on the floor, forming a spiral circle round about the great centre pillar, rising to a foot or eighteen inches in height from the ground; and this circle spreading as it proceeds round and round, often repeated from right to left, every revolution encreases its diameter, and at length extends to a distance of ten or twelve feet from the centre, more or less, according to the length of time the assembly or meeting is to continue. By the time these preparations are accomplished it is night, and the assembly have taken their seats in order. The exterior extremity or outer end of the spiral circle takes fire and immediately rises into a bright flame...which gradually and slowly creeps round the centre pillar, with the course of the sun, feeding on the dry Canes, and affords a cheerful, gentle and sufficient light until the circle is consumed, when the council breaks up."

Bartram ([1791] 1958) was among the first to describe canes being used to make hairpins, and of the Creeks spearing "salmon trout" (*Micropterus salmoides*, now called largemouth bass) with a cane "harpoon."

When talking of Creek dress, Bartram ([1791] 1958) wrote: "The men shave their head, leaving only a narrow crest or comb, beginning at the crown of the head, where it is about two inches broad and about the same height, and stands frizzed upright; but this crest tending backwards, gradually widens, covering the hinder part of the head and back of the neck; this lank hair behind is ornamented with...[silver quills and silver plates], and usually the middle fascicle of hair, which being by far the longest, is wrapped in a large quill of silver or the joint of a small reed, curiously sculptured and painted, the hair continuing through it terminates in a tail or tassel."

Neither Romans ([1775] 1961) nor Bartram ([1791] 1958) was complimentary about southeastern music. Romans wrote that Chickasaw men send their women to work in the fields and then “they play on a aukward kind of flute made of a cane.” Bartram described Creek music as “both vocal and instrumental; but of the latter they have scarcely any thing worth the name, the tambour, rattle-gourd, and a kind of flute, made of the joint of a reed.” He thought that with the flute they “performed badly, and at best it is rather a hideous melancholy discord.”

Of catching fish with cane spears, Bartram ([1791] 1958) wrote: “One of our Indian young men, this evening, caught a very large salmon trout, weighing about fifteen pounds, which he presented to the Col. [Barnet; but Harper (1958) thought that was a misprint for Col. James Barlett] who ordered it to be served up for supper. The Indian struck this fish, with a reed harpoon, pointed very sharp, barbed, and hardened by the fire. The fish lay close under the steep bank, which the Indian discovered and struck with his reed; instantly the fish darted off with it, whilst the Indian pursued, without extracting the harpoon, and with repeated thrusts drowned it, and then dragged it ashore.”

Among some villages in the Creek confederacy, cane also played a role in marriages. Bartram ([1791] 1958) described a marriage: “When a young man has fixed his affections, and is determined to marry, he takes a Cane or Reed, such as they stick down at the hills of their Bean vines for their support: with this... he repairs to the habitation of his beloved, attended by his friends and associates, and in the presence of the wedding guests, he sticks his Reed down, upright in the ground, when soon after his sweet-heart comes forth with another Reed, which she sticks down by the side of his, when they are married; then they exchange Reeds, which are laid by as evidences or certificates of the marriage.”

However, the most famous use of canes by the Catabwa, Cherokees, Chitimacha, Choctaws, Creeks, Houma, Seminoles, and Yuchi, and perhaps others in its range in the southeastern United States was as blowguns. The “gun” or tube was called *oski* (cane, Chickasaw), *kohv motke* (*kohv*, cane, *motke*, cut off short, Creek), *wókko* (Muskogee) by the Taskigi Creeks, *kaklu'mpa* or *uski lumpa* by the Choctaw (Bushnell 1909). To the Alabama, they were *ifanibihí* (*ifani*, cane, *bihi*, bow). These tubes were often 2 m (7 feet) long, but sometimes among the Cherokee reached 3 m (10 feet). Choctaw darts were made of cane (*uske*) or pine. Creek darts were *takfylvlvke*; to the Choctaw, they were *shumatti* [*shuma'nte*] (from *shumo*, thistle down, *holutti*=?). The darts were “feathered” with thistle down (*Cirsium*) or fireweed down (*Epilobium* or *Erechtites*). Depending on the length of the tube and the skill of the user, they were accurate from 7.6 to 18 m (25 to 60 feet) (Swanton 1946), although Romans ([1775] 1961) says up to 20 yards. The southeastern region was the only one in North America that used this largely South American hunting instrument. While most tribes long ago ceased using the blowgun, demonstrations of former use can be seen in the replica of an old village in Cherokee, North Carolina.

In 1761, Lieutenant Henry Timberlake observed that Cherokee children, “at eight or ten years old, are very expert at killing with a *sarcaban*, or hollow cane, through which they blow a small dart...and they seldom miss” (Swanton 1946).

Jean Bernard Bossu, writing in 1768, noted that the blowguns used by the Choctaw were about 7 feet long, and that, “when they see something [which they want to hit] they blow into it, and they often kill small birds” (Swanton 1946). Bernard Romans ([1775]

1961) visited the Choctaw not long afterward and recorded that they “use a very strait cane, eight or nine feet long, cleared of its inward divisions of the joints; in this they put a small arrow, whose one end is covered one third of the whole length with cotton or something similar to it; this they hold nearest their mouth and blow it so expertly as seldom to miss a mark fifteen or twenty yards off and that so violently as to kill squirrels and birds therewith.”

Although few people now realize it, American cane was formerly an important food for people within its range. Until recently, two species were recognized. *Arundinaria gigantea* is the larger of the forms, reaching 8 m (25 feet) tall and fruiting erratically, perhaps every 40 to 50 years. Smaller plants, growing to 1 to 4 m tall (3 to 12 feet), were called *A. tecta* (switch-cane, reed, small-cane), and fruited every 3 to 4 years (Fernald et al. 1958). Even the Choctaw recognized the large cane as *oskonush* (*oski*, cane, *onush*, wheat, probably originally for *Arundinaria* and later shifted to *Triticum*), and the small one as *oskish* or *oski shifilli*. Now, the smaller plants are considered a subspecies of *A. gigantea* (McClure 1973).

The smaller subspecies *tecta* flowers and fruits regularly and people throughout the southern states harvested the seeds and used them as we do wheat (*Triticum*) flour (Hedrick 1919). In 1828, Timothy Flint recorded in his book *A Condensed Geography and History of the Western States, or the Mississippi Valley* that *Arundinaria* “produces an abundant crop of seeds with heads very much like those of broom corn. The seeds are farinaceous and are said to be not much inferior to wheat, for which the Indians and occasionally the first settlers substituted it.”

The parent plant dies after fruiting, and the remaining seeds sprout to produce new plants. The young shoots on those were similarly gathered and eaten as potherbs, much as we now use oriental bamboo shoots (Fernald et al. 1958). Although the larger subspecies *gigantea* fruited irregularly, it provided many acres of gigantic fruiting stems when the event did occur. At those times, the grasses were not only important food sources for humans, but also for many seed-eating birds and other animals.

At least the Choctaw, Houma, and Seminoles used *Arundinaria* as medicine. The Choctaw made a root decoction to relieve chest pains (Taylor 1940). The Houma made a decoction by boiling the root. The resultant liquid was “drunk by persons past forty-five or fifty to renew strength, and specifically to stimulate the kidneys” (Speck 1941). The liquid was to be “drunk as hot tea every day for nine days.” The Seminoles treated *layksinkoslihci* (constipation, or “feces stopped-up” sickness, Mikasuki) by boiling the root of *otani* and drinking the mixture (Sturtevant 1955). As with several other grasses, the seeds are sometimes consumed by a toxic fungus and become dangerous (Foster and Duke 1990).

Bartram ([1791] 1958) described visiting a Seminole village near a white settlement called Charlotia, on the St. Johns River between what is now East Palatka and San Mateo in Putnam County. There he was greeted in 1774 by the people and ushered into a “grand, airy pavillion in the center of the village. It was four square; a range of pillars or posts on each side supporting a canopy composed of Palmetto leaves, woven or thatched together, which shaded a level platform in the center...all covered with carpets or matts, curiously woven of split canes dyed of various colours; here being seated or reclining ourselves, after smoaking tobacco, baskets of choisest fruits were brought and set before us.”

Cane splints from the stems historically were used to make mats and baskets by tribes in the Creek Confederacy, including the Cherokees. The Alabama called these baskets *itanikolbi* (*itani*, cane, *kolbi*, basket). The Alabama boiled *ittokchakkosi* (wild cherry tree) bark to make a red dye that was used to color cane in the baskets (Sylestine et al. 1993).

This art is not lost; it can still be found on the Cherokee reservation in North Carolina. However, the grasses are now so rare, and the skill so demanding, that the items command prices of at least three figures.

### *Asarum*

(Linnaeus continued using the Greek name for the plants, *asaron*, used by Dioscorides, fl. A.D. 40–80)

***Asarum arifolium*.** From Britton and Brown 1896.

*asair* (Gaelic); *asaret* (French); *asaro* (Italian)

*aschquoerista* (probably *A. canadense*, Onondaga)

azarabacca [asarabacca] (apparently from *asarum*, the plant, and *bacca*, fruit, Turner [1548] 1965)

*e-haw-nes-ni* (water comes in the mouth; *i-ha'*, mouth, *ni*, water, for *A. canadense*, Osage)

fole-foot (used by Turner [1548] 1965; alludes to the shape of the leaf resembling a young horse's [foal] hoof, cf. Britten and Holland [1886] 1965)

*gingembre sauvage* (wild ginger, for *A. canadense*, Quebec)

*Haselwurz* (hazel wort, German)

*name'pin* (sturgeon plant, for *A. canadense*, Ojibwa)

*Asarum arifolia* (with leaves like *Arum*)

*ha mot' pa'tki ye* (*mot' pa'tki ye*, flat, *ha'*, leaf, Catawba)

heartleaf (so called by A.W.Chapman because of the cordate leaf shape, Florida in the 1800s)

little brown-jug (an allusion to the shape of the flowers)

wild ginger (“ginger” from Old English *gingiber*, from the Latin *zingiberi*, akin to Sanskrit *crngavera*, perhaps compound from *crnga*, horn, *vera*, body, from the similarity of the rhizome to a stag’s horn)

*Asarum virginianum* (of Virginia)  
Virginia heartleaf

Linnaeus ([1753] 1957) knew four species of *Asarum*, with two of them native to Spain, Portugal, and other parts of Europe. The most famous of the Old World species, *A. europaeum* (asarabacca or hazelwort), was well known as a medicine. Not only was it used to treat alcoholic excess (emetic), but it is considered antiasthmatic and an immune stimulant (Bremness 1994, Mabberley 1997). After the 1520s, it became fashionable to use snuff, and hazelwort was sometimes used alone or added to tobacco.

The most widespread species in the eastern United States is *A. canadense*, and that is the one with the most documented uses (Densmore 1928, Yanovsky 1936, Moerman 1998). That species has been used throughout its range for medicine, food, snuff, and perfume (Moerman 1998). Canadian people used the root for many complaints, including heart problems (Vogel 1970). The Menomini, Meskwaki, Ojibwa, and the Potawatomi thought the root made food palatable to sick people, regardless of the malady they suffered (Vogel 1970, Moerman 1998). Several groups considered the root good for treating throat trouble, earache, lung troubles, and stomach cramps. Virtually throughout its range, people used the roots to season food. Although they do not list them, Fernald et al. (1958) note that other species may be used like *A. canadense*. Bown (1995) also listed a number of species that have been similarly used for seasoning and medicine. These and other data suggest that other species were substituted for *A. canadense* outside its range. For example, the Catawba are known to have used *A. arifolia* for heart problems (Speck 1932, Vogel 1970).

### *Asclepias*

(Named for legendary Greek physician and deity Asklepios or Aesculapius)

*Asclepias tuberosa* (with tubers)

archangel (Rhode Island)

*asclepiade tubereuse* (tuberous milkweed, French)

butterfly’s bed (Oklahoma); butterfly-[flower, milkweed, root, weed] (“butterfly-weed,” in use by 1830); *tyffo* [em] *ohlikitv* [ohliketv] (*tyffo*, butterfly, [em, its], *ohlikitv*, chair, Muskogee); *yepanane* <sup>?</sup> *wi-ti(re)* (butterfly medicine, Catawba)

Canada-root

chigger-flower [chiggerweed] (“chigger” was in English by 1769, having been derived from an African word akin to Wolof *jiga*, insect, Missouri)

colic root [colicroot] (a name more often given to *Aletris*)

*env'ce-enok'ke-heléswv* (*env'ce-enok'ke*, pleurisy, *heléswv*, medicine, Muskogee)

flux root [fluxroot]; [pleurisy, rubber, tuber, white]-root; wind [weed, root] [windweed, windroot]

fly catcher [flycatcher] (because of the “trap” that catches the legs of flower visitors)

grasshopper's bed (Oklahoma)

*hatapushik okhinsh* (*hatapushik*, butterfly, *ikhinsh*, medicine, Choctaw)

Indian-[bokay, paint, plume, posy, nosy] (Michigan, Texas)

*ishkobo' homma* (*ishkobo'*, head, *homma*, red, Chickasaw)

*kiu makan* (wound medicine, Omaha-Ponca); *makan saka* (*saka*, raw [as fresh wounds], *makan*, medicine, Omaha-Ponca); *makan saka thata i* (medicine they eat raw, Omaha-Ponca)

*knollige Schwalbenwurz* (tuberous swallow herb; the modifier distinguishes it from dogbane, which see, German)

*kuku'* (*Cherokee*; the word gave rise to the modern localities of Coco Creek, of Hiwassee River, and Coker post office, in Monroe County, Tennessee)

orange [apocynum, milkweed, swallow-wort, swallowwort, root]

silk-grass (the name was in use by 1620 for a variety of plants; it was first applied to a kind of “flag,” then later to other fiber-producing species; in use by 1750 for *Asclepias*)

silkweed (in use by 1837: “This beautiful plant has already, by the French nation, been cultivated to advantage. The pappus is spun with raw silk for gloves, the juice collected for opium, and the leaf useful in dying,” Williams [1837] 1962; as *A. phytolacchoides*)

swallow-wort [swallowwort]

yellow milkweed (Massachusetts)

*zaip-ya-daw* (*daw*, tree, Kiowa)

Europeans were well acquainted with *Asclepias* when they arrived in the New World. However, they were not prepared for the orange flowers of this herb and quickly took them back to the Old World. By 1687, the plants were already in cultivation in the Netherlands, although they were surely imported through England or Spain. The first records of *A. tuberosa* being grown in London are from Dillenius's *Hortus Elthamensis* of 1732, although it probably arrived there even earlier. By 1738, Linnaeus had studied the plants at the *Hortus Cliffortianus*.

Because of its showy flowers and habit of growing on moist roadsides, *A. tuberosa* is the best-known species in the eastern United States. These were plants of multiple uses, including dyes, food, fiber, and medicine. The Meskwaki used *A. tuberosa* as a dye. Millspaugh (1892) recorded: “The Western Indians boiled the tubers for food; prepare a crude sugar from the flowers, and eat the young seed-pods after boiling them with buffalo meat. Some of the Canadian tribes use the young shoots as a pot-herb after the manner of asparagus.” The Dakota and Delaware cooked and ate them as they did *A. incarnata* (Yanovsky 1936). Still, Fernald et al. (1958) were not enthusiastic about the species as food. The Cherokee wove the stem fibers into belts (Hamel and Chiltoskey 1975).

Its reputation as a medicine was slower to develop. One of the first records of medical use is from 1750 (Vogel 1970), when Jane Colden wrote in a manuscript that remained unpublished until 1963 that "Silkgrass" root was "an excellent cure for the colick, about half a spoonfull at a time. This cure was learn'd from a Canada Indian, & is called in New England Canada Root." John Bartram wrote in 1751 that for pleurisy "the root must be powdered and given in a spoonful of rum, or rather as the Indians give it, bruise the root and boil it in water and drink the decoction. Peter Kalm saith it is excellent for hysteric passion."

Colden, Bartram, Kalm, and others learned uses from indigenous people. We now have records that pleurisy root was used by the Catawba, Cherokee, Delaware, Iroquois, Menomini, Meskwaki, Mohegan, Natchez, Navajo, Omaha, Ponca, Potawatomi, Rappahannock, and Seminoles (Smith 1933, Vogel 1970, Howard 1984, Moerman 1998). Undoubtedly, more tribes applied it.

The Catawba made a decoction of the roots to stop dysentery (Vogel 1970). The Cherokee used it as an analgesic, to stop diarrhea and bloody flux, as an expectorant, in treating heart trouble, and as a laxative (Hamel and Chiltoskey 1975). The Delaware treated pleurisy and rheumatism, and used it to aid childbirth (Moerman 1998). The Iroquois used it, probably among other purposes, for added strength in sports. Huron Smith called it "one of the most important Menomini medicines" (Vogel 1970). This tribe used it for bruises, cuts, lameness, swellings, and wounds; they also took it as a tonic. They pulverized the root and used it for cuts, wounds, and bruises, as well as mixing it with other roots for other remedies. The Natchez thought it the best remedy for pneumonia and "winter fever." They boiled the roots and took a cupful at a time (Vogel 1970). The Mohegans treated pleurisy with the dried root. The Omaha and Ponca ate the raw root to treat bronchial and pulmonary troubles (Gilmore 1919). They also chewed the root and put it on wounds and sores that were slow to heal. The plants also played an important part in the Omaha Shell Society and its rituals. The Potawatomi used *A. tuberosa* as a poison antidote (Smith 1933, Vogel 1970). The Rappahannock put the bruised leaves on snakebite (Moerman 1998). Howard (1984) was told by the Oklahoma Seminole Willie Lena that he boiled the plant and told his patients to drink the infusion; baths of it also serve as a general tonic. The Seminoles used it in 1919 to treat snakebite (von Reis and Lipp 1982).

Millspaugh (1892) found that early reports of using *A. tuberosa* as medicine were left by J.D.Schopf in 1787, Benjamin Barton in 1810, John Eberle in 1825, A. Nathaniel Chapman in 1827, and Benjamin Parker in 1841. By the time of the Civil War, Porcher (1863) gave a thorough discussion of the species. He wrote: "This plant is actively diaphoretic and expectorant, without being stimulant.... In large doses, it is purgative. It has been advantageously used in rheumatism, in most pectoral affections, catarrh, subacute pneumonia, and in phthisis, as a palliative. It has also been favorably employed in dysentery.... The powdered root has been employed as an escharotic, for restraining the growth of fungous flesh in ulcers. When the diaphoretic effect is desired the decoction of one ounce of the root to one quart of water is best, given in doses of a teacupful every two hours. Dose of powdered root, twenty grains to one drachm several times a day.

"In the neighborhood of Camden, South Carolina, the root of silk-weed (pleurisy root) is much relied on in rheumatism. The root is macerated in brandy. It is believed by many

that it has a marked influence in promoting the excretion of bile, and the tincture is said by those who use it to have a laxative effect. It is used as a substitute for calomel....

“The milky juice exuding from *Asclepias*, *Leontodon*, *Lactuca*, and the Euphorbiaceae yield caoutchouc. I would suppose that the queen’s delight (*Stillingia*), which is abundant, would also furnish it. It might be procured from those which give a large exudation of milk when cut. I have collected and dried the juice of *Asclepias*.

“The downy substance attached to the seed of the silkweeds may be used for many purposes—for stuffing beds, cushions, etc.” (See *Asclepias*: Milkweed below for fiber uses.)

Millspaugh (1892) wrote that, up to his time, “The pleurisy-root...has been regarded...as subtonic, diaphoretic, alterative, expectorant, diuretic, laxative, escharotic, carminative, anti-spasmodic, anti-pleuritic, stomachic, astringent, anti-rheumatic, anti-syphilitic. ... It has been recommended in low typhoid states, pneumonia, catarrh, bronchitis, pleurisy, dyspepsia, indigestion, dysentery, helminthiasis, and obstinate eczemas.”

*Asclepias tuberosa* was official in the U.S. Pharmacopoeia from 1820 to 1905 and in the National Formulary from 1916 to 1936. Roots of this and other members of the family are considered diaphoretic and expectorant, and in large doses emetic and purgative (Vogel 1970).

As with several other species, *A. tuberosa* contains asclepain, which has been used to remove warts (Bremness 1994). Milkweeds also contain resinoids, notably galitoxin, several cardiac glycosides, and alkaloids (Turner and Szczawinski 1991).

Any application of the genus is considered dangerous (Foster and Duke 1990, Turner and Szczawinski 1991, Foster and Caras 1994). Cooking apparently destroys the toxins except in highly sensitive individuals (Turner and Szczawinski 1991). In spite of the poisonous chemicals, Bown (1995) and Duke et al. (2003) note that the plants continue to be used medicinally. Duke et al. (2003) give the species a lukewarm recommendation, a single plus.

### ***Asclepias*: Milkweed**

(See preceding entry for etymology)

***Asclepias*.** *Asclepias incarnata* . a. Habit, b. Basal part of plant showing roots, c. Flower. *Drawn by Vivian Frazier.* From Correll and Correll 1972. *Asclepias tuberosa* . From Britton and Brown 1898. *Asclepias viridiflora* . From Britton and Brown 1898. *Asclepias viridis* . From Britton and Brown 1898.

According to Greek legend, the renowned physician and deity Asklepios or Aesculapius was the son of Apollo. He was born in a forested area of Pelion (Pilion) in Thessaly and grew up there under the watchful eye of the wise centaur Chiron who taught him the art of medicine. He thus learned about the properties and uses of herbs, and became a healer. At the summit of his art he tried to extend the limits of human existence and to restore the dead to life. This made Hades angry and afraid that Asklepios would depopulate his kingdom of the dead. Therefore, Hades had Asklepios struck down with a thunderbolt. Yet, the legacy that Asklepios left behind was such that sanctuaries were built in his honor. The shrines were built on carefully chosen sites near streams, near springs, or in the shade of forests—areas of the source of his medicinal plants. There people seeking cures came to pray or to offer sacrifices. Miraculous cures are said to have taken place in these temples to Asklepios. Seven surviving accounts from the 4th century B.C. record numerous cures of the sick at Epidaurus in Peloponnese, the central of those sanctuaries.

Eventually, the disciples of Asklepios founded a temple on Cos and, with Hippocrates, their great master of popular medicine, founded the first school of medicine. Hippocrates and the others at this school continued use of the snake-staff that further symbolized the healing arts of Asklepios. That snake-staff symbol remains today as the caduceus of the medical profession (Baumann 1993).

When Linnaeus named plants in Europe and the other parts of the then-known world, he found that several were widely used in medicines. The most widely used and respected of these he named after the Greek deity, modifying the spelling into Latin *Asclepias*. Oddly enough, the one that is now taken as the focal point to define the genus (the type species) that Linnaeus called *Asclepias syriaca* (the milkweed from Syria), is actually from North America. That error in geography came about because the early botanists who knew the plant in Europe were confused about its place of origin. Both Charles de l'Escluse [Carolus Clusius] (1525–1609), in his history of rare plants and Jacques Phillipe Cornut, in his book on Canadian plants, thought the herbs originated in Syria. Clusius called them *Apocynum syriacum* and Cornut said *Apocynum majus syriacum rectum*. Such was his respect for these authors, and so bad was Linnaeus's geographic ability, that he called them *Ascelpias syriaca*.

Regardless, milkweeds enjoy a long reputation among all people for medicinal application. Among those chemicals in the latex are nitrogen- and sulfur-containing cardenolides with thiasoline/thiazolidine rings. These compounds include voruscharin, uscharidin, and calotropagenin. Leaves contain cardenolides, uscharidin, uscharin, calotropin, calacti, calotropagenin, and calotoxin (Morton 1981, Nellis 1997). Roots contain cardenolide aglycones azarigenin, corotoxigenin, and coroglaucigenin. The cardenolides have especially dramatic impact on the heart, and can either aid its function or stop it dead in its tracks.

Florida does not have a large number of *Asclepias*, but five have recorded uses—*A. humistrata*, *A. incarnata*, *A. tuberosa*, *A. viridis*, and *A. viridiflora*. Because some of these are uncommon, they are not well known. Surely, the best known is *A. tuberosa*, because they grow on roadsides and in open fields (handled separately in the previous entry). The others grow in more specialized habitats (*A. incarnata* in swamps, *A. viridis* and *A. viridiflora* in calcareous ravines or woods), or have less showy flowers.

Of several species known to have been used by prehistoric and historic North American people, only Florida's *A. incarnata* and *A. tuberosa* occur in the record as fiber sources. Gilmore (1931) simply said that *Asclepias* spp. fibers were identified in the Ozark Bluff site in Arkansas. Whitford (1941) found only four examples of *A. incarnata* in Hopewellian and rock-shelter sites as rope and fabric. Whitford (1941) identified *A. tuberosa* in 12 places "from all parts of its geographical range." The species was used by Hopewellian people to weave textiles in Ohio. Bluff-Dwellers in Arkansas left behind a bundle of knotted fibers. Historic people in Massachusetts used the fiber in woven textiles about the time of European contact, and the Iroquois used it to make wampum belts.

*Asclepias humistrata* was in use by people in the Panhandle when Murphee (1965) talked with them. They took the "milk" from milkweed and applied it to warts to remove them.

*Asclepias incarnata* has no recorded uses in Florida, but it was used by the Iroquois (New York), Lakota (Dakotas), Menomini (Michigan), Meskwaki (Iowa), and Ojibwa

(Canada and USA) (Moerman 1998). The Lakota called it *wahinheya ipi'ye'* (medicine used to doctor gopher or swollen glands). Since the species ranges from Quebec to Manitoba and south to Florida and Texas and New Mexico, other people surely also used the plants. We have records of these tribes using the plants in an infusion of roots as a strengthening bath for children and adults, a cold infusion of roots applied to heal a baby's navel, a diuretic decoction (or to treat for too much urine), to treat lame backs, to expel tapeworms, and as a carminative and a laxative. Dried stems, with their strong fibers, were made into cords for tooth extraction. Moreover, flower heads were added fresh to soup or cornmeal mush or dried for winter use (Yanovsky 1936). In addition to normal strengthening, a decoction was taken to increase one's strength to fight witches.

There is little information about use of two other species. *Asclepias viridis* barely reaches Florida and is mostly found from Tennessee to eastern Texas and Nebraska. In Oklahoma (Howard 1984), the Creeks call it *hvtke kaskv* [*hvt'ke-kaskv*, *hutki kathka*] (*hvtke*, white, *kaskv*, milk-exuding) and *tuji h[ɪ]swa* [*tuce heléswy*] (kidney medicine). There was apparently a generic term for all milkweeds—*nochi'* (Chickasaw), *nuchi* (Choctaw), and *noce* [*nóce*] (Muskogee). In English, it is antelope horn (Texas).

Creeks boiled roots to make a tea for kidney problems. Kidney stones were believed to be caused by rabbits; therefore, this is a "Rabbit Medicine." Because they brought this belief of rabbit medicine with them from the southeastern United States, they undoubtedly also took the remedy to Oklahoma (Howard 1984). Florida Seminoles retain the "Rabbit Sickness," but use other plants (Sturtevant 1955).

Although *A. viridiflora* grows from Florida to Texas and New Mexico and north to Ontario to Manitoba, the Creeks also use it. They call it *hutki kaska mabijadi* (*hvtke*, white, *kaskv*, milk-exuding, *mvbe-cate*, red-one), and use it to reduce soreness in an inflamed navel. Plants are boiled in water, and then a towel is soaked in liquid and used to apply the medicine (Howard 1984).

As with other plants, humans are the newcomers in using these herbs. Long ago they were discovered by insects, and evolved a close relationship with butterflies. Not only do many species of Lepidoptera sip nectar from the flowers, but the larvae of the genus *Danaus* feed exclusively on their foliage. That genus includes monarchs (*D. plexippus*), queens (*D. gilippus*), and soldiers (*D. eresimus*). Adult females seek out the members of the genus *Asclepias* and lay their eggs exclusively on them. When the larvae hatch, they feed on the plants and store the poisonous chemicals from their food. When these caterpillars finally hatch into adults, they remain equipped with those same poisonous compounds. Any bird or other animal that is foolish enough to catch and attempt to eat these colorful butterflies quickly learns that they taste horrible. Experiments with uninitiated birds have shown that only a single contact with these foul-tasting insects is enough to teach their potential predators to leave them alone.

There is a totally unrelated butterfly that looks so much like the monarchs that the two are distinguished with difficulty by people. That animal is the viceroy (*Limenitis archippus*). For many years, it was thought that these mimics simply copied the colors and patterns of the monarchs to avoid predators without using bad-tasting chemicals. However, recently in Florida it has been found that there are at least some distasteful viceroys also. By using the mimicry of monarchs and by having some individuals that taste bad, the species achieves added protection from would-be predators because the animals learn quickly to let them all alone (Glassberg 2001).

***Asimina*: Papaw, Pawpaw, or Payaya?**

(From the Virginia Powhatan name *assimin*)

***Asimina reticulata*.** Drawn by  
*P.N.Honychurch.*

Although I was only about 10 when I first saw fruits on pawpaw, I still remember them. On our trips to visit my grandparents in the wilds along the Tennessee River, we had to cross through a creek bottom that supported a wild profusion of plants. At one point beside the trail, there was a shaded grove of small trees scaled down to a youngster's size. Their crowns were only 10 or 15 feet above the ground. Each time I passed them, I felt that the spot was made for me. Then one trip, I found a large fruit, about 5 inches long and 2 inches wide. It was mostly green, but was turning yellow and was spotted with black. When I picked it up, the air was filled with a scent similar to overripe bananas. My parents told me the fruit was a pawpaw, and my dad recited a short verse.

Pickin' up pawpaws, puttin' em in my pocket.  
Way down yonder in the pawpaw patch!

We took the fruit to my grandparents' home and kept it until it ripened. Then, we opened it and ate the sweet, fragrant pulp from around the large chocolate-colored seeds. Years afterward I learned that the plants were *Asimina triloba*.

More than a decade passed before I tasted the first custard-apple or cherimoya fruit (*Annona cherimola*) in Brazil. The same overpowering fragrance and a similar custard-like texture brought back memories of that first pawpaw.

Davidson (1999) wrote about "papaws" that the name was "sometimes spelled 'PAWPAW,' a corrupted name which is, confusingly, often also given to the completely different PAPAYA." If he had looked beyond the edibility of the fruits, he would have found a rich intermingling of Caribbean and eastern North American history, culture, and words.

The original "pawpaw" that Davidson was talking about is *Carica papaya*. By 1598, English-speaking people in the Caribbean were calling these plants "pawpaws" or "papaws." Then, in 1624, Capt. John Smith wrote of the "most delicate Pine-apples, Plantans, Papawes" from Bermuda. The names "papaw-bush," "papaw-thicket," and "papaw-tree" were in use by 1704 for plants being sold in Europe.

However, "pawpaw" had been adopted into English from Spanish *papaya*, which in turn was taken from the Taino *papaya*, a name Oviedo first recorded in 1535 (Coll y Toste 1972). *Papaya* is related to Carib *ababai*, which is cognate with *papaia*, the word used by the Venezuelan Caribs called the Ottomac. By the time Capt. Smith talked about them, this species had been taken around the world to India where its fruits were soon popular.

People settling in eastern North America had either found *Carica* for sale in their homelands or in the Caribbean. When they got to the temperate Americas, they found another tree with a similarly aromatic, sweet fruit. It reminded them of the "papaya," which had already become "papaw," and so that is what they called these different plants.

Although the books say that "papaw" is the preferred name for the North American *Asimina*, and "pawpaw" for *Carica*, I have found just the opposite to be true. Jamaicans, for example, use "papaw" and may not understand you if you say "pawpaw." Similarly, Adams (1971) recorded only the spelling "papaw." From Illinois to Florida all the people that I have talked with used the name "pawpaw" for *Asimina*. If you say "papaw," they think you do not know what you are talking about.

It was later that the scientific community discovered the North American species. After traveling in the Carolinas, Florida, and the Bahamas between 1722 and 1726, English naturalist Mark Catesby published a two-volume folio book containing his paintings and comments. One of the shrubs that he found in the Carolinas he called *Anona fructu lutescente levi scrotum Arietis referente* (the *Annona* with a smooth yellowish fruit that resembles a ram's scrotum). Indeed, the fruit he drew resembles exactly what he called it. Independently, Frenchman André Michaux thought the same, because in 1803 he called the plant *Orchidocarpum* (testicle fruit).

While these perhaps overstimulated European explorers saw one analogy, people also gave the plants other names. Kalm ([1753–1761] 1972) and his mentor agreed with Catesby's generic placement, and Linnaeus ([1753] 1957) dubbed them *Annona triloba*. In 1817 Michel Felix Dunal (1789–1856), a professor at Montpellier, France, moved the species to create *A. triloba*.

By 1760, the names “papaw” and “pawpaw” were being applied to *A. triloba*. By 1796, it was called not only papaw, but also “custard-apple” in Ohio, and later all the way to Texas. Other people call them “fetid-bush.”

These temperate North American plants have edible fruits like their tropical namesakes, but not everyone likes them. Catesby said that the fruit “contains a yellow Pulp, of a sweet luscious taste.” However, he added, “All parts of the Tree have a rank, if not a foetid Smell; nor is the Fruit relished but by very few.” Timothy Flint, another early American, said the fruit pulp “resembles egg-custard in the consistency and appearance. It has the same creamy feeling in the mouth and unites the taste of eggs, cream, sugar, and spice. It is the natural custard too luscious for the relish of most people” (Fernald et al. 1958). Charles Sprague Sargent (1905) wrote: “The sweet and luscious wholesome fruit is sold in large quantities in the cities and towns in those parts of the country where the tree grows naturally.” More recently, the taste of the fruit has been described as “cloyingly sweet” and “nauseating” (Vines 1977). The fruit, which usually falls green, must be stored until ripe before it can be used. People sometimes eat them raw with cream as breakfast food. Others use the fruits baked or as a filling for pies, or combined with eggs, cornstarch, and gelatin for a dessert.

Not only do people eat *A. triloba* fruits, but they have used them in different ways. French botanist André Michaux, who lived in the Americas for several years, wrote: “At Pittsburgh some persons have succeeded in making from it a spiritous liquor; but, notwithstanding this experiment, very feeble hopes can be entertained of cultivating the tree with profit for this purpose.”

This difference of opinion is based at least in part on individual likes and dislikes, but there is some biological basis for it. Taste and texture vary a great deal among plants; some are mild, others strong. Recent study indicates marked genetic variation between populations (Huang et al. 1997, 1998, 2000). Fruits are often compared to bananas in taste and texture, although they are filled with large seeds and are much more aromatic than that tropical fruit. I find pawpaw fruits tolerable in small quantities, but they are not something that I would want often.

Animals, on the other hand, find them delectable. It is hard to find ripening fruits before some wildling has nibbled on them. Birds, gray foxes, opossums, raccoons, mice, gopher tortoises, and squirrels are among the animals recorded as feeding on *Asimina* fruits (Vines 1977).

The more northern *A. triloba* is not the only species in the genus. Florida has eight species, and some extend west to Texas. There is a fossil species known from the Eocene in London, England (Mabberley 1997); however, the genus is now restricted to eastern North America (Kral 1960).

The first record of *A. triloba* came from Virginia where its name in Powhatan was *assimin* (Siebert 1975). Strachey wrote in [1612] 1953 that these people called it *assessemín*, and translated that “a wheat plumb” (Harrington 1955). Siebert (1975) indicated that the spelling was the result of an accidental reduplication during copying from his original notes, and that *assimin* was closer to the original. The word is cognate with Fox *asimini*, Ojibwa *assimin*, and Shawnee *aʔsimi*. The Shawnee even include in their calendar a *aʔsi-mini-ki-sTwa*, “pawpaw month” or September (Siebert 1975). Farther west, the Caddo called it *nashitosh*.

The first record of the species in the Mississippi Valley was by Sieur de La Salle, but he did not give its Algonquian name (cf. *Maclura* for more biographical information). His companion Louis Joliet was the first who attempted the name in his reference to “*des assons, qui sont des petits fruits qui ne sont point en Europe*” (some assons, which are little fruits which do not occur at all in Europe) (Crawford 1978).

French explorer Julien Binneteau later wrote in 1699 that the Illinois called a fruit *asimines* (Crawford 1978), properly spelled *rassimina* (Drechsel 1997). Pierre François Xavier de Charlevoix also described the *acimine* that he saw on his voyage down the Mississippi River in 1721. Kalm ([1753–1761] 1972) said the French in Canada called them *acimine*. With the early French contact, it should be no surprise that it was Frenchman Michel Adanson who named the genus *Asimina* in 1763.

Three of the species are endemic to Florida, *A. obovata* (big-flower pawpaw), *A. reticulata*, and *A. tetramera* (four-petal pawpaw). Of these, *A. tetramera* has the smallest range, found in restricted parts of two counties, Martin and Palm Beach. As a result of habitat loss, the species is considered globally endangered (Coile 2000). The second most widespread species is *A. reticulata*, known as dog apple or Seminole tea in Florida. The other, *A. incana* (flag-pawpaw or gopher plant), also grows in nearby Georgia. Tea is made from *A. incana* roots to treat rheumatism (Murphee 1965).

Curiously, no record has been found of any species having been used by the Seminoles in spite of its common name “Seminole tea.” However, the Seminoles and other Creeks surely used *Asimina* because of the place name Alcovy in Newton and Walton Counties, Georgia. “Alcovy” was derived from “*Ulco-fau*” in the Creek name *Ulco-fau-hatchee* found on an 1818 map. The original Creek meant “pawpaw thicket river” (*oŋko* [orkv, orko], pawpaw, *ofv*, location, *hvcce*, stream). The Choctaw said *umbi*, and the Koasati *ombó*, while their Siouan neighbors in Louisiana said *ephu* (Ofo). The Atakapa, linguistic isolates, said *ol’* (sweet).

Indeed, there is also evidence that Algonquian, Siouan, and Iroquoian speakers throughout the east valued *A. triloba*. The Cherokee ate fruits (Hamel and Chiltoskey 1975), probably in ways similar to their Iroquoian relatives. The Iroquois tribes mashed the fruits into small cakes and dried them for future use. Those cakes were later soaked in warm water and cooked as a sauce or mixed with corn bread (Moerman 1998). Osage called the fruit *to’-zhon-ge*. The tribes through the southeast and central states ate the fruits (Yanovsky 1936).

No records have been found of indigenous people using fruits from other species, but Bartram ([1791] 1958) ate them from *A. pygmaea* when he was traveling in Florida in the 1760s. At Cuscowilla (near present Micanopy, Alachua County) he wrote of “the fruit of the size and form of a small cucumber, the skin or exterior surface somewhat rimose or scabrous, containing a yellow pulp of the consistence of a hard custard, and very delicious, wholesome food.” Presumably, all species have edible fruits.

Few other uses have been recorded, but Sargent (1905) wrote that the fibrous inner bark, “stripped from the branches in early spring is used by fishermen of western rivers for stringing fish.” One must recall that Sargent was a Bostonian, and to him everything west of New York City was “the west.” Hamel and Chiltoskey (1975) later noted that it was the Cherokee, probably among numerous other tribes, who used bark to make strings and ropes.

Those were not simply isolated reports of using the fibers from the bark. The first to record indigenous use of *A. triloba* fibers at the Salts Cave seems to have been B.H.Young's book *The Prehistoric Men of Kentucky* published in 1910 (Jones 1936). Jones said that Gilmore found fiber being used at the Ozark Bluff-Dweller site in Arkansas, but only the seed is listed in his paper (Gilmore 1931). Jones (1936) identified the fibers in both textiles and cords at the Newt Kash Hollow shelter in Menifee County, Kentucky. Whitford (1941) added Bushwick Cave site in Ohio, and identified *A. triloba* fibers in historic Menomini and Potawatomi bags.

As the name Seminole tea suggests, the genus contains a variety of alkaloids and other chemicals. These compounds are known to cause rashes in some people, simply from handling the fruits. Seeds contain the alkaloid asiminine, which is emetic. Bark has the alkaloid analobine, and was once used as a medicine (Millspaugh 1892, Vines 1977). In addition, acetogenins have been found in some species (Woo et al. 1995, He et al. 1996, McLaughlin et al. 1996, Gu and Gordon 1999, Kim et al. 2000). Fruits also contain carbohydrates and lipids (Wood and Peterson 1999).

Another group of organisms learned of the poisonous, but useful, chemicals in *Asimina* long before humans. Those animals are the Lepidoptera, the butterflies. There is a single species of butterfly in Florida that has adapted to use the poisons to its advantage. That butterfly, the zebra swallowtail (*Eurytides marcellus*), uses the chemicals to repel potential predators (Minno and Minno 1999).

Glassberg (1999) recorded both *A. triloba* and *A. parviflora* as the "major foodplants" of larvae of this species, but in southern Florida they may feed exclusively on *A. reticulata*. When that was the only *Asimina* present, and in abundance, the butterfly was equally common. Sometimes there were three or perhaps four broods in warmer areas. Increasing urbanization eliminated the *Asimina* and its butterfly from the Miami area by about the 1950s (Klots 1951). They disappeared from the Boca Raton area in the early 1970s while I was living there. Ranges of the plant and the insect continue decreasing as more and more habitat is changed into parking lots, homes, and buildings. Soon Seminole tea and the zebra swallow-tail will be known from southern Florida only as museum specimens.

### *Asplenium*

(From Latin *splenion* or Greek *asplenon*, spleen; Dioscorides, fl. A.D. 40–80, considered the plants useful in treating maladies of the spleen)

*dubh chasach* [*dubhchasach*] (*dubh*, black, *chasach*, foot, Gaelic)

spleenwort (in use by 1578, although most people of the time preferred the name "miltwast[e]")

*Asplenium erosum* (gnawed away, in reference to basal lobes on leaflets)  
(=*Asplenium auritum*, eared)

*culantrillo* (little coriander, Yucatan)

eared spleenwort (Florida)

***Asplenium serratum***

birdnest fern; New World [wild] bird's nest [bird-nest] fern  
*culantrillo* (little coriander)  
*doradilla de la tierra* (little golden one of the land); *doradilla de las Antillas* (little golden one of the Antilles); *doradille en scie* (saw-toothed little golden one)  
*feto macho do Pará* (male fern [*Aspidium felix-mas*] of Pará, Brazil)  
*lengua de vaca* (cow's tongue, Peru)  
*oreja de burro* (donkey's ear, Oaxaca)  
tooth-leaved spleen-wort

***Asplenium trichomanes*** (hairly)

common spleenwort  
*doradille chevelue* (hairly little golden one, Quebec)  
English maidenhair (in use by 1562); maidenhair spleenwort (by ca. A.D. 1400 the name "maidenhair" was being applied to these ferns; in a publication dated between 1400 and 1450, it was called "Maydenheer or watirwourt, *capellis virginis*"; by 1837, the name "maidenhair spleenwort" appeared in books, combining names from common usage to distinguish genera)  
*polytrichon* (many-haired; in use by 1562 in English, but based on an old Greek name)  
*svartburkne* (*svart*, black, *burkne*, fern, Norwegian)  
water-wort ("watirwourt" was in use between 1400 and 1450; used by Gerarde in 1597)

Originally this plant was used to treat the spleen, at least in Europe. One of the first records we have of spleenworts was left by Leonard Fuchs (for whom the cultivated plant *Fuschia* is named). He recorded names for these plants in his 1542 herbal—German *Hirsungen*, Dutch *hertstonge*, French *langue der cerf*, Italian *hemionite*, and Spanish *lengua de ciervo*. They all translate to the same meaning as the English name he listed—"Hartis tunge" (Hart's tongue). He wrote that Pliny (A.D. 23–79) called the plant *splenion* (spleen, Latin) and Dioscorides (fl. A.D. 40–80) said *scolopendrio* (a centipede). We now call that plant *A. scolopendrium*.

The next usage of the name was in Henry Lyte's 1578 translation of herbalist Rembert Dodoens's *Cruydeboek* when he wrote of "spleenwort or milt-wast." However, he and Fuchs were simply formalizing a usage of many centuries standing.

"Wort" is an English word, albeit of archaic usage and now mostly hidden in common plant names. It simply means herb or plant. Yet, the dominant name in English from Dodoens's time until the 1700s was "miltwaste" (again English, milt=spleen, waste=refuse, or refuse from the spleen). Dodoens himself said: "This herb is called...in English... Scaleferne, Finger ferne, and Myltewaste." Finally, those names dwindled in popularity, and spleenwort became the appellation of choice. In Italian *Asplenium* became *asplenio*, in Portuguese *asplénio*, and *asplénie* in French, little changed from the Latin source. In modern German the genus *Asplenium* became *Streifenfarn* (striped fern). *Hartzungen* now is applied to totally different plants.

Several species in the genus grow in Florida, but two with records of use are *A. erosum* and *A. serratum*. Both are considered endangered in the state (Coile 2000), but extend into the tropics where they are still frequent in a few areas. However, even those areas are being affected by human population growth, and are in danger of being destroyed.

*Asplenium erosum* is used along with several others for baths to overcome fevers and as a cure-all in northwestern Venezuela (Pittier 1926, Morton 1981).

However, the species with the most recorded uses is *A. serratum*. In Haiti, the leaves and rhizomes are powdered and made into a decoction or sweetened syrup that is taken to relieve problems of the liver and spleen (Liogier 1974). The same medicine is also used against diarrhea and spasms of hysteria. Some say it is used to banish nervous tics.

In Cuba, a decoction of *A. serratum* is reputed to dissolve calcifications in the liver, and is recommended for pulmonary inflammation and bronchitis (Roig 1945). People in northwestern Venezuela employ an infusion of various species, including *A. serratum* and *A. erosum*, among others, for bathing to overcome fever. Duke and Vásquez (1994) report that in the upper Amazon *A. serratum* is called *lengua de vaca* and used to treat liver diseases.

Some other American species have recorded uses. These include *A. pumilum*, from Yucatán, where it is called *culantrillo* (little coriander) or *sisil-ch'en* [*sisil-tunich*, *zizalchen*] (Mayan, Yucatan). In North America, the Cherokee of western North Carolina and northeastern Georgia used at least two species. *Asplenium rhizophyllum* (walking fern) was used to create a compound to treat swollen breasts, and a decoction of the plant was taken as an emetic (Hamel and Chiltoskey 1975, Moerman 1998). This species, as with all those recorded, is considered astringent (Hocking 1991). Similarly, a decoction of maidenhair spleenwort (*A. trichomanes*) was taken to regulate menses, an infusion was used to treat breast diseases and “acid humors,” to relieve coughs, and for liver problems (Hamel and Chiltoskey 1975).

### *Aster*

(Latin and Greek *aster*, a star, referring to the shape of the radiate heads)

aster (in use by 1603 in English; cognates include *aster* (French), *Aster* (German); *asters* (Norwegian); *astro* (Italian))

cod-wort (scrotum plant, in use by 1706; the Teutonic word “cod” was simultaneously applied to the scrotum, a long bag, and the outer covering of any fruit or seed ca. A.D. 1000)

daisy (Chaucer spelled the word “daysyes” ca. 1385; this is what we now call *Bellis perennis*; later the word was applied as a generic term for all members of the Asteraceae)

*etoille* (star-shaped, in use by 1549, French)

fall rose (Ohio)

frost-flower [frostweed] (Maine, New Brunswick, New Hampshire)

goodbye-summer (North Carolina)

*inguinaria* (from Latin *in Inguine*, because of use on sores of the flank, in use by 1557, Spanish)

it-brings-the-fall (translation of name used by “New York Indians,” perhaps Iroquoian)

*malmequer* (you-love-me-badly, Portuguese)

Michaelmas daisies (this festival celebrates the Archangel Michael; originally, the name was applied to a British species; it was given to the American plants when the Gregorian calendar was introduced because it brought the feast forward by 11 days to 29 September, the time of flowering)

*neòinean* (strictly applied, *Bellis perennis*; otherwise generic for *Aster*, Gaelic)

sharewort [sharewurte, shareworts] (“share” is an old name for flank, as this name was used by Henry Lyte in his 1578 translation of Dodoens’s *Cruydeboek* of 1554, and by John Gerarde in his herbal of 1597)

starwort [starwoorts, steerwort] (star-herb, used by H.Lyte in his 1578 translation of Dodoens’s *Cruydeboek* of 1554; later by John Gerarde in his herbal of 1597)

*Sternkraut* (star herb, used by Fuchs in 1542, German); *sterrecruyt* (star herb, in use by 1549, Dutch); *stjerne* (star, Norwegian)

***Aster carolinianus*** (of Carolina)

climbing aster

*ʔintayhî* [*wahofe* *entayhe*, *waaho(th)e entahe*] (water moccasin’s bed, Mikasuki)

***Aster dumosus*** (bushy)

[bushy, rice-button]-aster

frost-flower

starwort

***Aster lanceolatus*** (lanceolate, or with leaves resembling lance points)

[panicked, tall white, white panicle] aster

***Aster lateriflorus*** (with one-sided flower-clusters)

[calico, California, cascade, hairy-stemmed, side-flower, starved, white woodland] aster

devil-weed (West Virginia)

farewell-summer (West Virginia)

nail-rod

old-field sweet (West Virginia)

old-Virginia stickweed (West Virginia)

rosemary (a confusion or comparison with *Rosmarinus*, Maryland)

Tradescant’s aster (translation of an synonymous name, *Aster tradescantii*)

white-devil (West Virginia)

wire-weed (West Virginia)

***Aster linarifolius*** (with leaves resembling *Linaria*, toadflax)

[flax-leaf, flaxleaf aster, savory-leaved, stiff-leaved] aster

*ionactis* (violet ray or beam, Greek)

[pine, sand-paper]-starwort

***Aster praealtus*** (very tall)

[tall, will, willow-leaf, willowleaf] aster

Linnaeus ([1753] 1957) recognized 30 species of *Aster*. Since that time, *Aster* has grown to a genus of about 250 species even with the recent removal of several species groups (Mabberley 1997, Diggs et al. 1999). Neson (1994) redefined the genus such that *Aster* is a group of ca. 180 species confined to the Old World, and he put the New World species in 13 genera. Because a consensus has not yet been reached on generic limits, many authors continue to use the old definition of *Aster* (e.g., Wunderlin 1998, Diggs et al. 1999).

John Gerarde ([1597] 1975) said that the asters were called *inguinalis*, because a poultice of the plants was used on “botches, imposthumes, and vererous bubones (which for the most part happen in *Inguine*, that is the flanke or share) doth mightily maturate and suppurate them.” Culpeper (1653) agreed, including two species of *Aster*. For what Culpeper called *A. hortense* (the cultivated aster), he said: “The leaves are only used, which are commended against buboes and swellings in the groin.” The sea-starwort (*A. tripolium*) he recommended as “cooling, and good for burns, scalds, and inflammations, in any part. The seed is narcotic and soporiferous, and rarely used.”

*Aster caroliniensis* was used by the Seminoles to treat “Snake Sickness” (itchy skin) (Sturtevant 1955). Leaves of this aster along with a whole *Paspalidium* plant, and *Ludwigia* roots were boiled in water (see also *Paspalidium*, *Ludwigia*). Patients drank the mixture and steamed their bodies to achieve the cure.

The only records found of *A. dumosus* being used are among the Tewa of New Mexico. They ate the fruits (Moerman 1998).

*Aster lanceolatus* was considered a febrifuge among the Iroquois (Moerman 1998). Matilda C. Stevenson’s *Ethnobotany of the Zuñi* recorded: “The entire plant is ground between stones in the fraternity chamber of the *Shu’maakwe*, at noon during the elaborate ceremony of the preparation for the fraternity of medicine in August, by the *A’wantsi’a* (‘great mother of the fraternity’).... This medicine is in the exclusive possession of the *a’kwamosi* (director of medicine), and is used only on the faces of the personators of the *Shu’maikoli*, patron god of this fraternity” (Coffey 1993). She added that the plant was also used to treat arrow or bullet wounds. For nosebleeds, the blossoms were crushed and sprinkled on live coals, and the smoke inhaled.

The Meskwaki boiled the leaves of *A. lateriflorus* as greens. They also used the entire plant as a smoke or steam bath to cure mental problems (Hocking 1997, Moerman 1998).

The Cherokee made a tea of *A. linarifolius* to relieve fever; they also drank it to stop diarrhea (Hamel and Chiltowsky 1975). When they had pains of various kinds, they made a poultice of the roots and applied them to the area that was hurting. The Cherokee also sniffed the liquid from the roots to stop catarrh (Hamel and Chiltowsky 1975).

The Meskwaki used *A. praealtus* to revive an unconscious patient (King 1984). The Navajo used another variety to treat snakebite, as an eyewash, to stop stomachache, and to cure internal injury (Moerman 1998).

### *Athyrium*

(From the Greek *athyros*, doorless, the growth of the sporangia only tardily forcing back the outer margin of the indusium)

#### *Athyrium felix-femina* (lady fern)

*a'sawan* (Ojibwa)

*fougère femelle* (lady fern, Quebec); lady fern

*nonagonawusk* (milk weed, Potawatomi)

*Athyrium* is a genus of about 180 species throughout the world (Kato 1993). North America has two species, the western *A. alpestris*, and *A. felix-femina*. Although the species was considered exotic by Fernald (1950), it is now thought to be circumboreal (Kato 1993).

Moerman (1998) found documentation of use among the Iroquois, Meskwaki, Ojibwa, and Potawatomi in the eastern part of North America. In the west, the ferns are also used by the Bella-Coola, Cowlitz, Hesuiat, Karok, Kwakiutl, Makah, Nitinaht, Okanagan-Coville, Quileute, Quinault, Suswap, and Thompson.

The Iroquois mixed it with aster (*Aster novaanglae*) for intestinal fevers, with other ingredients to keep a woman's water from breaking prematurely before giving birth, and men used it to treat venereal diseases. The Meskwaki made a medicine to treat breast pains associated with childbirth. The Ojibwa used it as a diuretic, a healing powder on sores, and to induce breast milk flow in women. The Potawatomi also used it for breast problems (Smith 1933). The Potawatomi name for the fern reflects that usage (Core 1967).

Hocking (1997) considered lady fern anthelmintic, a remedy for intestinal fevers, of help in preventing premature births, and venereal disease. Foster and Duke (1990) note that an antigout potential has been identified in the related *A. mersorum*.

### *Atriplex*

(Ancient Latin name used by Pliny, A.D. 23–79, for the orach, the kitchen vegetable, *A. hortensis*)

*armoles* (Portuguese); *armuelle* (Spanish)

*atraxaxi* (*atra*, black, *phaxys*, braid, Greek, Fuchs 1542); *atriplice* (from Latin *atriplicem*, Italian); orach [*orache*, *orage*, *orech*, *orege*] (from French *arroche*; in use in English by ca. 1430); *arasche* (Anglo-French by ca. 1265; this gave rise to *arche* in English, cf. Turner 1568); *arroche*

(French dialect designating plants of salty soils, from Latin *atrapiça* or *atripica*, from *atriplex*, altered from Greek, *atrapphaxys*)

*belle dame* (pretty woman, French); *bonne dames* [*bonnedame*] (good woman, French, 1549)

*chamiso* (New Mexico)

*melde* (Dutch from 1549); *Melde* (German; formerly *Milten* and *Molten*, cf. Fuchs 1542 and Turner [1548] 1965); *melde* (used for family, Norwegian); *melden* (Dutch, cf. Harriot [1590] 1972)

*praiseach-mhin chladaich* (smooth broth of the shore, Gaelic)

salt-bush (an allusion to the plants growing in areas high in salt, whether near the ocean or on inland salines; in use by 1863)

shad-scale (for shad; see *Amelanchier*; presumably, the enlarged bract-like sepals reminded people of the scales on shad, *Alosa sapidissima*)

***Atriplex pentandra*** (with five anthers)

crested salt-bush [crested saltbush]

sea-beach orach [seabeach orach]

The European orach, *Atriplex hortensis*, grows all around the Mediterranean coast, and as far east as Siberia. These herbs, which reach 7 feet (2.13 m) with arrowhead-shaped leaves, were cultivated as a green vegetable as we now use spinach (*Spinacia oleracea*) from the time the Mediterranean civilizations began (Davidson 1999). The plants were mentioned by Dioscorides (fl. A.D. 40–80), Galen (A.D. ca. 129–ca. 199), Pliny (A.D. 23–79), and Simeon Seth (fl. A.D. 1070–1080). Orach was used in England in the 1500s, but became less popular as the availability of spinach increased.

Europeans certainly would have recognized the several species of *Atriplex* that grow in the eastern United States as being like the Old World orach (but see *Chenopodium* for different taxonomic views). Fernald et al. (1958) comment on two species eaten in New England and eastern Canada. However, no records have been found of eastern tribes eating *Atriplex*. All of the records seem to be of western tribes. Moerman (1998) listed 18 species that were eaten by people from the Gosiute of the Great Basin west to California.

Those same tribes used several species for medicine and dyes (Curtin 1947, Moerman 1998).

### *Aureolaria*

(From diminutive of Latin *aurea*, *aureola*, golden, probably with Greek *aria*, oak; maybe Rafinesque was alluding to the color of the corollas, and the fact that the plants were hemiparasitic on oak roots)

false foxglove (false to distinguish this from the true “foxglove,” *Digitalis*; foxglove is derived from Old English *foxes glofa*, first recorded ca. A. D. 1000; related to *revbjelde*, fox bell; that the tubular corollas are similar to thimbles or fingerstalls is obvious; unexplained is how they became associated with foxes)

*Klapperkopf* (rattle head, German)  
oak-leech [oakleech] (the name alludes to the tapping of *Quercus* roots by *Aureolaria* to obtain liquids and dissolved nutrients)

*Aureolaria flava* (yellow, the flowers)  
[downy, smooth, wild, yellow] false foxglove golden oak (a literal translation of the genus; or was this where Rafinesque got the genus?)

*Aureolaria pedicularia* (resembling *Pedicularis*) fernleaf yellow false foxglove; yellow foxglove fever weed (alluding to the use in lowering fevers) lousewort (because it resembles *Pedicularis*)

*Aureolaria virginica* (of Virginia) downy yellow false foxglove

Fernald (1950) included this genus with *Gerardia*, perhaps at least partly because Rafinesque named it. Now it is thought that there are ten species of *Aureolaria*, with all growing in the eastern United States, and one in Mexico (Mabberley 1997). Most of them are hemiparasitic on the Fagaceae, although they also grow on Ericaceae.

Probably the first record of this plant being associated with people was given by Gilmore (1931). He identified some species in the Ozark Bluff-Dweller site in Arkansas and wrote: "It is not known whether it had any use." These prehistoric people probably used the genus as did historic tribes.

The Cherokee used *A. flava* and *A. pedicularia* to halt dysentery and in treating stroke (apoplexy) (Hamel and Chiltoskey 1975). The Chickasaw considered *A. pedicularia* emetic but also used it as an antiscorbutic (Campbell 1951). The Cherokee also took a decoction of *A. virginiana* to treat dysentery (Taylor 1940).

Porcher (1863) wrote of *A. flava*: "This plant, it is said, will prevent the attacks of yellow and other flies upon horses; probably owing to its great viscosity.... It is pubescent and highly viscous. It has very little taste, unless chewed for some time. Upon a subsequent examination (1862)... I find that each hair with which the plant is covered secretes from a gland at its summit a tenacious, gummy substance, to which insects may adhere. Under the microscope it is an interesting object."

Subsequent practitioners considered *A. flava* a stimulant, diaphoretic, and sedative (Hocking 1997). *Aureolaria pedicularia* was considered antiscorbutic, diaphoretic, sedative, and emetic, and was used to treat fever (Hocking 1997).

*Aureolaria virginiana* was considered an antidote against venomous snakes (Hocking 1997). However, the first record of using this genus against poisonous snakes probably came from Stephen W. Williams in 1849, when he listed *A. flava* (under the synonym *Gerardia quercifolia*) as a Sioux remedy (Vogel 1970). Because Hocking (1997) did not give his sources, the use of *A. virginiana* remains uncertain.

Members of *Aureolaria* are said to be poisonous (Diggs et al. 1999). Presumably, that comes from their iridoid (aucubin) compounds. Those chemicals are sequestered by the Baltimore checkerspot (*Euphydryas phaeton*) butterflies (Mabberley 1997). Since these orange and black butterflies also feed on *Chelone glabra*, that is probably correct because they, too, are loaded with toxic chemicals (Glassberg 1999).

***Avicennia*: Black Mangrove**

(Named for Iranian philosopher and physician Abu Ali Al-Husayn Ibn ‘Abd Allah Ibn Sina, 980–1037, alias Avicenna)

Throughout the world, trees growing near the ocean margin in salty water are called mangroves. Regardless of species and language spoken where these trees grow, people have assigned colors to different kinds. The colors are not always the same among different language groups, but they use colors as modifiers to distinguish among the species.

The origin of “mangrove” in English is obscure. Some attribute it to Spanish *mangle* (thicket), first applied by Gonzalo Fernández Oviedo in 1535. Cognates, appearing somewhat later in the 16th century, occur in Portuguese as *mangue*, and in French as *manglé*. Yet others attribute all of these to the now extinct Malay term *mangi-mangi* denoting these

***Avicennia germinans*. Drawn by  
P.N.Honychurch.**

plants. Regardless, the mangle (derived from French by ca. 1361) of branches on many of these plants caught the imagination of people who saw them. Perhaps they were just appalled at the prospect of climbing through the jungle gym of branches and roots to get ashore.

Black mangrove (*Avicennia germinans*) is the name most commonly applied to this American species. However, other species in the genus in the Old World also have the dark bark and foliage that, especially when viewed from a distance, apparently inspired this name. Among the names referring to the black color are *ahilo:clo:cî* (black tree, Mikasuki), black bush (British Antilles), black mangrove (Florida to Panama), blackwood bush (Bahamas), *itolastilâsti* (eto, tree, Ivste, black, Creek), *mangle negro* (black mangrove, Cuba, Puerto Rico, Panama, Sonora, Yucatan), *mangle prieto* (black mangrove, Cuba, Colombia, Venezuela), and *manglier noir* (black mangrove, Haiti, French Guiana). Some do not think they are black, but gray, as in *mangle gris* (gray mangrove, French Antilles) and *palétuvier gris* (gray mangrove, French Antilles). Even in some of the same regions, people attribute other colors to the trees. Hence, they are *mangel blanc* (white mangrove, French Antilles), *mangel blancu* (white mangrove, Dutch Antilles), *mangle blanco* (white mangrove, Veracruz, Oaxaca, Tabasco, Yucatan, Puerto Rico, Cuba), *mangue bronco* (white mangrove, Brazil), *palétuvier blanc* (white mangrove, Haiti, French Guiana)—or, even *mangle amarillo* (yellow mangrove, Spanish), and Portuguese *mangue amarelo* (yellow mangrove, Brazil). The Mayo of Sonora simply say they are *ciali* (green).

No one can look at the trees long without noticing the accumulations of salt, both on the bottom of the leaves and on the rhizophores (root extensions like fingers below the trees). The salty aspect is recorded in *árbol de sal* (El Salvador), *madre de sal* (mother of salt, Chiapas), *palo de sal* (salt tree, Costa Rica, Nicaragua), *salado* (salty, Puerto Rico), salt pond tree (Dutch Antilles), and saltbush (USA).

Other people note associations with animals and the trees. Some of the associations are obvious, and others are not. For example, there is *chifle de vaca* (cow whistle or song, Puerto Rico). Who ever heard a cow sing or whistle? Perhaps this name, like others for some plants, simply indicates a nonsensical sense of humor. Other names are more easily understood across cultures. Because the trees grow on the margins of the ocean, they are in or near places where sea turtles nest, hence green turtle bough. Along coastal northwestern South America, the few remnants of mangroves remaining often have dozens of fat, lazy iguanas lying on the branches or nibbling young growing leaves and buds. There they are called *iguanero* (place for iguanas, Colombia) or *mangle iguanero* (iguana mangrove, Ecuador). I would bet that *siete cueros* (seven skins, Puerto Rico) refers to the number of animal skins that one might tan with the tannin extracted from a black mangrove. Finally, in Brazil they are called *siriuba* [*seriba*, *ciriuba*] (crab-tree in Tupi). There are almost always crabs of two or three species burrowing near the inland regions occupied by these trees, and this name shows that observation by inhabitants in that region.

In addition, there are names that fall into several categories. These are mostly indigenous names that have not been translated, although some interesting analogies are also included. No meanings have been found for *aili* (Cuna, Colombia), *apari'ë* [*apario*, *apalioe*, *apariyu*] (Carib, Suriname), *ishtatén* [*istatén*] (Mayan?, El Salvador), *koroda* (Arawak, Suriname), *parwa*, and *puyequé* (Sinaloa). Some of those making different observations are *algarrobo* (usually applied to mesquite, *Prosopis*, Fabaceae); this might be a mistake. Perhaps *bois de mèche* (wick tree, French Antilles) indicates a usage that no one has recorded otherwise. The large size of old trees may be hidden in *calumate* [*columnate*] (variant of *columna*, column?, Costa Rica). In Ecuador, I have seen dugout

canoes large enough for four or five people made from the trunks, and their forests are almost gone now. It is known that old trees grow to remarkable sizes. Someone from a temperate zone must have given the name *chêne* (oak, Guadeloupe). The name *courida*, also given as *cruda*, possibly comes from *couro* (skin in Portuguese, in reference to bark, Guyana). This may be another reference to tanning properties. The name *guapirá* comes from Tupí, meaning “bitter to eat.” Finally, some call them limewood (Trinidad).

Before Linnaeus used this name, authors in India called them *Anacardium* (a name we now use for the cashew tree, an American native) and *Oepata* (an indigenous name on the Malabar coast of India). *Avicennia* contains about eight species, with half of them in the Old World tropics. In addition to our *A. germinans*, the American tropics also have *A. bicolor* and *A. schaueriana*.

Throughout its range, black mangrove is visited by honeybees. Several sources indicate that it is the major contributor to “mangrove honey,” although Tomlinson (1986) was somewhat dubious about that. Surely, the most common use of all species in the past has been as a source of wood and fuel, especially charcoal. The wood of some species is prized, but ours tends to crack easily upon drying. Still, it has been used for posts and flooring. The bark not only is used in tanning animal skins, but also provides dyes. Black mangrove gives a black dye, and some of the Asian species yield a brown dye prized for batiks. Medicinally, *A. germinans* is considered a powerful astringent and, given the tannin content, that is surely true. That same tannin would account for the antihemorrhagic and antidiarrhetic properties claimed for the medicines.

An obvious trait of the trees is the salt on them. This salt has been utilized by people throughout its range where the leaves are gathered as the source. Salt gathers on other parts of the plants, largely roots, but is less convenient to harvest. While the Seminoles had names for the trees, they claimed no use for it. However, given their nomenclature of this and white (*Laguncularia racemosa*) and red mangroves (*Rhizophora mangle*), that seems dubious.

There has long been disagreement about whether or not black mangroves should be put in the Verbenaceae, where they were initially placed, or removed into their own family, the Avicenniaceae. Tomlinson (1986) and others who have studied the group are convinced that they should be in a distinct family. Supporting that view are distinctive wood anatomy (secondary thickening), leaf anatomy, placentation, incipient vivipary, and seedling morphology. However, the TROPICOS Web site (Solomon 2003) lists the genus in the Verbenaceae. Since the Verbenaceae itself has been undergoing reorganization by the molecular genetic students, the situation, like so many in biology, remains debated and debatable. Unlike the “hard” sciences of chemistry and mathematics, biology remains open to interpretation and distinctive views. There is no single answer to many biological problems, in part because of human bias, differences in interpreting the same data, and because “Mother Nature” has solved problems in a jury-rig manner. That uncertainty is what makes the whole topic of biology an anathema to some, and a delight to others.

## B

### ***Baccharis*: Saltbush**

(Perhaps from *Bacchos*, the Greek god of revelry, but see discussion for alternatives)

***Baccharis halimifolia*. From Britton  
and Brown 1898.**

When I first moved to Florida in 1970, I began learning about the shrub people called saltbush. As the summer finally changed to fall, I began seeing white-topped bushes everywhere. It soon became clear that these shrubs thrived best where the soil was moist but not wet. So, I would often find them in the edges of marshes, swamps, prairies, and other wetlands. As more land was cleared and drainage continued, the shrubs began appearing in more places that ceased having standing water. When I finally was able to fly over southern Florida in a small plane at low elevation in the fall, I was astounded to see the quantity of white-topped saltbushes that occupied the inner ponds on cypress domes, marshlands, wet prairies, and swamp edges. Then, when I got back to the plants on foot, I discovered the almost infinite number of seeds that each produced. It was no wonder that they were a dominant feature of the landscape. With that many seeds it would be more remarkable if they were not everywhere.

Now that I live in Arizona, I still see saltbushes everywhere. The species here are not the same as in the Caribbean wetland borders, but they are still in moist places. They come up beside sprinkler outlets near my plants, beside my barrel cacti (*Ferocactus wislizeni*), by the wall in my back yard, in desert washes and arroyos, and on periodically moist roadsides. The impression that they produce phenomenal numbers of seeds is enhanced by the plumed seeds floating in the air when I walk outside, and when I sweep my front porch to remove the drifted cottony masses.

Saltbushes belong to the genus *Baccharis*. This genus originally was proposed by Linnaeus for a dominant species in Florida, *B. halimifolia*. There are two opinions about the source Linnaeus used for these plants, which is exactly what he delighted in—multiple meanings. The standard answer is that the genus came from *Bacchos*, the Greek god of revelry. This is the interpretation given by botanists Fernald (1950), Munz (1973), and Correll and Correll (1982). Yet, what the Greek god of wine has to do with a fragrant American plant where wine was unknown before Europeans arrived is never addressed.

Another view has recently been published. This interpretation is offered by physician-historian Umberto Cuattrocci (1998). He says the name comes from “Greek *bakkaris*, an unguent made from ‘asaron’; *bakcharis*, an ancient Greek name used by Dioscorides (fl. A.D. 40–80) for sowbread,” which is *Cyclamen hederacifolium* (Primulaceae). Everyone knew that the name was applied to some other plant before Linnaeus, but Cuattrocci does not even mention a connection with *Bacchos*. Perhaps they are both correct interpretations, because the original *bakkaris* was a plant with a fragrant root that was used to add another flavor to wine. *Bacchos* (and Linnaeus) would have liked that.

There is little to connect saltbush with wine in North America, but the common names point to formerly widespread use as a medicine. In English *B. halimifolia* is called consumption weed (used to treat consumption or tuberculosis). The second most common name is groundsel bush or groundsel tree. That name is more complicated, but still may reflect medical usage because the etymology of the term “groundsel” is unclear. The second element seems to be based on Old English *swelgan*, to absorb, swallow. It appears that the earliest reference to groundsel was in the 10th century as *grundaeswyligiae*, which apparently meant “pus-swallower.” This is thought to be an allusion to the medicinal uses in Europe of the related genus *Senecio*. That genus contains numerous alkaloids and continues to be used as an herbal medicine today. Groundsel bush then means a bush that might be used medicinally like the groundsel. Similarly, sea sage, silver sage, and silverling (sometimes applied only to *B. glomeruliflora*, other times also to *B. halimifolia*) suggest medical plants.

*Baccharis* is also lowbush merkle, sea muckle, and sea myrtle. Those are names based on “myrtle,” the common name for *Myrtus communis* (Myrtaceae) a common medicinal shrub in southern Europe. Use of myrtle as a medicine goes back in English literature to a handbook for surgeons written about 1400, and even older in Latin and Greek. So, “lowbush” and “sea” are compound names that distinguished these New World plants from familiar Old World medicines.

There also are indigenous names for these plants. In Florida, the Miccosukee called them *i:fâyhô:mî* [*i:frâyhô:mî*] (like dog shot, or *ifilayko:mi*, like dog feces?, Mikasuki). No use has been recorded, but the fact that they even had a name for them suggests that they probably were used. In Latin America, the shrubs are called *bajaquilla* (probably an indigenous word), *chilca*[*chilec*] (indigenous name, Colombia), and *ciro* (probably wax, *cirio*, Colombia).

In the southeastern United States, root decoctions are taken for colds and stomach pain. *Baccharis halimifolia* contains baccharine, and is used in domestic medicines against respiratory diseases and for fever. Sometimes, leafy branches are boiled with cudweed (*Gnaphalium obtusifolium*) and used as medicine for colds. Branches boiled with the tops of buttonbush (*Cephalanthus occidentalis*) also are given for colds and whooping cough (Morton 1974). Several species contain glycosidal saponin and are

poisonous to farm animals (Dayton 1937). Lewis and Elvin-Lewis (1977) note that almost all members of the Asteraceae contain sesquiterpene lactones, and many of these are cytotoxic. Among those known to contain these lactones is *B. pteronioides* (*yerba-de-pasmo*). It is likely that these poisons are also among the active compounds in the medicinal mixtures.

Morton (1974) noted that the species previously was used more often. Physician Porcher (1869) wrote: "This plant is of undoubted value, and of very general use in popular practice in South Carolina, as a palliative and demulcent in consumption and cough. I have seen it used with advantage, and have often heard those employing it confess a benefit from it. A strong decoction of the root may be drunk several times a day. It is slightly bitter and mucilaginous to the taste." Few people now are even aware that it was ever used as medicine.

One more recent application is by beekeepers. The genus as a whole seems to be prized by alien honeybees (*Apis mellifera*), native bees, and butterflies. Honey from these plants has been sold seasonally from at least South Carolina to Florida. One need only sit beside the plants for a few minutes to see that hundreds of individuals of dozens of species of insects visit the flowers.

Yet another use of these plants that has disappeared from the United States is bundling the branches for brooms. Before brooms were commercially available, people all over the world made their own from whatever plants were handy. Those with abundant small, stiff branches were best, and *Baccharis* is particularly good. This usage goes all the way back to the Aztecs of Mexico who called one of their species (*B. ramulosa*) *tepopotl* (*popotl*, brush, Náhuatl). Other species in Mexico are called *escoba del monte* (countryside broom) and *escobilla* (little broom). One Mexican species is even called *limpiatuna* (prickly pear cleaner). Prickly pears are commonly eaten in Mexico, and it is not unusual to be served peeled fruits, green or ripe, in restaurants for breakfast. Since these fruits have small, barbed spines on them (called glochids), they have to be removed before eating. Usually, it is a good idea to remove the spines even before trying to peel the fruits. Some people have used brushes of *Baccharis*, but many "modern" rural people now sometimes use old pieces of cloth that they drag over the fruits before attempting to remove them from the plants.

Unfortunately, common names are not like scientific names, and apply to only one kind of plant. There are actually other species of plants in Florida (and elsewhere in the Americas) called "saltbush." Mostly, that name applies to the genus *Atriplex* (Amaranthaceae), and there are two species that grow along the Florida coasts. A totally separate derivation of the name has resulted in both *Atriplex* and *Baccharis* being named "saltbush." That route involved the tendency to grow in saline or salty areas, particularly near the ocean. However, elsewhere either genus may grow in areas with internal drainage that forces the water to evaporate and leave behind dissolved salts. Therefore, in Florida one may find *B. angustifolia* growing along with *Atriplex* on the flats near the ocean. Both are saltbushes, and they are distantly related and "united" only by ecology and common names.

What seems to be an "invented" name (although it was used by John K. Small in 1933) for *B. angustifolia* is "false-willow." Newer books call it "saltwater falsewillow," presumably to distinguish it from other species. The ecology is correct, but no Florida country person will have any idea what you are talking about if you ask for that plant.

**Bacopa Water-Hyssop**

(From *bacopa*, a French Guiana Carib name)

***Bacopa caroliniana*.** From Institute of Food and Agricultural Sciences.

To understand some of the complexities of how water-hyssop (*Bacopa monnieri*) came to get its common name, I must begin with a digression. Unless you are thoroughly familiar with the paraphernalia of Catholic Church rituals, or conversant in Hebrew, you will not understand the contorted history that led to an American plant being called “water-hyssop,” an Old World name. Even if you are completely familiar with the Catholic Church or Hebrew, you still may not know the entire story.

First, *hyssop* is not derived from Greek, Latin, or even Germanic languages, but from Hebrew. The term was used in the Bible, and the Hebrew word is *esov*. This word in the Bible is translated as “hyssop,” but earlier variants show the evolution from the original to the final form. Greeks, about A.D. 1000, first adopted the word and transcribed it as *ussupos*. Beginning much later, it was spelled in Old English as *ysopo*, *ysope*, *ysop*, *isop*, to finally “hyssop” in modern English. There has been debate about the identity of the original *ezov*, but that has been resolved to my satisfaction by biblical scholar botanist Michael Zohary (1982). He argues that, since the plants known botanically as *Hyssopus officinalis* do not grow, or only rarely do, in the region of the Bible, then they were unlikely to have been the important species used by Jews in the ancient purification rituals. He argues convincingly that the common plant *Origanum syriacum* must have been the *ezov* of the Bible, particularly since that remains its modern Hebrew name. Both plants are mints, but Linnaeus, who named both in 1753, could hardly have realized that what he called *Hyssopus* was not common in the Holy Land and *Origanum* was. Indeed, it is well known that Linnaeus was a poor geographer. For example, Linnaeus could not seem to understand the differences in the New World among Canada, Carolina, and Florida (Austin 1993).

In biblical times and now, bundles of *ezov* are used to anoint and purify alters and other items. When the comparatively young Catholic Church came into existence, it retained the purification ritual, but changed the details. Instead of bundles of *ezov*, Catholic priests use a holy-water sprinkler to bless items and people. They call that sprinkler a “hyssop,” probably without knowing that it was named for an original bundle of mints used by Jewish rabbis.

Once the word *hyssop* was established in English, it became incorporated into common names of a series of plants that reminded people of the original mint. By the early 1500s, the literati of northern Europe knew how to distinguish hyssop from other similar medicinal herbs, but the knowledge of common people never keeps pace with scholars. Or, maybe it is the reverse, with scholars always being behind. For example, physician Leonard Fuchs’s great herbal of 1542 lists *hyssopus hortensis* [the hyssop of horticulture] as medicinal, and quotes Dioscorides (fl. A.D. 40–80) and Pliny (A.D. 23–79) as earlier users of this plant (Meyer et al. 1999). At the time, the common names of the plant were “gardin hyssop” in English, *Garten Ispen* in German, *ysopé* in Dutch, and *isopo* in Spanish.

Nonphysicians, however, had their own nomenclature for similar species. Among the oldest names recorded are anise hyssop (*Agastache foeniculum*), and bastard hyssop (*Teucrium pseudo-hyssopus*), both true mints (Lamiaceae). There was also giant hyssop (*Lophanthus* sp.). After a while, plants other than mints also became known as hyssops. From Miller’s (1730) *Dictionary*, we also find hedge hyssop (*Gratiola officinalis*, Veronicaceae), wild hyssop (*Verbena hastata*, Verbenaceae), and water hyssop (*Bacopa monnieri*, Veronicaceae). That same water hyssop is one that now grows in Florida, where it retains that old name.

It is uncertain if water hyssop (*B. monnieri*) is native to Florida. Wunderlin (1998) thought it was, as do many others. However, the species was present in India so long that it has Sanskrit names, *brahmi* and *mandūki*. Having Sanskrit names is sometimes taken as evidence that species are native to India. Still, there are numerous cases of plants having pantropical distributions, and being in India does not rule out its also being native in the New World.

Another old American name for *B. monnieri* is herb-of-grace. That name was also applied to *Verbena* in the 1540s, and shows the pervasive importance of several of these plants. Modern names for *Bacopa* show the continued confusion between these two genera with *véronique* and *petite véronique* (French Antilles). Indeed, the name herb-of-grace was given to rue (*Ruta graveolens*) in the 1730s. In Puerto Rico, *Bacopa* is called *yerba de culebra* (snake herb) and in Cuba it is also *verdolaga de costa* (coastal purslane).

*Bacopa monnieri* has also been called *graciola* (derived from Latin *gratia*, because of medicinal value). That confusion is long-standing because Linnaeus put the species in *Gratiola* in 1753. The plants also have been known botanically as *Herpestis monnieri* and *Bramia monnieri*, so botanists and others have confused them. Roig (1945) compared *Bacopa* with the European *graciola* and said it was almost as good a medicine. He attributed purgative and hydragogue properties to both, and noted also that it was used against rheumatism, as a diuretic, against mouth infections, and to treat *escorbuto* (a lack of vitamin C) and catarrh of the lungs. Either Cubans had discovered it independently or they had brought with them a knowledge of the use against rheumatism, because that was

one of the oldest known uses for the plants in India. The plants are also known diuretics (Lewis and Elvin-Lewis 1977).

The herbs have a number of chemicals including brahmine and bacco-side A (Hocking 1997). These compounds have been used as nerve tonics in mental disorders, against psychosis, and for epilepsy (Hindus). In the Old World, they also were used to treat thread-worm.

It is certain that *B. caroliniana* is native. Moreover, this herb has many of the same uses as *B. monnieri*. Yet, because of several distinctive traits, these two are always distinguished from each other by common names. The blue flowers of *B. caroliniana* cause it to be called blue hyssop or blue water-hyssop. When the leaves and stems are crushed, they give off a strong lemon scent, and this resulted in its being called lemon hyssop. To the Seminoles these were *wi:katcahiliswa* (owe, water, *kaccv*, puma, *heleswv*, medicine, Creek), and *okikó:wayikcî* (water puma medicine, Mikasuki). They use the plants as cough medicine and as a sedative against what they termed "Turtle Sickness," trembling, shortness of breath, cough. The species ranges from Virginia south to Florida and west to eastern Texas, so it is endemic to the southeastern United States.

There are other species in the genus that have caught the attention of people near them. *Bacopa* was named by Aublet in 1775, and he took the genus from a Carib name for the French Guiana species. That species was *B. aquatica*, and the French settlers in that country called it *herbe-aux-brulures* (burn herb) and "claim that once applied, it cures burns in a short period of time." Since that time, botanists have found some 56 species in the genus, most of which are native to the Americas (Mabberley 1997).

At least to the Maya of Yucatán, Mexico, *B. monnieri* has long been an important plant. They call it *ya'ax-kach* (*ya'ax*, green, *kach*, place). They know that where *ya'ax-kach* grows, there always is abundant water. And to the Mayas, where there is water, there is life.

### *Baptisia*

(Etienne Pierre Ventenat, 1757–1808, created the genus from Greek *bapto*, to dip in dye)

*baptisie* (French)

*cintó okcáyya ahissî* (*cintó*, snake, *okcáyya*, living being, *ahissî*, medicine, Koasati; given to *B. australis* that they used to make yellow dye)

*Färberhülse* (dyer's pod, German)

*ke-u'-gthe hi* (Osage)

*poafachi* (this may belong here; Byington et al. 1915 wrote, "a weed that dyes black"; Choctaw)

wild indigo

*Baptisia alba* (white)

false indigo; white wild indigo

*yvhv em vlikv* (*yvhv*, wolf, *em*, its, *vlike*, clan, Creek)

***Baptisia lecontei*** (named for Lewis Leconte, also sometimes listed as “Le Conte” (1782–1838), a naturalist from Liberty County, Georgia, who was a brother of Capt. John Eatton Leconte who searched for the headwaters of the St. Johns River) (= *Baptisia tinctoria* misapplied)

horsefly-weed

rattleweed

[pineland] wild indigo

At least the Cherokee, Koasati, and Ojibwa used several *Baptisia* species to make a blue dye (Hamel and Chiltoskey 1975, Moerman 1998). That information on usage as a dye was apparently transmitted to European botanists after Linnaeus described *Crotalaria alba* in 1753, which is now *B. tinctoria*. *Baptisia* was distinguished from other legumes in the eastern United States in 1808 because it was considered a substitute for *Indigofera*, the true indigo. It is now known that this North American genus contains 17 species endemic to the eastern United States (Mabberley 1997). Because the pods of *Crotalaria* and *Baptisia* are similar, and both genera are poisonous, the mistake by Linnaeus is understandable (Lampe and McCann 1985, Foster and Caras 1994). The entire *Baptisia* plant contains numerous alkaloids, but especially cytisine (Lampe and McCann 1985). Since *Baptisia* is used in modern herbal preparations in Europe, that is where most recent poisonings have taken place (Foster and Caras 1994).

Although *B. tinctoria* does not occur in Florida, a narrow endemic, *B. lecontei*, does. The two are so similar that substitution of the Florida species for the more widespread *B. tinctoria* is likely. Not only was *B. tinctoria* used for dyeing, but it was also an important component in indigenous medicines. People from the Micmac of Nova Scotia in Canada south to the Cherokees of the Carolinas used it in medicine. Infusions were made to stop vomiting, as an emetic, purgative, toothache remedy, to clean cuts and ulcers, as a douche, and to treat rheumatism, kidney trouble, cramps, sprains, and venereal diseases (Moerman 1998).

*Baptisia alba* was used by the Choctaw to treat swelling, and by the Koasati against rheumatism (Taylor 1940); thus, their neighbors the Creeks surely also applied it. Farther west, the Meskwaki of Iowa used a root mixture on wounds and sores, and to treat piles, catarrh, and snakebite (Moerman 1998). They also put it into a compound infusion for dropsy. The Osage used some species for an eyewash (La Flesche 1932).

Porcher (1863) and other physicians of the southeast at the time used the plants, considering them to act “violently as an emetic, cathartic, and subastringent antiseptic.” Porcher (1863) says that a “Dr. Thacher speaks highly of its efficacy as an external application to obstinate and painful ulcers.” That use reflects a common theme among indigenous people.

### ***Bails: Saltwort***

(From Greek *batis*, an ancient name applied to some other seacoast plant in Greece)

If you go to Everglades National Park and drive nearly to land’s end at Flamingo, there is a trail that leads southwest along the coast toward Cape Sable. They call this the “Prairie Trail.” Be sure to make the walk in the wintertime, preferably just after a really

cold night. Otherwise, the mosquitoes will remove your entire blood supply before you have walked a

***Batis maritima*.** a. Branch, b. Staminate inflorescence, c. Staminate flower bud. d. Complete staminate flower and staminate flower dissected, e. Petal. f. Floral diagram of staminate flower, g. Pistillate inflorescence, h. Complete pistillate flower and pistillate flower dissected, i. Floral diagram of pistillate flower. *Drawn by Priscilla Fawcett. From Correll and Correll 1982.*

half-mile. On a cool morning, it is usually possible to walk a couple miles and back with loss of only a few pints of blood.

Along the trail, there are large open “flats” that are covered with marl and little vegetation. These places led the first British surveyors mapping along the Florida coast to believe that they were old Indian gardens (DeBrahm [1775] 1971, Romans [1775] 1961). Yet, they also commented on the saline vegetation along that coast. Between the open areas are expanses of a southern Florida version of salt marsh, which is actually a tropical variant that barely reaches north to the United States. Dominant among these halophytic plants are glassworts (*Salicornia*), oxeeye daisies (*Borrchia*), Christmas berry (*Lycium carolinianum*), and saltwort (*Batis maritima*). If the walk occurs during the mass

migration of great southern white butterfly (*Ascia monuste*), the reward for blood loss is amply compensated. This butterfly is distinguished by its unique phosphorescent blue antennal tips, and salt-wort is its favorite food. These butterflies flock to saline shores and deposit their eggs on *Bails* to assure their next generation will have ample food. This strategy has worked well for them for untold thousands of years because there have always been flat regions on tropical shores where the saltwort and the butterflies thrive.

*Bails* came to be recognized in Europe comparatively late. It was described by Linnaeus, but not until the tenth edition of his *Systema Naturae*, published in 1759. He took the generic name from Patrick Browne who had proposed it in 1756. Both continued use of an ancient Greek word, *batis*, that Pliny (A.D. 23–79) applied to a seacoast plant in Greece. Of course, the American plants were not the same as the Greek. There are two versions of the meaning of the genus. The usual conservative approach is to say, simply, “an ancient name for a seacoast plant.” Some add that Pliny was the original source, but that the identity of the plant he called *batis* remains unknown. Without further detail, Borror (1960) wrote, “*bati*, -s...the ray fish.” Apparently, the name has been used for a plant and an animal, so that really does not help much. To confuse things further, Correll and Correll (1982) wrote that the genus was taken “from a fancied resemblance to the fruit of a blackberry.” What they did not add was that *batos* in Greek is the blackberry, and *batus* in Latin is a bramble, or blackberry. Yet, these two words, *batis* and *batos*, are not the same because Borror (1960) listed them both in distinct entries. So, let’s leave it at the vague “a name used by Pliny for some coastal plant.”

Whatever language they speak, people throughout the Americas have names for these plants. Since *B. maritima* ranges from North Carolina to Florida, Bermuda, the Bahamas, the West Indies, and from southern California to Peru and Venezuela, several languages are involved. Curiously, *Bails* also occurs in Hawaii, so there is yet another language.

In English *B. maritima* is called beachwort, pickle-weed (USA), salt plant (Virgin Islands), sea fennel (Jamaica), and turtle-weed (Bahamas), in addition to being known as saltwort. Some even call them samphire, which is an English loan-word. Originally samphire was a French common name, but it evolved into an almost unrecognizable form as English speakers mispronounced it. The first record in French seems to have been 1545, when the name *herbe de Saint Pierre* (St. Peter’s herb) appeared in Middle French, but it must be older. Even Gaelic speakers used the name *saimbhir*. In the Old World where the name originated, it was applied to both *Crithmum maritimum* (Apiaceae) and *Salicornia* (Amaranthaceae). People living in the Mediterranean and in the Caribbean heard the French name and rendered it *sampiere* or *sampere*, among other variations. Eventually, it became essentially standardized as samphire, and remains so in Jamaica and several other places. In those same places, the name “glasswort” seems to have replaced “samphire” for *Salicornia* (which see).

In Spanish-speaking areas, saltwort is known as *barilla* (Puerto Rico to Panama), *barilla de las antillas* (Antillian *barilla*), *chamís* (maybe a form of *chamiso*, usually used for *Atriplex*, Amaranthaceae, or *Chamissoa* in Amaranthaceae, Sinaloa), *lechuga de mar* (sea lettuce, Nicaragua), *planta de sal* (salt plant, Puerto Rico), *saladilla* (little salty one, Tamaulipas), *vidrillo* (little glassy one, Sinaloa), or *vidrio* (glass). Usually, the last two are applied more to *Salicornia*, but this emphasizes the confusion, or alternate classification, by people living in the range of the plants.

In French-speaking areas, the small shrubs are *crisse marine* (marine cress, Hispaniola) or *herbe-a-crabes* (crab herb, French Antilles). Cress is the English name usually given to several members of the Brassicaceae, and some of these mustard relatives grow beside *Bails*. The inhabitants of Aruba, Bonaire, and Curaçao call it wild banana, *banana di rif* [*bananireff*] (“reef banana”), or *rifbanantje* (reef banana tea). There is nothing that resembles a banana to most of us. Perhaps these people have something else in mind, as they use the same name for a *Heliconia*. Hawaiians call it *'akulikuli kai* (*'akulikuli*, succulent plant, usually applied to *Sesuvium portulacastrum*, *kai*, toward the sea).

People have good reason to have names for these plants. First, the leaves are edible; food was likely the first use. Duke (1972) has called them a “presalted salad.” *Bails* has also been used as a potherb, a puree, and a pickle. Pickled in vinegar, they are used in Cuba as an antiscorbutic (Roig 1945). Other medicinal uses include applying a plant decoction internally and externally for syphilis, skin diseases including psoriasis and ulcers, for menstrual pains, against gonorrhea, and even asthma (Morton 1981). Some consider them aperitif and diuretic. A few people consider a daily salad of the plant a remedy for constipation, but they also take it for rheumatism and gout.

Many of the older publications point out that the plants are rich in iodine and bromine. These are important micronutrients that coastal people rarely lack, but inland groups sometimes need them, particularly the iodine, to avoid goiter. The plants have also been used as a source of soda (sodium bicarbonate). Perhaps most surprising, the Seri in Sonora, Mexico, use the crushed roots to sweeten their coffee (Felger and Moser, 1985), apparently a unique usage.

One of the most important other uses was to make soap. The plants were burned, and the ashes mixed with animal fat in the old tried-and-true method. Because of the high potash (potassium carbonate) content, the resultant soap might take off as much skin as grime and dirt, but it filled a need that preceded modern commercial products. This kind of soap was often referred to as “lye soap,” and was highly alkaline.

### ***Berchemia*: Rattan Vine**

(The name honors 17th- or 18th-century Dutch or French naturalist Jacob Pierre Berthoud van Berchem)

***Berchemia scandens*.** From Britton and Brown 1897.

Perhaps the rarest woody vine in southern Florida is rattan vine, *Berchemia scandens*. However, the farther north one goes up the peninsula, the more common this temperate species becomes. The range of the genus is almost entirely within the United States, going from Virginia to Florida, and from Missouri across southeastern Oklahoma to Texas. There are herbarium specimens of the species in Chiapas and Guatemala, but little else was found about them in those regions. If they grow anywhere, they should be in Tamaulipas. So, perhaps the species is not really endemic to the United States.

There are not many common names for this species, and some of them reflect a complicated, confusing history. The dominant name for the species seems to be “rattan vine,” with vine rattany, supplejack (or Alabama supplejack), and blackjack (Louisiana) less common.

As a common name, the elements of “rattan vine” date to the 1600s. The first usage of the word “rattan” in English was in a report written by a British visitor to Sri Lanka (Ceylon) in 1681. “Rattan” is another loan-word in English. This one is not borrowed from the European languages, but from East Indies Malay. The original spelling was *ratán*, and that is based on *raut*, to trip, peel, or strip. Those words applied originally to the palm genus *Calamus*. While the “true” rattan still comes from palms, it is not confined to that genus, and may be taken from several genera. The long, flexible strips of palm stem are the items originally meant by “rattan.” People in the range of *Calamus* long ago learned to use the flexible wands for weaving a variety of items even though production is now mostly confined to chairs and lounges.

“Vine,” of course, was originally a word specifically to mean the grape vine (*Vitis vinifera*). Western cultures then broadened the word to mean any twining, climbing, or creeping life-form (Austin 1994). Indeed, in places using older versions of English, such as Sri Lanka, “vine” still refers to only the grape vine, *Vitis*.

The name “vine rattany” also has a contorted history. It seems that the second element, rattany, was derived from a South American word, apparently Quechua of the Andes. The original was *ratânia* [or *ractania*, *rataña*], and referred specifically to the genus *Krameria* (which see). The confusion between *Berchemia* and *Krameria* apparently dates from the late 1700s and early 1800s when people used more of a *Krameria* extract as medicine and to adulterate port wine. Rattany, for *Krameria*, in that context first appeared in 1808. Even sea grape (*Coccoloba uvifera*) has been called false rattany; so there were perhaps several plants involved with similar uses.

“Supplejack” is a compound word that was first applied by British physician Hans Sloane in 1725 to plants in Jamaica. He complained about the stems of the plants being so thick that they barred his progress in the countryside. In its original sense, it was restricted to plants in the Sapindaceae, including *Cardiospermum* (which see) and *Paullinia*. Later, it came to be used specifically for *Berchemia*, apparently about the time that Frederick Pursh was publishing his *Flora Americana Septentrionalis* (Flora of North America) in 1814. Pursh was the first to apply the common name to *B. scandens* in the Dismal Swamp near Suffolk, Virginia. Williams ([1837] 1962) called the vines “supple jack” and wrote “walking canes of this vine are much admired.”

Other than transcription of the generic name into other languages (e.g., *Berchemie*, German, and *berchémie*, French), there seem to be common names in only four indigenous languages. Creek said *istinokwana:ya* (*este*, person, *nokwv*, neck, *vyofetv*, to heal) and Mikasuki *cokaslakni* (*cokasî*, grapevine particularly *Vitis shuttleworthii*, *lakni*,

yellow). Koasati simply said *apihci okcakkó* (*apihci*, stem, *okcakkó*, green). Siouan speakers said *he'sanme'li* (*he'same*, vine, *me'li*, black, Tunica), and the Biloxi *to'hu sũ'pka* (*tohu'di*, rattan, *sũ'pka*, black). The Seminoles used a complex infusion of stems for chronic ailments, and in childbirth. However, even though their names are not recorded, other Muskogean people also used the plants (Taylor 1940, Speck 1941). The Choctaw used the vines for blood problems. The Houma called it *liane noire* (black vine) and used decoctions of leaves and bark for “impotency” in either males or females. Presumably, that meant being barren, although some claim that it was used by “American Indians to restore youthful vigor and sexual vitality!” (Coyote Creek 2003). A cold infusion of the burned stems was used by the Koasati as a cough medicine (Taylor 1940). Hocking (1997) indicated that the root has been used against syphilis, but gave no details. Although there seem to be no reports of chemicals in the American species, several glucosides and phenols have been found in its Japanese relative *B. racemosa* (Inoshiri et al. 1988, Inoue et al. 1990).

Other than medicines, native inhabitants of North America used the stems to fasten dugout canoes to shore and for other fastening purposes. Also, the woody stems were used to weave baskets and chair seats. At least in Mississippi the vines are also valued as important pollen sources for honey.

*Berchemia* was named in 1825 by A.P.de Candolle in his *Prodromus*, a flora of the then-known world. The genus contains perhaps 12 species (Mabberley 1997). These plants are found in southeastern Asia, Africa, Madagascar, and one single species in North America. Outside the Americas, there is evidence that at least one other species has been used; *B. discolor* in tropical and southern Africa has edible fruits utilized in Uganda. Rattan vine, however, should be treated with caution because it is considered mildly poisonous (Russel et al. 1997).

Rattan vine is associated with wetlands and disappears with habitat loss. That may be one of the reasons it is considered endangered in the State of Illinois (Illinois Natural History Survey 2003). Considering its apparent rarity, perhaps it should be considered endangered in Mesoamerica also. There are herbarium collections at Missouri Botanical Garden from Chiapas (by D.E.Breedlove in 1976) and Guatemala (by A.J.Sharp in 1945), but neither of the floras of these areas lists the genus.

### ***Betula***

(*Betula*, the Latin name for birch; akin to Hebrew *betula*, maiden bride, Hebrew *bat*, and Akkadian *bîntu*, girl, daughter)

*beith* (Gaelic)

birch (from Old English *here* or *beorc*, from Latin *betula*); cognates include *abedul* (Spanish); *betulla* (Italian); *birck* [*berk*] (Dutch); *birk* (Danish); *Birke* (German); *bjork* (Norwegian); *björk*

***Betula nigra*.** a. Tip of branch, b. Leaf.  
c. Pistillate catkin, f. Nutlet with bract.  
e. Bract. *Drawn by Vivian Frazier.*  
From Correll and Correll 1972.

(Swedish); *bouleau* (Quebec, and Europe, cf. Turner [1548] 1965)  
*mianoo's* (Potawatomi)  
*onagúchscha* (Onondaga)  
*semida* (Greek, cf. Turner [1548] 1965) *vidoeiro* (from Latin *betula*,  
through an archaic  
*vidoo* or *vido*, plus the suffix *-eiro*, tree, Portuguese)  
*wigwass* (Ojibwa); *winachk* [*wihinachk*] (Delaware); *wuskwiw* (Plains  
Cree)

***Betula nigra* (black)**

*akcelelas'kv* [*ak-cecvláskv*] (*oke*, water, *cele*, birch?, *lvste*, black,  
Muskogee)

[black, red, river, water] birch (from Old English *here* or *beorc*); sugar  
birch (Quebec, recorded by Kalm [1753–1761] 1972)

*lokapi* (Koasati); *opahaksun* (Choctaw)

*onàget* (Onondaga)

*yap koko'ha* (tree breaks brittle, Catawba)

Birch trees were important to all European cultures, having names in Latin, Greek, Hebrew, and Gaelic. It was *beith*, the white birch (*Betula alba*) that formed the first letter of the old Gaelic alphabet (Dwelly 1933). The dwarf birch, *B. nana*, was known as *beith bhog*, and formed the letter “P” in the Gaelic alphabet. Gaelic expressions included, “*Beith, luis, nuin*” the equivalent of “A, B, C” in English, as a euphemism for alphabet. The expression ‘*Sa bheith chubhraidh*’ means “in the fragrant birch,” and the Buchanan clan had the tree as their badge. Four-time winner of the Pulitzer prize for poetry Robert Frost was a newcomer to admiration of *Betula* when he published a collection of poetry including the poem “Birches” in 1915 (Frost 1992).

The Creeks used *B. nigra* to treat pulmonary tuberculosis (Swanton 1928a). The Catawbas boiled the buds for a syrup and added sulfur to make a salve to treat ringworm and sores (Speck 1937). The Alabama boiled the bark to treat sore hooves in horses (Vogel 1970). The Cherokee chewed the leaves to stop dysentery or made an infusion of them as a remedy for dysentery, colds, and urinary problems (Hamel and Chiltoskey 1975). Farther north, the Ojibwa took a decoction for stomach pains (King 1984).

The essential oil methyl salicylate in *Betula* now is produced synthetically, although it formerly was an economic item distilled in Appalachia (Foster and Duke 1990). Although it was once widely used to alleviate rheumatism, gout, scrofula, bladder infections, neuralgia, and as an anti-inflammatory and analgesic, the oil is toxic and easily absorbed through the skin. Fatalities have been reported following its use.

Wood has been used for furniture, woodenware, wagon hubs, and fuel (Vines 1977). Sugar was obtained from the sap in the spring (Hedrick 1919). People in Scotland made a fawn dye from the bark of *Betula*, and perhaps the American species also served the same purpose (Dwelly 1933).

### *Bidens*

(From Latin *bis*, twice, *dens*, tooth, because the fruit [cypsela, *sensu* Spjut 1994] has two “teeth” or barbs)

*bident* (from Latin *bidentis*, Quebec), double-tooth (a notation of the two-parted pappus resembling teeth); *Zweizahn* (two tooth, German)

*brønsle* (simple term, Norwegian)

bur[burr]-marigold (the proper name Mary, presumably alluding to the Virgin Mary, plus gold, their color; in use by about A.D. 1300, the name of several yellow-flowered Asteraceae, originally *Calendula*)

cuckold (*cuckoo*, the bird, from French *coucou*, plus with the pejorative suffix *-auld*. The word was in English about A.D. 1250 for the husband of an unfaithful wife; perhaps applied because the fruits were careless about where they attached themselves)

*fourchette* (Quebec)

harvest lice

***Bidens laevis*.** From Institute of Food and Agricultural Sciences.

Spanish-needles (first used about 1845 for *B. bipinnata*)  
sticktights

***Bidens bipinnata*** (twice-pinnate or lobed)  
cuckolds  
high-brighties (southern Appalachia)  
[soapbush, Spanish] needles

***Bidens frondosa*** (leafy, referring to the outer involucre)  
beggar's-lice (in use about 1880 for several plants with sticky fruits, including *Galium*, several Boraginaceae, and Asteraceae, Maine);  
beggars' tick(s) (Thoreau apparently wrote the word first in *Walden* in 1854); devil's beggar-ticks  
boot-jacks ("boot-jack" is a forked instrument to remove boots; in use for that tool since 1841; apparently applied here because of the similarly forked fruit, Connecticut, Pennsylvania)  
common bur-marigold  
cow lice  
cuckles [cockles] (a variant of cuckold, Massachusetts, New York)  
devil's pitchfork (Massachusetts, Vermont)  
old-ladies' clothes-pins (Massachusetts)  
rayless marigold  
stick-seed [stickseed, sticktight(s)]  
*takfun hvste* (*takfun*, an archaic name, probably specifically for *Bidens* plants, *lvste*, black, Muskogee)

***Bidens laevis*** (smooth)

smooth beggartick

wild-goldenglow

***Bidens mitis*** (ripe; the original specimens had mature fruits)*ha:sâ:bî* (sun replica, Mikasuki); *hasi aha:ka* (*hvsē*, sun, *vhaketv*, resembling, Creek)

small-fruit beggar-ticks [smallfruit beggarticks]

My students learned about a plant known locally as “Fakahatchee Gold” soon after we began working on the vegetation of Fakahatchee Strand State Preserve in Collier County (Austin et al. 1986, 1990a,b). The plant name sounded like one for marijuana (*Cannabis*), but actually consisted of the dried leaves of *Bidens alba* used as a tobacco substitute. A smoker among them said they were not too bad in a pinch.

While Linnaeus created *Bidens* as a genus, it had been used before him by J.P.de Tournefort in his *Institutiones rei herbariae* (Institution of the King’s Herbarium) of 1700. Linnaeus knew 11 species in 1753; there are now about 200 (Mabberley 1997). Several of these are widespread, but *B. alba* is pantropical. There are between 40 and 50 native species within the United States (Kartesz 1994).

*Bidens bipinnata* was used by the Cherokee to treat intestinal worms and the leaves were chewed to relieve sore throat (Hamel and Chiltoskey 1975). Hocking (1997) recorded that *B. frondosa* has been used as an emmenagogue, but does not state if by indigenous people or settlers. Paiute in the Great Basin used *B. laevis* for food, presumably the leaves cooked as greens (Moerman 1998).

The only record found within Florida is among the Seminoles. Both Sturtevant (1955) and Moerman (1998) recorded the plants as *B. coronata*, but Wunderlin (1998) says that plant is not in the state. Apparently, the plants used were *B. mitis*. Seminoles used an infusion for “Sun Sickness” (eye disease, headache, high fever, diarrhea), “Fire Sickness” (fever, body aches), and “Mist Sickness” (eye problems, fever, chills).

The only species that made it into most books is *B. bipinnata*. That species was discussed by several Europeans before being named by Linnaeus in 1753. Robert Morrison knew the plants by 1680 from cultivation in London; Paul Hermann had cultivated the herbs by 1687 in Leiden; and Leonard Plukenet had it by the 1690s. Linnaeus’s former student Peter Kalm ([1753–1761] 1972) complained about their seeds sticking to his clothing in Pennsylvania in 1748.

In 1955, the U.S. Dispensatory reported, “The roots and seeds were popularly used as emmenagogues, and by the eclectics in laryngeal and bronchial diseases.” Hocking (1997) added that the plants are used, apparently in Argentina, as ear drops, to treat conjunctivitis, and as a hemostyptic. Foster and Duke (1990) warn that the chemicals in this plant may be irritant. Duke et al. (2001) discuss only *B. pilosa* and *B. tripartita*; neither is native to Florida.

Long after my students tried “Fakahatchee Gold,” I learned from my biochemist friend Kelsey Downum at Florida International University that *B. alba* contained so many potent compounds that he had never seen insects eating the leaves. After a little searching, I found that only the dainty sulphur butterfly (*Nathalis iole*) ate the leaves. Hsu (1986) and Foster and Duke (1990) say that *B. pilosa*, often confused with *B. alba*, has

phytosterin B, a compound that acts as a central nervous system depressant and lowers blood-sugar level. No wonder a single butterfly can eat the leaves.

***Bignonia***

(With this name, Linnaeus honored Abbé Jean-Paul Bignon, 1662–1743, court librarian to King Louis XIV in Paris)

***Bignonia capreolata*.** From Britton and Brown 1898.

***Bignonia capreolata* (twining)**

*batafó:li* (Koasati)

*chukfi imaseta* (*chuki*, rabbit, *in*, its, *aseta*, string, Choctaw)

crossvine (alluding to the cross that is formed by the vascular bundle in a cross section of small stem)

quarternvine

*Trompetenblume* (trumpet flower, German)

The first person to send crossvine to Europe has not been found, but it was possibly John Tradescant the Younger. He collected plants first on the James River of Virginia in 1637, and made other voyages as late as 1654. The vine appeared as an illustration published in 1674 by Italian botanist Paolo Boccone (1633–1703). Later, Linnaeus studied the climbers at the *Hortus Cliffortianus*.

Creeks used the plant as medicine, probably as did their neighbors (Swanton 1928a). The Choctaw made a decoction of the mashed bark to treat dropsy (Taylor 1940); the Houma made a root infusion to gargle for diphtheria (Speck 1941); and the Koasati used a decoction of the bark as a bath and drank it to relieve headaches and rheumatism (Taylor 1940). In the Carolinas, the Cherokee used an infusion of the leaves to purify the blood (Hamel and Chiltoskey 1975). Byington et al. (1915) said Choctaw used *chukfi*

*imaseta* to treat dysentery, and simply that it was “the vine which grows and adheres to the bark of trees, having a trumpet-shaped blossom.” Perhaps they meant *Campsis*, but *Bignonia* is more likely. Porcher (1863) records that, among South Carolina tribes, “a strong decoction of the bark cured cases of putrid sore throat. It is useful also in pleurisy.”

### ***Blechnum***

(Pliny, A.D. 23–79, modified the Greek name *blechnon* into Latin *blechnum* for the male fern *Aspidium felixmas*; Linnaeus reapplied it to these relatives)

#### ***Blechnum occidentale*** (western)

*Abendlaendischer Rippenfarm* (western saw-fern, German)

*doradillo* (golden one)

hammock fern

*helecho* (fern); *helecho de ladera* (slope fern, Veracruz)

New World midsorus fern (a book name, Wherry 1964)

*palma boba* (crazy palm)

***Blechnum serrulatum*.** a. Fertile plant, b. Tip of fertile pinna. c. Central portion of pinna to show sporangia, d. Sporangium. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

*paso de negro* (black walk, Cuba)  
*uap-hia*

***Blechnum serrulatum* (toothed)**

*asa-jike* (Arawak, Suriname)

*blechne* (French)

*Rippenfarn* (saw fern, German); saw fern  
 swamp fern (Florida)

*tapenykafa'bi* (*tapeny*, fern, *kafa'bi*, maybe a mistranscription of *cyfahe*, lacking pattern or *kvfake*, scrambled, Creek); *tapintkafā:bī* (*tapinti*, fern, Mikasuki)

toothed midsorus fern (a book name, Wherry 1964)

Linnaeus ([1753] 1957) named both *Blechnum orientale* and *B. occidentale*. Unfortunately, he mixed them up and called them by reverse names. He listed *B. orientale* as occurring in middle America, and *B. occidentale* as occurring in China. That only caused problems for a short while because he corrected his mistake in 1763.

Linnaeus named *B. occidentale* based on *Lonchitis justa nervum pulverulenta* (*Lonchitis* with dusty veins) of James Petivier's illustration, published in 1712. All Linnaeus said of origin was "in *America meridionale*," but James Petiver (ca. 1663–1718) knew the plants from Jamaica and that is the basis of the Linnaean name. There are now between 150 and 200 species around the world included in *Blechnum*, with most of them in the Southern Hemisphere (Mabberley 1997).

In Florida, *B. occidentale* is the hammock fern or sinkhole fern. This species has a range similar to *B. serrulatum*, being known from southern Louisiana, in a few places in northern Florida (where it is endangered), the West Indies, and south to Mexico and Argentina. To date, the species has been located once in Collier County. As with most ferns, there is little in the literature about uses. Vásquez and Jácome (1997) recorded its use in treating bronchitis and coughs in Veracruz. Morton (1981) found uses only among the indigenous people of northwestern Venezuela and in Argentina. In Venezuela, the plant is used in medicinal baths and as a cure-all. People in Argentina treat nervous hysteria, constipation, bladder stones, and kidney problems with *B. occidentale*.

That paucity of information on human application of *B. occidentale* contrasts with the Asian *B. orientale* (de Winter and Amoroso 2003). In the Philippines and Papua New Guinea it is eaten. Flour is made from the rhizomes in Irian Jaya, Indonesia, and Australia. Plants are eaten after proper processing, because it also is used to induce sterility in women in Papua New Guinea. The liquid extracts from the rhizomes are also believed to stimulate the uterus. In the Philippines, plants are considered a diaphoretic, an aperitive, and are applied to cure boils and swellings. Elsewhere they are used to treat worms and bladder problems.

Given its abundance in modern Florida, it seems curious that recognition of *B. serrulatum* was comparatively late in Europe. Any wetland, particularly swamps and marshes, sometimes has almost monocultures of these ferns extending for hundreds of yards. Particularly in areas with seasonal fluctuations, little else can be found. Still, *B. serrulatum* was not described until 1792, when Louis Claude Richard (1754–1821) named it based on plants from French Guiana.

One of the most famous members of the genus is *B. indicum*, originally described in 1768 from India by Nicolaas Laurens Burmann (1734–1793). Formerly, the rhizome of that species was traditional foodstuff in northern and northeastern Australia. This species has been confused with *B. serrulatum*, and the uses of both are intermingled in the literature. As an example, Ayensu (1981) attributed medicinal uses to *B. indicum* in the West Indies, when those plants are properly *B. serrulatum*. Indeed, *B. serrulatum* grows from Florida, through the Bahamas, Cuba, Hispaniola, Puerto Rico, Mexico (Tabasco), Belize, Costa Rica, Guatemala, Honduras, Nicaragua, Bolivia, Paraguay, Peru, Ecuador, Venezuela, to southern Brazil.

Swamp fern has been used to treat wounds in the West Indies (Ayensu 1981). This usage is similar to that of many other species in the genus. However, the common names of the fern do not reveal any such uses. The only indigenous American name found for the species is *tapintkafa:bi* (*tapinti*, fern, Mikasuki), rendered *tapenykafa'bi* in Creek (Sterling in Sturtevant 1955).

The plants also are known as saw fern in English, one of the oldest names for them. That reference to the toothed pinnule margin is reflected in German *Rippenfarn* (saw fern), although the French *blechne* is a transcription of the old Greek name for the related plants. Swamp fern and saw fern both seem to have been created by people outside the academic realm, and they convey ecological and morphologically useful information. There are also some “invented” common names that seem to date from Edgar Wherry’s (1964) treatment. He called them “toothed midsorus fern,” certainly nothing that a non-academician would understand.

Although there is a paucity of information on the use of *B. serrulatum*, there is more documentation for other species. Some species have long histories of usage (Pizarro 1959). Three other tropical American species are used: *B. chilense*, called *palmilla* (little palm, Chile), is applied to wounds in the umbilical cord; *B. fraxineum* (tropical America) is given in an infusion as a cure-all; and *B. hastatum* (*palmilla*, Chile) is considered an emmenagogue and abortifacient, whose roots are anthelmintic.

From northern California to British Columbia, *B. spicant* (deer fern) is used as medicine, food, and fiber (Moerman 1998). The Hesquiat (British Columbia) chewed leaflets as a treatment for internal cancer. They also used the fronds in medicine for skin sores, and said they learned the practice from watching deer that rub their broken antler stumps on the plant. The Kwakiutl (northern Vancouver Island and southern British Columbia) took a decoction of root, a compound mixture, or held the decoction in the mouth to treat diarrhea. The Makah (Olympic Peninsula, Washington) chewed green leaves to relieve stomach distress and lung trouble. The Quinault (Olympic Peninsula, Washington) chewed leaves for colic. The Haisla (British Columbia), Hanaksiala (British Columbia), and the Nitinaht (Vancouver Island, British Columbia) peeled young stalks and ate the center portion as famine food. The Makah (northwest tip of Olympic Peninsula) used fronds to add flavor by placing them under items to be cooked. The Nitinaht and Quinault (both Vancouver Island, British Columbia) placed fronds above and below food being steamed, particularly camash roots (*Camassia quamash*). The Yurok (northern California) used the leaves for bedding.

*Blechnum occidentale* contains flavonoid glycosides and four lignans (de Winter and Amoroso 2003). Water extracts from that species showed activity against *Bacillus subtilis*, *Candida utilis*, *Escherichia coli*, *Micrococcus luteus*, *Pseudomonas aeruginosa*,

and *Staphylococcus aureus*. The rhizomes are considered antiviral, and they have strong inhibitory effects on influenza virus.

There are several known chemicals in different species of *Blechnum* that may be active in some of the remedies. Most common among the species are tannins and essential oils. However, a number of other compounds have been found in different species, including flavonoids, glycosides, and ecdysones (deoxycrustecdysone, deoxyecdysone, and alpha-ecdysone) (Chong et al. 1970, Jizba and Herout 1974, Miraglia and Padua 1985, Mesquita and Gottlieb 1985, Suksamrarn et al. 1986, Yusuf 1994).

### ***Bletia*: Pine Pink**

(Named by Hipólito Ruiz López, 1754–1815, and José Antonio Pavón, 1754–1844, in honor of the Spanish botanist Luis Blet, an apothecary and owner of a botanical garden in Algeciras, Spain; this pharmacist accompanied Ruiz and Pavón on their expedition to the New World in the late 1700s, and they “thanked” him by creating this genus bearing his name)

***Bletia purpurea*** (purple, the flower)  
 pine pink (Florida)  
*yie le* (Zapotec, Oaxaca)

In spite of its common name in English, the pine pink is not a “pink,” i.e., a member of the Caryophyllaceae. Instead, it is a pink-purple orchid that grows in pinelands and upland regions near hammocks and swamps. In Florida the plants are restricted to the southernmost counties (Broward, Collier, Lee, Miami-Dade, Monroe, including the Keys, and Palm Beach), and the species is listed by the state as threatened with extinction (Coile 2000). The species is also listed as endangered in Colombia. Throughout its range, this endangerment has been brought about by drainage, changes in fire frequency, and increased human intervention in habitats. Essentially, people are now occupying the space that formerly was used by the plants. As Luer (1972) found recorded in the early

***Bletia purpurea*.** a. Flowering plant, b. Flower, front view spread open. c. Lip and column, side view. d. Lip, spread out. e. Fruiting inflorescence. Drawn by Gordon W.Dillon. From Correll and Correll 1982.

1970s, “mile after mile of virgin pineland is succumbing to the advancing tomato patches” in Miami-Dade County. Not only pineland, but other habitats also continue being developed in many parts of southern Florida, although some areas have been set aside as preserves. For example, these terrestrial orchids are still reasonably common in the Corkscrew Swamp, Fakahatchee Strand State Preserve, Big Cypress National Preserve, and Everglades National Park.

John K.Small (1933) was one of the first people to study the pine pink in Florida, and he noted it as “An epiphyte form growing on the bases of cypress trunks, stumps and ‘knees’ in the Big Cypress Swamp...has apparently cleistogamous flowers with the lip nearly similar to the two lateral petals.” Luer (1972) confirmed Small’s observations on the orchid and noted, “The flowers of some plants do not open completely; those of others, not at all.” Because this orchid is on the northern fringe of its range in southern Florida, it has “outrun” its pollinating bees. In Colombia those are Euglossine bees, with *Euglossa hemichlora* the primary visitor. Even though swallowtail butterflies (*Papilio* sp.) pollinate the orchids in Colombia, there is no evidence of them doing so in Florida.

There may have been more than mere appreciation for Blet's aid being shown by Ruiz and Pavón when they named the orchid after him. Luer (1972) noted: "Perhaps he [Blet] used the pseudobulbs in concocting potions, a practice still carried out by native people." It may have been Blet who brought to the Old World the first information on these medicinal orchids. Now that the plants are so rare, most of that knowledge seems to have been lost along with the plants. One of the few other places where medicinal use is recorded for this terrestrial orchid is Roig (1945) who wrote that a handful of the whole plant was put in a bottle of boiling water, and "then used as an effective stomachic." In several places in the West Indies, an infusion of the boiled bulbs was used to treat poisoning by ciguatera in fish. The split bulbs were considered good for treating wounds (Uphof 1968). Dried bulbs are not only used as the basis of a tonic, surely the application mentioned by Roig, but also as glue in Sonora, Mexico (Martin et al. 1998).

This medicinal use is so old that the plants have also acquired something of a mystical association in the Catholic Church in the American tropics. The orchids resemble candlesticks, and this similarity led to their Spanish common name. They are *candelaria* (candlestick), and have been incorporated into the Feast of Purification on February 2, also known as Candlemas Day. This old Jewish religious tradition dates from long before the Bible, and it is recorded in Luke 2:22–39. The celebration originated with the Jewish tradition of women being required to go into seclusion for 40 days after giving birth. According to custom, Mary and Joseph brought the baby Jesus to the temple on February 2, at the end of her seclusion, to "redeem" their son as a first-born male with an offering, probably of two turtledoves. The story goes that they were greeted by the aged Simeon who burst into song on first seeing the infant. His song, called *Nunc Dimittis*, has a long and prominent role in Christian worship. Because of a phrase in Zephaniah 1:12 that reads "I will search Jerusalem with candles" this day is also known as Candlemas, and sometimes observed with a candle-lit procession.

### *Blutaparon*

(Perhaps derived from Latin *blitum*, historically meaning *Amaranthus*, and Greek *paron*, *para*, beside or near; Rafinesque may have been noting that the genus was near or related to *Amaranthus*)

***Blutaparon vermiculare*.** a. Branch with inflorescence, b. Flower head. c. Complete flower (above) and flower longitudinally dissected (below), d. Flower with perianth removed, e. Floral diagram, f. Fruit, g. Seed. Drawn by Priscilla Fawcett. Correll and Correll 1982.

***Blutaparon vermiculare*** (resembling worms)

*amaranthe bord de mer* (amaranth at the sea edge, French Antilles)

beach carpet

*bledo carbonero* (charcoal saltwort)

*hierba de sal* (salt herb, Panama)

*k'uk'uk* [*kuk'uk*] (young part of a plant, Maya, Yucatan)

*perejil de costa* (coastal parsley)

samphire (applied to several medicinal and edible herbs; see also *Batis*, which is one of the other plants called this)

silverhead (of unknown origin, but it apparently refers to some morphological trait; applied by Wunderlin 1998)

The problematic biologist Rafinesque published a book in 1838 called the *New Flora and Botany of North America*. In the fourth volume of that work, he proposed the generic name *Blutaparon*. As with most of his erratic publications, the scientific establishment ignored this generic name until the 1980s. Then, James A. Mears resurrected *Blutaparon* and separated it from *Philoxerus*, into which it had previously been submerged. As now understood, *Philoxerus* is an Australasian genus that was originally described from Australia by Robert Brown in 1810 (Mears 1982a,b, Kanis 1984). As now circumscribed, *Blutaparon* contains four species in the Ryukyu Islands, the Americas, and West Africa.

One species is endemic to the Galapagos Islands (*B. rigidum*) and another to the far Asian orient, particularly the Ryukyu Islands (*B. wrightii*). The only species in the Americas is *B. vermiculare*. The species grows from the coasts of Florida and Texas, to Mexico and Central America, the Antilles, and south to Ecuador and Brazil. It also grows in west tropical Africa, and the Macronesian islands.

These plants are also like *Amaranthus* in that the stems and foliage are edible. *Blutaparon* too provides an already salted potherb or greens for meals. Some of their common names indicate that people know that trait and make use of it.

No chemical studies have been found of *B. vermiculare*. However, there have been investigations of related species. *Blutaparon portulacoides* contains an acyl steryl glycoside, flavonol (3,5,3'-trihydroxy-4'-methoxy-6,7-methylenedioxyflavone), glycosylated methylene bisflavonoid, isoflavone irisone B, and the steroids stigmasterol, sitosterol, and campesterol (Ferreira and Davis 2000, Salvador et al. 2000, De Oliveira et al. 2003). Some of these compounds have been found to inhibit *Trypanosoma cruzi*, *Leishmania amazonensis*, and Gram-positive and Gram-negative bacteria, along with the yeasts *Candida albicans* and *C. tropicalis* (Salvador et al. 2000).

### ***Boehmeria***

(N.J.B.von Jacquin, 1727–1817, named the genus to commemorate Georg Rudolph Boehmer, 1732–1803, a professor at Wittenberg)

***Boehmeria cylindrica*** (cylindric, probably an allusion to the stems)

bog-hemp

[small-spiked] false nettle

*mora de piedras* (rock blackberry, Cuba)

Linnaeus ([1753] 1957) called this herb *Urtica cylindrica*. He based the name on information from Jamaica by Hans Sloane, and from Virginia by Gronovius. All three thought it an *Urtica*. It was not until Olaf Swartz studied the Caribbean plants that he put the species in *Boehmeria* in 1788. There are now about 80 species in *Boehmeria*, mostly in the lower latitudes (Mabberley 1997). The most famous of them is *B. nivea*, a commercial fiber plant usually known as “ramie.”

*Boehmeria cylindrica* is found from Florida to Maine, southern Quebec, southern Ontario, west to Minnesota and Texas (Fernald 1950). It also occurs in

***Boehmeria cylindrica*.** a. Top of plant, b. Staminate buds and cluster of pistillate flowers, c and e. Clusters of pistillate flowers in different stages, d. Staminate flower, f. Fruit. *Drawn by Vivian Frazier. From Correll and Correll 1972.*

Bermuda, Cuba, Puerto Rico, Jamaica, Trinidad, and tropical America (Leon and Alain 1946–1953, Adams 1972, Liogier and Martorell 1982).

Moerman (1998) did not include this species, but there are archaeological and historical data that it was important to indigenous people. Whitford (1941) had material from Bushwick Cave in Arkansas, and said that the plant was used for fiber “by practically all the tribes” covered in his survey; he gave examples from only five. The Cherokee used it to make a string for a feather charm. The Delaware used the fiber in stringing wampum, and there were two wampum belts from the Iroquois using cord from *Boehmeria*. The Ojibwa made a bowstring of it. The Micmac fastened the handle of a knife to the blade with cords of the fiber and used the plant to make a cord on one of their fish spears. In his later paper, Whitford (1943) thought that this genus was used less often than either *Laportea* or *Urtica* for fibers. Still, all were “much prized for fine work.”

Given the absence of records of indigenous use, the chemical studies on the species are unusual. Beginning in the 1960s, research found chemicals in the herbs that show potential antiviral activity (Farnsworth et al. 1969, Krmpotic et al. 1972). Apparently, no work has been done on that possibility since Al-Shamma et al. (1982).

***Borrichia*: Sea Oxeye**

(Named for Danish botanist Ole Borch, Latinized as Olaus Borrichius, 1628–1690)

Among the most colorful plants in the tropical salt marshes in southern Florida are the sea oxeyes (*Borrichia arborescens* and *B. frutescens*). These two species often grow intermixed along with saltwort (*Batis maritima*), glasswort (*Salicornia*), and Christmas berry (*Lycium carolinianum*). The polychrome green of these plants is often highlighted by the varied colors of *Borrichia* leaves (gray in *B. frutescens*), red fruits of Christmas berry, and red stems of glasswort, making the salt marsh a more colorful place than one might expect. When the great southern white butterflies (*Ascia monuste*) are migrating in mass and drinking nectar on the flowers of sea oxeye, it becomes a lively and colorful spectacle.

Many botanical keys have technical, and difficult to see, ways of telling these two species apart. Yet, there are comparatively easy ways to separate them. First, the pubescence of the leaves usually works—*B. arborescens* has green leaves (in the Florida Keys exclusively so, but plants with gray, green, and mixed gray and green leaves occur in the West Indies), and *B. frutescens* is gray with pubescence. If there are still doubts, simply pinch the base of the flowers. If your fingertips come away with small punctures, then the plant is *B. frutescens*—the involucral bracts are spine tipped. Perhaps that is a painful way to separate species, but it works better than the technical traits in some publications. Probably the people who use them as medicines do not distinguish them anyhow because their common names are not distinctive. Both are compared with either an “ox-eye” or a “daisy,” or both as “sea oxeye daisy.”

“Ox-eye” seems straightforward, and it is—people were reminded of the large eyes of that work animal. What is surprising is that so many things have been compared to ox eyes. Maybe because most of us have never even seen an ox up close, we think it odd that so many comparisons should have been made. Perhaps more surprising is that the name is not really applicable to species of *Borrichia* because the centers of the flowering heads are not dark, but yellow like the rays. This error is likely a result of the history of the naming of the species and its original grouping with a European genus. My friend and colleague John Semple suggests that the alternative would be to assume that some plants are named for extremely jaundiced oxen with yellow eyes. Well, maybe...

The first comparison made in medical literature was published ca. 1400, where the plants were referred to as *Butathalmon vel butalmos, oculis bovis* (ox-eyes, spelled three different ways). In 1551, William Turner’s herbal said, “Buphthalmus or oxeye...hath leaves lyke

***Borrichia*.** *Borrichia arborescens* . a. Flowering branch, b. Flower head, side view. c. Ray flower on left, side view. d. Floral diagram of ray flower, e. Disk flower on left, side view; longitudinally dissected on right, f. Floral diagram of disk flower. g. Achene. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

*Borrichia frutescens* , a and b. Top of two different plants showing leaf variation, c. Phyllary. d. Disk corolla, e. Anthers, f. Achene. Drawn by Vivian Frazier. From Correll and Correll 1972.

fenel and a yellowe floure greater than Camomil, lyke unto an eye, wherupon it hath the name.” Therefore, the original “ox-eye” plant was the Old World genus *Bupthalthmon* (*bos*, ox, *phthalm*, eye), the cultivated ox-eye. Indeed, when Linnaeus named the New World plants in 1759, he called them *Bupthalthmum frutescens*. Apparently, no one recognized *Borrichia arborescens* until they were named by Alphonse de Candolle in 1836. At the same time, he also moved Linnaeus’s *Bupthalthmum frutescens* into the genus Michel Adanson called *Borrichia*.

After the 1450s, many things were named for ox-eyes. Among them are sore eyes in humans, at least nine bird species, what we recognize now as seven genera of Asteraceae, two genera of fish, a drinking cup, a small glass model of an eye, and a small concave

mirror. By 1866, two West Indian composites had been called ox-eyes—the creeping ox-eye or West Indian marigold (*Wedelia*), and the seaside ox-eye (*Borrichia*).

The name “daisy” is a similarly complicated story, but it is much older. “Daisy” seems to have been applied to European plants about A.D. 1000 in a list of medical plants. Part of the list consisted of “gearwe, fifleafe, daezesege, and synnfuelle.” By Chaucer’s time, ca. 1385, daisy was more recognizable as “daysyes.” This is what we now call *Bellis perennis*. This species was a favorite of poets and others and figures prominently in the literature following Chaucer, including notables like Spenser and Shakespeare. “Daisy” has subsequently been applied to at least ten genera of composites, a sea-anemone, a term of endearment, a slang expression for something considered first-rate, and a number of other things.

*Borrichia frutescens* has comparatively few common names, and they all overlap with those applied to *B. arborescens*—ox-eye daisy, sea ox-eye daisy, and sea ox-eye. These are applied to both throughout English-speaking regions. In the Bahamas, they add to this seabush and samphire (see discussion of saltwort, *Batis*).

Otherwise, the plants are compared to a number of others, including bay candlewood (allusion to *Amyris balsamifera*, Caymans), bay marigold (a comparison with *Tagetes*), *clavelón de playa* (beach carnation, Puerto Rico), *romero* (rosemary, Cuba), *romero de costa* (coastal rosemary, Cuba), *salvia marina* (marine sage, Cuba), *té marino* (marine tea, Hispaniola), *té de playa* (beach tea, Hispaniola), and *verdolaga del mar* (sea purslane, Puerto Rico). All the plants compared are similarly medicinal or otherwise useful. Many of these same names are used for some *Croton* (Euphorbiaceae) species that have similar uses.

The uses include boiling the leafy branches and taking the decoction for colds and coughs. This “tea” is also used against whooping cough, back pain, and colds (Morton 1981). Juice from the leaves is given to babies with colds and coughs in the Bahamas. Decoctions are also taken for chest complaints, asthma, and malaria in Cuba (Roig 1945). Most surprisingly, an infusion of leaves is widely considered an antidote for eating poisoned fish (ciguatera) in Barbuda (Von Reis 1973).

Properties listed for the plants include being antiscorbutic and stimulant. Maybe it is the bitter taste that is stimulant, because the leaves have a balsam-like bitter flavor, and are eaten with vinegar in salads (Roig 1945).

A third species of *Borrichia* was described in 1920 by Britton and Blake from a Cuban collection. Semple (1977, 1978) demonstrated that this was really just the hybrid between *B. arborescens* and *B. frutescens*; it is intermediate in leaf color between the two parents and has soft spines on the heads. This hybrid, *B. ×cubana* can be found at many locations in the Florida Keys from Miami to Key West in places where both parents grow.

### ***Botrychium***

(From diminutive of Greek *botrys*, a cluster of grapes, because of the appearance of the fertile fronds)

moonwort (translation of Medieval Latin *lunaria*, for the European fern formerly called *Lunaria minor*, now *Botrychium lunaria*; first used in

English in Lyte's 1578 translation of Dodoens's herbal, with "The herbe is now called in Latine *Lunaria*...in English Lunarie or Moonewort"); cognates are *maankruid* (moon herb, Dutch); *Mondkraut* (moon herb, German)

***Botrychium virginicum*** (of Virginia)

*botryche de Virginie* (Virginia botrychium, Quebec)

[common, Virginia] grape fern

*hoeta hocksish* (*hoeta*, vomit, *hocksish*, to plant, Chickasaw)

pubic weed

rattlesnake fern

*Botrychium* is a genus of ~50 species spread in a circumpolar distribution, and disjunct to tropical mountains (Mabberley 1997). There are records of *B. virginicum* being used among the Abnaki, Cherokee, Chickasaw, Iroquois, Ojibwa, and Potawatomi (Smith 1933, Moerman 1998).

The Abnaki used the plants as a demulcent and gave it to sick children. The Cherokee made a decoction of the roots and gave it as an emetic; they also rubbed the liquid on snakebites (Hamel and Chiltowsky 1975). The Chickasaw used the fern as an emetic as did the Cherokee, but also considered it diaphoretic and expectorant (Campbell 1951). The Iroquois treated coughs with the plant, especially those associated with tuberculosis. The Ojibwa considered the fresh root a cure for snakebite, but also thought it was repellent to the ophidians (Densmore 1928). They made a poultice they applied to cuts and used the fern to treat tuberculosis. The Potawatomi also used it medicinally (Smith 1933).

***Bourreria*: Strong Back**

(Named for J.A.Beurer, a Nuremberg apothecary)

***Bourreria succulenta*.** a. Flowering branch, b. Flower bud. c and d. Leaf outlines to show some variation, e. Flower, side view. f. Flower longitudinally dissected, g. Floral diagram, h. Fruiting and flowering branch, i. Fruit. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982.

From the time I arrived in Florida in 1970 and began working at Fairchild Tropical Garden, I heard about the “strongback” of the Bahamas. Nothing was ever overtly said about it, but the innuendo spoke loud and clear—the name had sexual overtones. Somewhere along the line I learned, probably from a student, that it allowed one to make love longer, with a good, strong back. Yet, nothing of that has appeared in the books, at least the floras of Florida or the Bahamas. Helen Correll, coauthor of the most recent flora of the Bahamas, would not allow Don to include common names that were vulgar. Having known Don’s earthy sense of humor, I cannot help wondering what he left out.

Botanically, strong back [strongback] is *Bourreria succulenta*, usually kept separate from *B. ovata* in the older literature. The species was named by Nicolaus Jacquin in 1760, and placed in a genus created by Patrick Browne earlier. There are at least three spellings of the generic name, perhaps because of its derivation as a patronym. However, the spelling used here is retained because of international agreement. This species ranges from southern Florida, the Bahamas, the Greater Antilles, and the Lesser Antilles south to

Trinidad, then along the coastal parts of South America in northern Venezuela and the Dutch Antilles to Panama.

One of the most common remedies made from these shrubs is used to cure thrush and other oral inflammations (Roig 1945). This usage is reflected in the common name *curaboca* (cures the mouth, Cuba). In the Dutch Antilles, a leaf decoction or an infusion of the leaves in rum is considered an aphrodisiac, "for more energy," verifying my student's earlier interpretation about the Bahamas. This usage and the others for "weak back" are indicated in names such as strongbark (Bahamas), *doncella* (little lady, Puerto Rico), *Madame Jeanne* (Haiti), *palo bobo* (crazy tree, Dominican Republic), hall bark (Bahamas), and maybe *cateicito* (little tester?, Cuba) and *goeana* (good Ann?, Dutch Antilles).

Fruits are eaten throughout the range of this and other species in the genus. This observation was noted in names including *acomat côtelette* (coastal acomat, *Homalium racemosum*, Flacourtiaceae, Guadeloupe), *ateje de costa* (coastal ateje, *Cordia collococca*, Cuba), *bois caprit bâtard* (false [bastard] goatwood, probably because of similarity of fruits to *Aegiphila martinicensis*, Guadeloupe), *bon-bon rouge* (red candy, French Antilles), *café marron* (wild coffee, Haiti), *cerecillo* (little waxy one, Puerto Rico), *mapou gris* (gray mapou, *Ceiba pentandra*, Haiti), *cotlette* (variant of *côtelette*?, Dominica), pigeon wood (Virgin Islands), and pigeon-berry (Puerto Rico). Flowers are used for nectar by honeybees, and the wood is burned as fuel. Application as fuel or other uses of the wood is probably implied in chinkwood (Antigua), and its probable variant, white-chank (Dutch Antilles), *roble [de] guayo* (*guayo* oak, Cuba, Puerto Rico), *roble negro* (black oak, Cuba), and spoon tree (English Antilles). "Cutlass" (Grenadines) may be related as a cutting instrument needed to harvest the wood. The Caribs use the stems for torches (Hodge and Taylor 1957).

A broad array of other plants are mixed with *B. succulenta* in the Bahamas to treat various maladies (Ayensu 1981). For example, leafy twigs are boiled with five-finger (*Tabebuia heterophylla*) or fiddlewood (*Citharexylum fruticosum*) to treat pain in the back or waist. The plant is also used to quiet the nerves, and to strengthen "weak-backed" children. Here a weak back may refer to kidney problems. A young plant is boiled with goatweed (*Capraria biflora*) and ram-goat dash-along (*Turnera ulmifolia*) to treat diarrhea. Fever, headache, and stiffness of the limbs are treated by boiling a branch with *lignum vitae* (*Guaiacum sanctum*); that mixture also is used in bush baths to treat the same maladies. A decoction of three-finger (*Thouinia discolor*) and fiddlewood (*Citharexylum fruticosum*) is applied externally to treat running sores in infants. Steeped inner bark with mahogany (*Swietenia mahagoni*) and gumbo limbo (*Bursera simaruba*) is used to treat low blood pressure. The Caribs in Dominica use the plant alone by taking the emollient fluid from the inner bark, which is used to soothe inflamed eyes (Hodge and Taylor 1957).

Since it is compared to *Exostema* in the common name *frutica de carey* (shrub carey, *Exostema*, Cuba), it may be because of the antiseptic use of both. Probably, the names *palo de vaca* (cow tree, Puerto Rico, Haiti), *raspa lengua* (rough-tongue, Cuba), and *raspa lengua de costa* (coastal rough-tongue, Cuba), are allied because of a bad taste. No translations have been found for *taiwai* [*taway*, *tauai*] (from *iauái*, Carib, Dominica), and *watakeeri* [*watakeeri*, *watakeli*] (probably Carib and related to "wai" in *taiwai*, Aruba, Bonaire, Curaçao).

***Bursera*: Gumbo Limbo**

(From Latin *bursa*, sacks, of aromatic oils within the plant tissues or for the German physician Joaquim Burser, or both)

Linnaeus first named the species in 1753, but he called it *Pistacia simaruba*, thinking it was related to the pistachio nut-producing genus. He had seen the specimen from Jamaica and a plate published in 1705–1725 by British physician Hans Sloane. Linnaeus also had seen the text and plate by Mark Catesby published in 1731–1732. In the interval between these two early works and his *Species Plantarum* of 1753,

***Bursera simaruba*. Drawn by  
P.N.Honychurch.**

Linnaeus had discussed the plant in his book, *Materia Medica*, published in 1749. There he simply used the name *Simaruba*.

At the time the distinction between plants called *simaruba* (or *simarouba*, a Carib word) was not clear. Linnaeus did not know those trees now called *Simarouba* because that genus was not named until 1775 by Jean Fuseé Aublet. Still, plant material called *simaruba* had been known in Europe since about 1713, when it was brought back to Europe as medicinal bark from French Guiana. Some time between his *Materia Medica* and the *Species Plantarum* of 1753, Linnaeus decided that the specimen collected by Sloane in Jamaica and the one illustrated by Catesby must be an American relative of the European pistachio. So, he listed it along with the real pistachio (*Pistacia vera*), the mastic (*P. lentiscus*, which flavors the Greek wine *ouzo*), and some others.

By 1762, Linnaeus realized he had made a mistake in 1753, and adopted a name proposed but not published by Jacquin, when he created the genus *Bursera* in the second edition of *Species Plantarum* (1762). There are two stories about how this name originated. One has it that Jacquin noticed that there were *bursa* (sacks) of aromatic oils within the tissues of the plants and thus created *Bursera*. However, it is more likely that he and Linnaeus had in mind the German physician Joaquim Burser (Latinized Joachim Burserus, 1583–1639), professor of botany and medicine in Denmark from 1625–1639,

traveler, plant collector, and friend of Gaspar Bauhin. Linnaeus also created a new name for the species he had named in 1753, and now called it *B. gummifera*. By modern international agreement, that is not permitted, but it remained until 1890 for Charles Sprague Sargent to transfer Linnaeus's *Pistacia sumaruba* from the incorrect genus into *Bursera*, creating the name *B. simaruba* we use today.

Catesby and others of the time used an old European medical term as the common name for these plants, gum-elemí (English) and *gomme elemi* (French). That designation was in use in the Bahamas where Catesby drew the plants, and probably through most of the remaining European settlements in the Americas. However, the term was comparatively new in Europe, first noted in a Latin grammar published in Rome in 1517. In the interim it spread to Italian as *elemi*, French as *élémi*, and Portuguese as *gumilemi*. Some think that the word was brought into Europe via the Silk Road with Arabic traders as *lami*, and later had the English "gum" added. Regardless, it was a long-held tradition to treat certain ailments with plasters and ointments made of this aromatic tree gum, regardless of which species it came from. Perhaps the first gum-elemí came from *Canarium* (Philippines). Later, gum-elemí came from the Caribbean (*B. simaruba*) or Brazil (*Protium*). All three belong to the Burseraceae.

In the New World people created an array of variations on this Latin-based English name. Among the variations on the name are simply elemi, American elemi or West Indian elemí, gum elemi, gum-alamí, gummi elemi, gomali, gomalimi, gum elemy, gum tree (Bahamas, Dutch Antilles), lime tree (Dutch Antilles), and even aerial yam. Most of the designations are now archaic and have been replaced by other names, but they were widely used by different languages for many years. Now, they have been replaced by a name created by African slaves. That name is "gumbo limbo" [gumbo-limbo, gumbolimbo] (Florida to Panama), which may have been taken from *ngombo ulimbo* (slave's birdlime) (Austin 1978). Sometimes there are color modifiers such as *gumbolimbo blanco* (white *Bur sera*, Belize), red gumbo limbo (Belize), or white gumbolimbo (Belize).

French speakers preferred to emphasize the gum part of the old designation, and use variations on that. They call it *gomme mombin* (gum tree, Granada), *gommier* (gum tree, Guadeloupe), *gommier barrière* (fence gum tree, alluding to its use for living fences, Guadeloupe), *gommier blanc* (white gum tree, Haiti), *gommier maudit* (wretched gum tree, St. Lucia), *gommier rouge* (red gum tree, Guadeloupe, Martinique), a mixture of English and French with peeling-bark *gommier* (Trinidad), and dryland *gommier* (Trinidad).

Judging from the number of names and the worldwide use of related plants, *B. simaruba* must be one of the most widely used plants in the American tropics. However, because it is one of the most aromatic, it is reasonable that it was used so much. The species has more than 100 common names from essentially all people within its range. *Bursera simaruba* ranges from Sonora in northwestern and Tamaulipas in northeastern Mexico, southern Florida south through the Bahamas, West Indies, the remaining tropical states in Mexico through Central America to Colombia and Venezuela and Guyana. Among the maladies treated with the plants are ache (stomach), bite (snake), calculus, cancer (stomach), cystitis, debility, diarrhea, dropsy, dysentery, enterorrhagia, fever, gangrene, hernia, impotence, intestine problems, kneecap problems, lactagogue (veterinary), nephritis, obesity, rash, renitis, rheumatism, sores, stomach problems, strain,

swelling, tumors, hunger, venereal problems, wounds, and yellow fever (Austin 1978, Morton 1981). It has also been used as a depilatory, diaphoretic, diuretic, insect repellent, purgative, and vulnerary. The preparation was considered antiseptic, aphrodisiac, and expectorant.

Following the similarity to pistachio and mastic, the plants became in Spanish *almácigo* (mastic, Puerto Rico, Costa Rica, Dominican Republic, Panama, Colombia), *almácigo blanco* (white mastic), *almácigo Colorado* (red mastic, Cuba), *almácigo encarnado* (flesh-colored mastic, Puerto Rico). Even in English some called them mastic trees, a name usually applied to *Sideroxylon*.

Because of the aromatic gum, the natives of the Americas had been using the trees long before the Europeans arrived. A common use was as incense. So, the plants became incense tree in English, rendered in French *bois d'encens*, and in Spanish *palo de incenso*. That use also gave rise to common names including balsam tree, turpentine tree, and torchwood. Two words for the aromatic resin were introduced into Europe from the Aztecs of Mexico. One of these was *tacamahaca* [*takahamaca*, *tacamahac*, *tamacahack*, *taccamahac*, *tacamacha*, *tacka mahacca*, *thecomahaca*, *tacamaque*]. This apparently came from the Náhuatl word *tecomahiyac* (*tecomatl*, clay vase+*xicatl*, white). Nicholas Monardes in 1569 and the English translation by John Frampton of 1577 were perhaps the first to introduce this term to Europeans. The English translation says, "Thei do brying out of the new Spain an other kinde of Gumme or Rosine, that the Indians doeth call tacamahaca...it is a Rosine taken out by incision of a tree...and is of a verie sweete smell." The Mexicans used the gum to treat swellings of any body part, and to treat colds, flatulence, toothache, stomachache, women's problems, headache, sciatica, aching joints, and the complexion. Much later the name *tacamahaca* was confused or misapplied to the temperate *Populus balsamifera* to the confusion of many (e.g., Vogel 1970).

Oddly, neither Monardes nor Frampton seem to realize *tacamahaca* was the same as *copal*. They say, "The Copall is a Rosine verie white, and of muche brightnesse, it is brought in certaine greate peeces, which are...verie cleare." Later, "With this Copall the Indians did make perfumes in their sacrifices, and so the use thereof was frequented in the Temples, for their priestes." Monardes goes on to describe how the incense is used against head colds and other respiratory problems. That indigenous word for incense stuck in all European languages as *copal* [*copalillo*] (*copalli*, incense, Náhuatl, Mexico). The source of the incense was the *copalcuahuitl* (incense tree, Náhuatl). Catholic priests were also quick to realize the value of this incense and adapted it to their religious services.

Each linguistic group had its own name for the trees, some referring to incense, and others to other traits. In other languages this tree was known as *suchicopal* (Tabasco), *yalaguito* (*yala*, perfume, *quito*, from *quie*, flower, and *ito*, small, Zapotec), *cachibú* (probably Carib *kasibu*, sharp-pointed, Cuba), *caraña* (name given to Clusiaceae, Costa Rica), *carate* (synonym of *jagua* [tree], Panama), *caratero* (tree, Colombia, Panama), *kal-no* (choked or clogged up, perhaps to indicate the medicinal use, Maya, Yucatán), *limsi* (Miskito, Nicaragua), *lon-sha-la-ec* (Chontal, Oaxaca), *mara* [*maro*, *marero*] (from Latin *marum*, Mediterranean *Teucrium marum*), *percha* (perhaps because the sap resembles gutta percha, or a mispronunciation of *piocha*), *pom*, *quiote* (Sinaloa), *resbalamono* (Colombia, Panama), *tasun* [*taxun*] (Tepehua, Veracruz), *ta'sun* [*tasuni*, *tasun*, *tsun*] (Totonac, Veracruz, Puebla), *teuc*, *tsic* (Otomí, Veracruz), *tsok* (Oaxaca), and

*tzaca* (Huastec, San Luis Potosí). Other variations on the medicinal theme are conveyed by variations on *jiote* [*jicote*, *jinote*] (from *xiuitl*, herb, Náhuatl, Sinaloa, Guatemala, El Salvador, Honduras, Costa Rica), *jiñocauaba* [*jiñocaube*, *jiñocuave*, *jiñote*, *jiniquite*, *jino*] (Nicaragua, Costa Rica, Panama), *jiote colorado* (red leaf, Sinaloa), *palo chino* (curly tree, Yucatán, Guatemala, Honduras, Belize), or simply *chino* (curly, Guatemala), and *palo jiote* (Veracruz, Tabasco, Chiapas, Guatemala, Honduras, El Salvador, Belize). Similarly, medical uses are implied in *chicchica* (maybe from Náhuatl *chichica*, bitter or sour), and *chicohuiste* [*choco-huite*, *chocohuite*, *chocogüite*, *chohuite*, *cohuite*] (*chichica*, bitter+*cuahuatl*, tree, Náhuatl, Chiapas), and *hupuk* [*huk'up*] (something one introduces [as medicine], Maya, Yucatán).

Still others were impressed by the peeling bark of the trees. People from temperate areas compared it with *Betula*, and called it birch gum, birch, birchwood, red birch, and West Indian birch. Natives also noticed the trait and call it *pellejudo* (with much skin, Guerrero), *chinacahuite* (*chinamitl*, separate, as in the peeling bark, *cuahuatl*, tree, Náhuatl, Guatemala), *chacah* [*chaca*, *chachah*, *chakah*, *chakag*, *chak chakaj*, *chakan*, *cajha*, *ca-ch*, *ca-cah*, *cha-ca*, *xa-ca*, *xaka*] (*chacah*, cooked, boiled, because of the appearance of the exfoliating bark on the trunk that makes it appear to have been cooked, Maya, Tamaulipas, Veracruz, Tabasco, Yucatan, Quintana Roo, Belize), *chacaj* (Tojolobal, Chiapas), *chaca piocha* (Tamaulipas), *chacah Colorado* (red *chacah*, Maya, Yucatan), *chacai* (perhaps a loan-word from Mayan to Náhuatl, Puebla), *chacajiota* (*chacah* leaf, Náhuatl, Puebla, Veracruz), *sak chaka* [*sac-chacah*] (white *chacah*, Maya, Yucatán), and *tzaca*. Perhaps the names *ginicuite* (*xini*, peeling, *cuahutil*, tree, Náhuatl) and *jenequite*, are related. In Florida, the Seminoles called it *ahiciáhki* (peeling bark, Mikasuki).

Europeans also compared the trees with the red skin of the American natives. They call it naked Indian (Panama), naked boy, *indien nue* (naked Indian, French), *indio desnudo* (naked Indian, Belize, Panama), *indio en cueros* (naked Indian, literally, in skin), *indio peludo* (shaggy Indian, Belize), *pellejo de indio* (Indian's skin), *palo Colorado* (red tree, Sinaloa), *palo retinto* (chocolate-colored tree, Sinaloa to Tamaulipas, Veracruz, Yucatán, Chiapas), *palo mulato* (mulato tree, Sonora, Nayarit, Tepic, Chiapas, Tabasco, Oaxaca, Veracruz, Yucatan), *palumulat* (mulato tree, Pima, Sonora), *mulato* (Oaxaca), and *to'oro mulato* (mulato gumbo limbo, Mayo, Sonora).

Other common names either confuse the trees with other species or make comparisons with them. These include *guacimo* (a name usually given to *Guazuma ulmifolia*, Malvaceae), *jobo* (Spanish, a name usually given to *Spondias mombin*), *gomme mombin* (mombin gum tree, Granada), and *jobo pelón* (*Spondias* with peeling bark, Spanish). In Costa Rica it is simply called *aceitero* (olive), but everyone knows the difference between it and the cultivated olive (*Olea europea*). In the Dutch Antilles it is *paaloe sieja doesji* (tree seed sweet), *paalkoe sieja maatsjoe* (tree seed forest), *palu di sia corra* (copper seed tree), *palu di sia machu* (male seed tree), *sia* (seed), and *sia blancu* [*sieja blanco*] (white seed).

Some names refer to uses, as in *copón* (big cup?, Honduras), *azucarero* (sugar giver). However, the Creek speakers among the Seminoles have a direct name for the tree they learned about from the Spanish—*itotiná:span* (*eto*, tree, *espane*, Spanish).

***Byrsonima*: Locust Berry**

(Named by Louis C.M.Richard, 1754–1821, and Karl S.Kunth, 1788–1850, from Greek *byrso*, hide and *nema*, thread, referring to the bark of some species)

***Byrsonima lucida*.** a. Flowering branch, b. Node showing clashing leaf bases, c. T-shaped trichomes from leaf surface, side and above, greatly magnified, d. Flower bud with basal bract and pair of bracteoles and glands on sepals, e. Flower from above, f. Flower from below, g. Flower longitudinally dissected, h. Stamens, i. Floral diagram, j. Branch with fruits. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

In the Everglades where periodic fires maintain the pine flatwoods, the locust berry (*Byrsonima lucida*) is a small shrub, rarely over a meter (3 feet) or so tall. The farther south one goes in the Florida Keys, especially in the older hammock forests, the larger the plants. On the ecotone between hammock and salt marsh or even marl flats in some of the southern Keys the species reaches tree size. When I first read that they reached 7.6 m (25 feet) tall, and had trunks 15 cm (6 inches) in diameter, I did not believe it. But then, I

had only seen the Everglades National Park plants. Later, I saw them on Cudjoe Key, and they matched the book descriptions—maybe exceeded them.

In the spring and summer these shrubs and trees are covered with small whitish to pale pink flowers that turn darker pink when they have been pollinated. For years, I thought that they were pollinated by bees and that they must provide nectar and pollen for them. I was right on the first point, but wrong on the second. One of the unique traits of the Malphigiaceae are the glands on the outside of the sepals. Those glands secrete an oil that is highly visible in some family members, but obscure in others. In either case, that oil is gathered by bees to construct their nests (Sazima and Sazima 1989, Steiner and Whitehead 1991).

People too have long used the genus *Byrsonima*. The genus is mostly rich in tannins that have been used to cure hides across the range. *Byrsonima lucida* is among those used as the name *bois tan* (tanner's tree, French Antilles) attests. Those same tannins have made *Byrsonima* useful for other purposes. Fruits and other parts are astringent and have been used against dysentery. Roots and bark have been used to combat that common problem in tropical areas and also have been used as a fungicide, against fevers and catarrh, to treat snakebite, and as a pectoral (Morton 1981). Some of the common names suggest long association with humans as medicines and for other uses. Medicinal names include *bois dysentérique* (dysentery tree, French Antilles), *doncella* (the Virgin, Dominican Republic), *sangre de doncilla* (blood of the Virgin, Cuba, Puerto Rico), *carne de doncilla* (Virgin's flesh, Cuba). Others probably alluding to uses of the wood or bark include candle-berry (Bahamas), *maricao* (Puerto Rico), *peralejo de pinares* (*Byrsonima* of the pines, Cuba), *piragua* (Taino, Cuba), and *sabica de costa* (coastal *sabícu*; *sabícu* is *Lysiloma sabicu*, Cuba).

*Byrsonima lucida* probably was used for dyes as related plants have been. Some species make brown-red dyes that prolong the life of the products colored because of the tannins and other chemicals. For example, *B. crassifolia* furnished one of the most important dyes in Amazonia. Because of the tannins and associated compounds, the plant was used by *caboclos* (river people) along the Amazon to make a brown-red dye that was used for fishing lines, sails, and clothes (LeCointe 1947:319). Apparently, *B. lucida* has not been studied, but several species in the genus contain beta-amalin in the bark that makes it active against bacteria (Mors et al. 2000). In many places, the wood is used for carving small objects and for furniture (Little and Wadsworth 1964, Morton 1981).

Fruits of locust berry are edible, although that name does not seem to imply that they are. Some compare them positively to cranberries, while others say they have a "soapy" taste. Many of their common names allude to edible fruits, including *aceituna* (olive, Puerto Rico), gooseberry (Anegada), guana-berry (Bahamas), *merusier doré* (golden cherry, French Antilles).

The plants in Florida and the Bahamas are in the northern part of their range. Otherwise, they grow in Cuba, Hispaniola, Puerto Rico, the Virgin Islands, and from Anguilla and Barbuda to Barbados. Yet, this is one of the least used species in the genus. In Central and South America, there are others more famous for human utilization.

Perhaps the most famous of the group are several species called in Brazil *muruci* (from *muri'si*, Tupí). These include *B. crassifolia* and *B. verbascifolia*, among others. These species are called by several local names including *murici-do-campo* (wild murici), *murici-açu* (big murici), *murici-da-praia* (beach murici), *murici-da-mata* (forest murici),

*murici-miúdo* (small murici), *murici-rasteiro* (prostrate murici), *murici-penima* (murici the size of a penny), *chaparro* (thicket), *orelha-de-burro* (donkey's ear), *matega* (tea tree), *caáaçu* (big plant, Tupí), *pau-de-curtume* (tanning tree), *pessegueiro-de-curtume* (tanning prune). The best-tasting and most widely used for food is *B. crassifolia*. In Brazilian markets, they are almost always just called *murici*. They may be found fresh in markets, or made into juices, wines, or even ice cream. The taste is delightful and even temperate palates quickly appreciate these tropical flavors. Vacationers in Brazil even pack the fruits in water with sugar, and they are said to keep for as long as 2 weeks (Cavalcante 1976).

Europeans were first introduced to these delectables by Georg Marggraf [Marcgrav, Marcgrave] in the middle 1600s when he wrote, that *Murici* has “*bagos da figura e tamanho dos frutos da roseira braba, que são comidos*” (berries of the shape and size of the fruits of the wild rose, that are eaten). Now, *B. crassifolia* is so popular, for ornament and fruits, that it is grown up the Pacific coast of Mexico and even into southern California. In these areas the berries are eaten fresh, with salt, in soups, or as flavoring on meat.

Many of these same species are used medicinally in Amazonia (LeCointe 1947, Mors et al. 2000). The bark is made into a cough medicine and used to treat tuberculosis and other bronchial inflammations. In all the species, the berries are astringent and antidiysenteric. In some the bark and berries are mildly laxative. Some are considered diuretic and emetic and have been used against syphilis.

Many other people use *B. crassifolia*, and it has common names throughout much of its range. In Yucatan, the Maya call it *chi*. The Zapotec of Oaxaca call it *mami-hña*. However, the most widely used name is a variant on the Aztec name *nantzincuahuitl* [*nanzinxócotl*] (*nantzintli* or *nantli*, mother, *cahuitl*, tree). This is typically shortened to a variant of the first word and becomes *nance* [*nanche*, *nanchi*, *nanantze*, *nancis*, *nandzin*], or *nance agrio* (sour nance), *nanche amarillo* (yellow nance), *nance dulce* (sweet nance), and *nanche de perro* (dog's nance) throughout southern Mexico.

Florida's *Byrsonima* is “locust-berry.” That sounds like a derogatory name. Surely, it means something only a foraging swarm of locust grasshoppers would eat. However, the name turns out to be highly complimentary. It is true that the first meaning now in use in English of the word is for the rapacious insects. However, a historically important meaning—arguably more important—was a name of leguminous trees, particularly the locust tree or carob (*Ceratonia siliqua*). These trees were important food in the eastern Mediterranean, and reputedly provided the main food for John the Baptist of the Bible.

So, comparing the bushes and trees in the American tropics with that religious personage and his food surely originally was meant as a compliment. This interpretation is further supported by evoking the Virgin Mary in several of the common names (e.g., *sangre de doncilla*, *came de doncilla*). Plants important enough to be associated with these holy biblical icons have been considered important regardless of how unassuming they now appear.

Moreover, there are several other “locust” trees in the New World, including temperate honey locust (*Gleditsia* spp.) and black locust (*Robinia pseudoacacia*). Within the tropics, the most important locust is the West Indian locust (*Hymenaea coubaril*). The West Indian locust not only figures prominently in medicines, but its ancestors have also left behind much of the fossilized resin we call amber.

# C

## ***Caesalpinia*: Gray Nicker**

(Named for Andrea Caesalpino)

***Caesalpinia bonduc*. Drawn by  
P.N.Honychurch.**

Andrea Caesalpino (Andreas Caesalpinus, 1519–1603) was an Italian who studied at the University in Pisa with botanist Luc Ghini (1490–1556) and anatomist Realdo Colombo (ca. 1510–1559). Later, Caesalpino was the prefect of the first botanical garden in Pisa, and in 1563 he founded the second garden. That was surely why Linnaeus named the genus *Caesalpinia* in his honor in 1753. In continuing that name Linnaeus followed the lead of Hans Sloane, John Ray, and Mark Catesby who had studied the plants before him.

The gray nicker (*Caesalpinia bonduc*) grows in coastal regions on beaches or near mangroves. Every part of the plant except the flowers is armed with recurved spines that discourage close examination by ripping at the skin and clothes. Once the yellow, comparatively inconspicuous flowers are gone, they are replaced by spiny brown pods that contain the gray, marble-like seeds. Those seeds gave rise to the primary English name, “nicker.” This ancient word has an obscure origin, as does its base, “nick.” Probably, the name was first an allusion to the mythical water demon also known as a *kelpie* (Gaelic, *cailpech*). As such, it dates back to the time of Beowulf (6th century

B.C.). It may date back to the Sanskrit word *nij*, to wash. Regardless of its exact derivation, its association with the sea resulted in it being applied to these plants. The word took on many meanings over the years, including “one who cheats at games” (from the 1660s), “one who fits objects nicely” (from the 1670s), and a game (from the 1670s). From the game, it came to mean a marble. In the Caribbean, it has most recently meant to compare the round seeds of these vines to marbles. However, that usage is recent, dating from Hans Sloane’s 1707 mention of nicker-tree in Jamaica.

Variations on the nicker theme include ash-colored nicker (English Antilles), *canique* (nicker, Hispaniola), *canique grise* (gray nicker, Guadeloupe, Martinique), gray nicker (Florida, Bahamas, Barbados), horse nicker (Barbados), and nicker nut (Bahamas to Panama).

Comparison to other legumes include *haba de San Antonio* (San Antonio’s fava bean, Veracruz), *jabilla* (little fava, Veracruz), *habilla de mar* (little sea fava, Sinaloa), *juquirirana* (from Tupí, *yuki’ri*, the name of *Machaerium ferox+rana*, false, Brazil), *taray* (a name usually given to *Eysendhartia polystachya* in Veracruz and to *Salix chilensis* in the central part of the country), and simply seabean (Panama).

Several places have confused *C. bonduc* with the Brazil wood (*C. echinata*) that was so much in demand from the Brazilian coastal forests that it was almost harvested to extinction in the 1800s. These are *bois de Brésil* (Brazil wood, French Antilles), *brasil* (coals, also the original comparison with Brazil wood because of the red color, Oaxaca), *brasilete Colorado* (red Brazil wood, Cuba), and *palo fernambuco* (Pernambuco tree, Cuba).

Some of the names refer to the downright nasty, spiny nature of the plants. These are brier bush (English Antilles), brier (English Antilles), *guacolote* [*cascalote*, *nascalotl*, *huiscolote*] (perhaps derived from *huitzcocólotl*, spiny branch, Náhuatl; Cuba, Veracruz), *guacolote prieto* (black spiny branch, Cuba), *inimbó* (from Tupí, *inimicu*, hostile, Brazil), *inimboja* (very hostile, Brazil), *mato* (thicket, Panama), *mato azul* (blue bush, Puerto Rico), *silva da praia* (beach tree, Brazil), and *villa de mar* (beach villa, Spanish Antilles).

Other names have compared the seeds to plants, animals, and other objects. Some of these are likely to have dual meanings and also refer to medicinal uses. Among these are *arriózes* (originally the name given the ball from a muzzle-loading gun [blunderbuss], now applied to the seeds of this legume, Brazil), *bonduc* (derived from the Arabic *bunduk*, a little ball, Jamaica), *cojónes de gato* (cat testicles, Yucatan), *garrapata de playa* (beach tick, Venezuela), *mato de playa* (beach bush, Puerto Rico), *oeil de chat* (cat’s eye, French Antilles), *ojo de águila* (eagle’s eye, Mexico), *ojo de venado* (deer’s eye, Sinaloa), *olho de gato* (cat’s eye, Brazil), *piedra del águila* (eagle’s stone, Oaxaca), *quaritt-oeil-de-chat* (cat’s fourth eye, French Antilles), warree seed (Belize), and *yeau de chat* [*z’yeau a chatte*] (cat eye, Guadeloupe).

However, one of the most important categories of names includes the many references to medicinal application. These often allude to the use of the seeds to combat malarial fevers. As the seeds have been used around the world for this purpose, they have been called the “quinine of the poor.” Names related to this use are *calentura* (heat or fire, Panama), fever nut (English Antilles), *graines quinine* (quinine seed, Hispaniola), *mate de costa* (coastal tea, Hispaniola), *mate* (tea, Hispaniola), *quasha* (probably a variant of *quassia*, West Indies), *quinine* (Hispaniola), and *quinine jaune* (yellow quinine, Hispaniola).

When names are old enough not to have a translation, they usually have been in the language so long that they designate specific ideas or objects. It is likely that *tikó:li* (Mikasuki) and *i:kofkapó:yî* (Creek) belong in this category. It appears that the Creek name is based on *ekofkv*, breechclout, and *po:y-i*, completed, but that makes no obvious sense, unless it means that the spines might tear off even that garment. While Sturtevant (1955) found no Seminoles who knew of uses for the plants, he noted that there was a necklace of its seeds in a museum collection. Most likely, the informants who worked with Sturtevant simply had lost the old medicinal uses.

Indeed, the use of the oils in the seeds (up to 23% by volume) in medicines is founded on a variety of potent chemicals, especially the bitter bonducin, which is tonic and antiperiodic (Hocking 1997). Also present is a group of furanoditerpenes designated as caesalpins (Pascoe et al. 1986). These chemicals surely account for the seeds being used around the world since the plants were adopted by Americans and Europeans when they were brought back from the tropics. The seeds have also been used to combat colic, convulsions, dropsy, fever, hydrocele, leprosy, palsy, to remove pimples, against snakebite, to soften skin, as a tonic, against toothache and venereal diseases, and as a vesicant (Morton 1981, Mors et al. 2000).

The seeds are used in necklaces and in maracas. They are carried by natives as talismans or amulets, and they are still used as marbles.

A second species has been continually confused with this one, even though it has yellow seeds. This is *C. major*, yellow nicker, *guacolote amarillo*, *mato de playa*. The seeds of that species are so similar to the fruits of the mastic tree (*Sideroxylon foetidissimum*) that I have mistaken them for those. I only realized my error when I noticed that there was no mastic present. Like the mastic, these yellow seeds are almost certainly dispersed in Florida by the white-crowned pigeon (*Columba leucocephala*). That dispersal method is so different from the gray nicker that it makes the yellow species highly local throughout its range. Seeds of the gray nicker are dispersed by ocean currents. They travel remarkable distances, and the species is pan-tropical. Almost unbelievably, the seeds wash ashore in Scotland where they historically were known as Molucca beans. The Scots, however, had another name for all sea beans. They called them *arna Moire* (Mary's kidney, Gaelic), and they prized them.

### *Cakile*

(From the old Arabic words *kakeleh*, *qaqila*, or *qaqulla*, the name for cardamom, *Elettaria cardamomum*)

***Cakile lanceolata*.** a. Tip of branch with fruit and leaves, b. Tip of branch with mature fruit, c. Fruit. *Drawn by Vivian Frazier.* From Correll and Correll 1972.

*eruca marina* (ocean arrugula, Portuguese); *oruga marina* (ocean arugula, Spanish); *roquette de mer* (sea rocket, French); sea rocket ("rocket" is from Middle French *roquette*, which came from Old Italian *rochette*, a diminutive form of *ruca*, the garden rocket or arugula, *Eruca*; first in English by ca. 1530)

*Meersenf* (sea mustard, German)

*radicetta marina* (sea radish, Italian); *strandreddik* (seashore radish, Norwegian)

***Cakile edentula* (edible)**

*caquillier* (sea-rocket plant, Quebec)

[American] sea-rocket (Florida)

***Cakile lanceolata* (with leaves shaped like lance points)**

*berro de costa* (coastal water cress, Cuba)

*gardenia* (misapplication of *Gardenia*?, Bahamas) *mostacilla del mar* (sea mustard, Puerto Rico)

pork bush (Bahamas)

[southern, coastal] sea-rocket (Florida, Bahamas, Puerto Rico)

There are two species of *Cakile* on the shores of Europe and five in North America. The others are scattered around the globe (Kartesz 1994, Mabberley 1997). A total of seven species are now recognized, although Philip Miller knew only one when he described the genus in 1754.

People in southern Labrador have long cooked the plants as greens, and the common names suggest that other people have done the same. Fernald et al. (1958) were not overly enthusiastic about them. Kalm ([1753–1761] 1972) noted that people in the province of Quebec at Cap aux Oyes pounded the root, “mixed with flour, and eaten here, when there is a scarcity of bread.” Tussac (1808–1827) recorded that blacks in the Antilles boiled the leaves and put them on persistent sores as a deterrent.

### ***Callicarpa*: Beauty Berry**

(Greek, *kalli*, beautiful, *karpos*, fruit)

To me the generic name of these plants is one of Linnaeus’s strokes of genius—apparently without borrowing from anyone this time. Four authors had discussed this plant before him, and the names they used were lackluster. The nearest to creating something of interest was John Mitchell’s *Sphondylococcus* (*spondyl*, vertebra, *coccus*, fruit) of 1748. Plukenet in 1696, Catesby in 1734, and Gronovius in 1739 used long but unimaginative phrase names. Linnaeus had actually seen these plants growing in the Uppsala gardens, and he called them *Callicarpa*, or beauty berry in English.

If you are walking in a pinelands in the southeastern United States, the clusters of small, purple, beautiful berries are sure to catch your attention. These small shrubs grow to about head high, and there may be a half-dozen rings (verticils) of fruit clusters scattered up the stems. In the late summer and fall, the fruits also catch the eyes of birds. These feathered dispersers spread beauty berry seeds around with a load of nutrients that helps the young plants get started in life. When the shrubs are in flower, they are not that showy, but fruit clusters are a completely different situation.

This is one of the American species that was taken into cultivation in Europe and consequently admired for its beauty and little else. The memory of its utility among native people and colonists faded and has almost disappeared. Views were different 230 years ago.

When William Bartram was traveling through southern Georgia in late 1773 or early 1774, he commented that the people of the area had long grown the plants. Around old Indian settlements on the Little River, he wrote, “I observed, in the antient [*sic*] cultivated fields, 1. Diospyros, 2. Gleditsia triacanthos, 3. Prunus Chicasaw, 4. *Callicarpa*, 5. *Morus rubra*, 6. *Juglans exaltata*, 7. *Juglans nigra*, which inform us, that these trees were cultivated by the ancients, on account of their fruit, as being wholesome and nourishing food” (Bartram [1791] 1958). While some might argue that the fruits of *Callicarpa* are not that good or nourishing, his observation presaged the worldwide cultivation of this species. In March of 1774, he was in St. Augustine, Florida, where he found a large earthworks and other signs of long occupation. He wrote, “There grew in the old fields on these heights great quantities of *Callicarpa*” (Bartram [1791] 1958). Bartram mentions *Callicarpa* at least 15 times, and in 6 of these comments associates it with being cultivated by people of the Creek Nation.

We might question the reasons for the plants' presence in the oldfields. Perhaps they were there simply because the Creeks permitted them to remain and did not cultivate them, or perhaps they grew there because birds spread their seeds into cultivated lands. However, I am inclined to believe Bartram because he talked with the local people and learned as much about their customs as he could. He was greatly interested in their cultivated and medicinal plants.

This interest in the plants by the Creeks and their relatives is reasonable because we have common names for the plants in Mikasuki (*kalá:cí:rá:pí*, tree having shells, perhaps because they note that snakes lay eggs among the roots), Creek (*ca:tapholó:ta* also transcribed as *catv-folotv*, red worm), and Choctaw (*shoklapa*, maybe *shokulbi*, the inside corner of a field,

*Callicarpa americana*. Drawn by  
P.N.Honychurch.

where the plants maybe grew). Koasati said *cosimilpá* (*cosí*, wren, *im*, its, *ilpá*, food). This is probably the plant the Chickasaw called *nita' lobahli* (*nita'*, bear, *lobahli'*, raisin). Perhaps the Alabama name gives more indication of their views—*haakhimbatka* or *hak-himbatka* (*haakha*, pelican, *im*, its, *balka*, raisin).

We do know that the Alabama used the plants in sweat baths against edema and malaria (Taylor 1940). The Choctaw used them against colic (Bushnell 1909). The Seminoles too had a number of uses, but those that have been recorded include remedies for what they call "Snake Sickness" and "Urine Retention Sickness" (Swanton 1928a). For Snake Sickness, the medicine is applied to the outside of the body as a steam, but the patient also drank some of the liquid. In Urine Retention Sickness, a decoction effects a diuresis that cleans the kidneys and bladder. However, that may not be all that is going on because the remedy is also thought to have been used for a number of urinary problems,

including gallstones and bladder disorders. There is even some indication that it may have been used against gonorrhea. Chemical and laboratory studies have shown that root decoctions of the plants have antiviral activity against measles and polio pathogens (Hocking 1997). Perhaps there is also activity against other microbes. Although details are not given, there is one record of the plants being involved in a remedy for skin cancer (Duke 2003).

Because the foliage and other parts of these shrubs are aromatic, they have been used in medicinal teas in North America and elsewhere. In Cuba the species is called *filigrana morada* (purple filigree), or simply *filigrana* (filigree, but particularly a name given to this plant). That name links the medicine with *Lantana camara*, which Cubans also called *filigrana*. The name also links *Callicarpa* with *L. involucrata* because it is called *filigrana cimarrona*. All three are in the Verbenaceae and have similar odors.

In Cuba, *Callicarpa* is also called *filigrana de mazorca* (young corn filigree), although its relationship to corn is obscure. Users also understand the plant's relationship with habitats because they also call it *filigrana de piña* (filigree of the pine) and *filigrana de piñar* (filigree of the pinewoods). On that island, a medicinal tea of the leaves and small branches is particularly popular against chest inflammations (Roig 1945).

The other names for these plants revolve mostly around two themes. One is the fruit, and includes American beautyberry (Europe), bunchberry (USA), foxberry (USA), French mulberry (Europe), purple beautyberry (USA), *Schönfrucht amerikanische* (American beautyberry, German), and turkeyberry (USA). Perhaps sour-bush (USA) also refers to the fruits, but it might just as well apply to the tea that is made from the plants.

The other theme among names, oddly enough, compares *Callicarpa* with the mulberry (*Morus* spp.). These names include Bermuda mulberry (USA), dwarf mulberry (USA), and Spanish mulberry (USA). There is nothing about the vegetative parts that looks much like a mulberry; perhaps the color of the fruit reminded someone of that tree.

This shrub is one of those that is basically North American. Beauty berry grows from Florida west to Texas and north to Maryland and Oklahoma. However, *C. americana* also occurs outside that region in places where it seems odd that it should grow including Cuba, Coahuila, and Bermuda. That it would grow in Coahuila, Mexico, is not too surprising because Texas is just next door. Yet, how did the plants get to Bermuda and Cuba?

Several of the species in the genus have been used as fish poison, and *C. americana* is among them. Apparently, the only species that has been studied chemically in this regard is *C. candidans* (southern Asia, Indonesia to Australia), and it contains callicarpone. That chemical is said to have a potency equal to rotenone (derived from the legume *Derris*), which makes it powerful indeed (Hocking 1997).

One of the species apparently closely related to *C. americana* is *C. acuminata*, which ranges from Mexico to Colombia and Bolivia. This species is considerably larger than the Florida plants and may grow to 6 m. However, it too has a strong tendency to coppice, and produces clumps of many stems like *C. americana*. The predominant common name for *C. acuminata* is the Mayan *sak-puy'in* [*sak-pukin*, *zacpucin*] (*sak*, white), but it is also known simply as *puk'in*. The simple name is ancient enough that no translation exists—that is simply the name of the species. Other Mexican names include *elele'* [*elté*] (spring tree, Huastec, Hidalgo, San Luis Potosí), *alahuete* (perhaps an incorrect transcription of *elele'*, Huastec, San Luis Potosí), *granadilla* (a name usually given to *Passiflora*,

Chiapas), *hierba de la chachalaca* (Chachalaca herb, the bird *Ortalis*, Mexico), *patsumacáshil* (Totonac, Veracruz), and *uvilla* (little grape, Tamaulipas).

This species grows all along the Mexican east coast and well into the interior. Like its U.S. counterpart, this species has a variety of medicinal uses. The Huastec people of central eastern Mexico have good documentation of usage (Alcorn 1984). They use the plants in root decoctions against internal problems, including hemorrhage associated with childbirth. For that problem the woman is asked to drink one small glassful. The Huastec people also mix the roots with other plants to make a decoction that treats constipation and inability to urinate. However, they are not limited to medicinal application of the plants. Leaves are used as dish scrubbers. Stems are burned as one of the most commonly preferred fuels and also used as supports for bean vines and as one type of rafter in house construction.

Among the uses by others are as a diaphoretic, a purgative, and, oddly enough, a decoction is given to halt dysentery and diarrhea. That dual usage is common in indigenous medicines, and the concentrations often vary—concentrated doses cause evacuation of the bowels, and weaker doses halt that problem. However, usually that dual usage philosophy is not easily separated from the idea that, if you have a problem, a good laxative will clean it out and get rid of it.

### *Calycanthus*

(Linnaeus created the genus from Greek *kalyx*, a calyx, and *anthos*, flower, because the calyx and petals are the same color)

***Calycanthus floridus*.** From Britton and Brown 1897.

***Calycanthus floridus*** (flowering) bubby-blossoms [bubby-shrub] (“bubby” is an English word meaning breast, in use by ca. 1686; cognates are German *Bübbi*, and French *poupe*; any connection between breasts and these flowers is obscure unless it might be the color)

Carolina allspice (“allspice” compares *Calycanthus* to *Pimenta dioica*, a species that is thought to combine the flavors of cinnamon,

*Cinnamomum verum*, nutmeg, *Myristica fragrans*, and cloves, *Syzygium aromaticum*; the comparison dates from about 1601; most places in the world call the fruits of *P. dioica* either “pimento” or some variation on that Spanish word)

*Gewürzstrauch* (spice bush, German)

pineapple-shrub (presumably because of the fragrance of the crushed flowers)

strawberry bush (applied by 1847 because the fruits resemble the strawberry in their red color)

[common, South Carolina] sweet-shrub [sweet shrub]

As might be anticipated by the name “allspice,” the bark has been used as a substitute for cinnamon (Hedrick 1919, Yanovsky 1936). The Cherokee put the bark on children’s sores and made an infusion to relieve hives and to instill as eye drops. They also used the roots to create a strong emetic and a medicine for bladder problems (Hamel and Chiltoskey 1975, Moerman 1998). Fragrance from the flowers was used as perfume (Uphof 1968).

Hocking (1997) says that the seeds were used as a uterine tonic by indigenous people, but no other publication has been found verifying that. Sometimes now, a decoction of root bark or seeds is used to ease muscle cramps. That practice is not without danger because the seeds are poisonous and have been used by the Cherokees to destroy animals (Moerman 1998). Seeds contain calycanthine.

Porcher (1863), however, noted that it was used “as an antispasmodic tonic, in the cure of chronic agues. A strong decoction of the seed or bark of the root is given. The wood is strongly camphorated, especially the root, and Mr. Nuttall thinks [it] will probably produce this drug as abundantly as the *Laurus camphora*. Seeds seldom mature.”

The bark is cinnamon-clove scented, and the wood smells like camphor (Bremness 1994). The plants have been used as an aromatic stimulant and to treat malaria (Hocking 1997). In Alabama, the bark heated with lard and elder bark (*Sambucus*) forms “fire grease,” for use in treating burns (Hocking 1997).

### *Calyptranthes*

(Greek *kalyptra*, veil, lid, *anthos*, a flower, referring to the operculum of the flowers)

*Calyptranthes pallens* (pale in color)

*arrayán* (well-rooted, Dominican Republic)

lemon tree (Belize); *lemoncillo* (little lemon, Dominican Republic)

[pale] lid-flower [lidflower] (Florida, Puerto Rico)

spice-wood (Bahamas)

*tapón blanco* (white lid or stopper, Puerto Rico)

white stopper (Bahamas, Puerto Rico)

The Swede Olaf Swartz, a professor in Stockholm, named this genus in 1788 based on plants he found in Jamaica. Now there are 130 species known in the American tropics (Mabberley 1997). Some of the

***Calypttranthes pallens*.** a. Branch with flowers, b. Node and internodal ridge, c. Flower side view, with calyx lid still attached, d. Flower longitudinally dissected, e. Floral diagram, f. Fruiting branch, g. Fruit in transverse section, h. Embryo. *Drawn by Priscilla Fawcett.* Correll and Correll 1982.

species along the Amazon are fish dispersed, and the fruits of all are edible. Leaves of some have been used as spices.

Fruits are edible but not very good (Liogier 1974). The tree is considered medicinal in Belize (Balick et al. 2000).

### ***Campsis***

(From Greek *campsis*, curvature, an allusion to the curved stamens)

***Campsis radicans*** (rooting)  
*ampohko 'li'* (Chickasaw)

cow-itch [cow-vine, vine] (according to Small 1933, the plants are mistaken for poison ivy, *Toxicodendron radicans*, and that gave rise to the name—although cows do not get poison ivy; could it be that the word “cow” does not refer to the bovid, but is dialectic, first recorded in the 1500s, for “bundle of twigs”?)

trumpet-[creeper, vine, flower, honeysuckle] (“trumpet” came into English by the 1300s from French *trumpette*, a musical wind-instrument; the word has been used for plants with flowers resembling trumpets since 1705; Asa Gray, in his *First Lessons in Botany* published in 1857, is the first record found combining trumpet with creeper)

*Campsis radicans* is a unique member of the New World Bignoniaceae. There are only two species in the genus, with the other, *C. grandiflora*, native only to China (Mabberley 1997). The genus was created by Portuguese botanist João de Loureiro (1717–1791) in his *Flora Cochinchinensis* in 1790 for *C. grandiflora*.

Because the plants are so unique, it took people a long time to determine their relationships. Linnaeus called the New World plants *Tecoma radicans*. John K. Small (1933) too was unclear on the relationships, but he knew the vines were not part of *Tecoma*. He put this species in *Bignonia*, calling it *B. radicans*. In doing that, he mirrored what C.P. Thunberg had done with the Chinese species in 1784 when he called it *B. grandiflora*.

The Old World *Campsis* has been famous as a medicine since ancient times. It was mentioned in the *Shen nung pen tsao ching* (Shen Nung’s Herbal) of ca. 25 B.C. as a high-grade drug (Hsu 1986). Traditional use of the Chinese species was to remove postpartum obstructions and reduce bleeding.

As famous as the Chinese species is as medicine, it seems odd that so little has been recorded about the American plants. Steyermark (1963) considered *C. radicans* narcotic. Hocking (1997) found that the root was used as a diaphoretic and vulnerary in domestic medicine. The species is not mentioned by Porcher (1863), Millspaugh (1892), Uphof (1968), Vogel (1970), Foster and Duke (1990), Moerman (1998), or Duke et al. (2002).

### *Canavalia*

(Derived from the Malabar common name in India, *kavavali*, from *kanam*, forest, *valli*, climber)

jack-bean (this name was not in use until ca. 1885; perhaps the name originated with Malayalam *chakka*, the name of *Artocarpus*, which was rendered *jaca* in Portuguese by Gardia de Orta in 1563; as both were eaten in Asia, there may have been a transfer of names or equally possible is that it originated in English with the sense of “dwarfed or undersized,” as people began using the combination with several other plants in the 1800s)

sword-bean (from the large, flat shape of the legumes; apparently first applied to *Canavalia* in 1883)

*Canavalia rosea*. Drawn by  
P.N.Honychurch.

***Canavalia rosea*** (rose-color, of the flowers)

bay bean (Bahamas, Jamaica, Virgin Islands); *frijol de mar* (ocean bean, Honduras); *frijol de playa* (beach bean, Costa Rica); *haba de playa* (beach bean, Puerto Rico); *habichuela playera* (beach bean, Puerto Rico); sea [seaside] bean (Barbados, Jamaica, Cayman Islands)

horse bean (a name usually given to *C. ensiformis*, Bahamas)

June bean

*kumatará* [*kumatará*] (Carib, Suriname)

*mate de costa* (coastal plant, Cuba, Dominican Republic); *mato de playa* (beach plant, Puerto Rico)

*ouari* [*graines*] (maybe from West African slaves; the Katsina of Nigeria call one species *ro'bari*, Haiti)

*pois bord de mer* (seaside bean, Guadeloupe, Martinique); *pois cabrit* (goat bean, Guadeloupe, Martinique)

*pois liane* (bean vine, Haiti)

*pois Makendal* (Makendal's bean; François Makendal was a mystical figure who played an important role in the slave revolt in Haiti. He had only one arm and was well versed in voodoo. In the 1750s he organized a revolt against the French by going from plantation to plantation and talking to the slaves secretly. But the slaves were so afraid of retaliation that the movement failed. He was captured and tied to a post in *Cap Haitien* (*Cap Français* at the time). The French thought that by setting him on fire in front of all the slaves it would show them what happens when a slave revolts. But the flames burned the ropes that bound Makendal to the post and, according to the legend, he ran and disappeared before they could catch him. The slaves did not believe that he had died and the rebellion that he had started continued with Boukman; Guadeloupe, Martinique.)

*pois maldioc lan mer* (damned seaside bean, Haiti)

*pois zombi* (zombi bean, "zombi" is of Niger-Congo origin, akin to Kongo *nzambi*, god, Haiti)

*vonvon* (probably from the verb *aller*, as in *ils vont*, they go redoubled or “they go go,” as it is a running beach plant, Guadeloupe, Martinique)

Ignorance, they say, is bliss. So, my students and I were certainly blissful for years. At one time I had an anthropology student who was interested in plants used by people. She convinced me that the seeds of bay bean were edible by gathering a handful in the field, cracking the seed coats with her teeth, and eating the contents. I tried them, and they were tasty—nutty and sweet. Then, I read about the alkaloids and proteins found in the seeds, and discovered that they were considered by many to be toxic. I quit eating them and stopped showing students how to eat them.

However, there is a long history of people eating many of the species in *Canavalia*. For example, *C. ensiformis* (horse bean, overlook bean, sword bean) is grown as a vegetable in tropical areas (Sauer 1964, Purseglove 1968, Herklots 1972). The young pods are sliced and eaten like French beans (Goodding et al. 1965). Alain and Leon (1946–1953) recognized six *Canavalia* in Cuba. *Canavalia ensiformis* is used for forage, and its fruits and seeds are edible; *C. gladiata* seeds are edible, and its foliage is used for fodder.

Mabberley (1997) says young pods of *Canavalia* are edible, although unripe seeds are considered toxic, and that all species contain alkaloids. Burkill (1966), on the other hand, says that the Malays eat *C. rosea* flowers as a flavoring, and that they are also eaten in Malaysia. In that region, some people consider the young seeds a good “pease porridge, not uncommonly eaten.” Burkill even said that chemical studies showed no alkaloids or cyanogenic glycosides.

More recent studies of chemicals have established that, as Mabberley (1997) said, *Canavalia* contains several toxic chemicals. Among those are lectins, cyanides, complex proteins, and alkaloids (Bressani et al. 1987, Okolie and Ugochukwu 1989, Rosenthal and Berge 1989, Pérez et al. 1991, Abe 1993, Carlini and Udedibie 1997). Yet, other studies have confirmed what humans discovered thousands of years ago—processing of the seeds renders them edible (Apata 1994, Akpapunam and Sefa-Dedeh 1997, Vadivel 2001, Chel-Guerrero et al. 2002).

No records of *C. rosea* being used for food have been found in the New World. Only in Asia has it been recorded as food, although there are many records of other species being eaten in the New World.

There are numerous records of people feeding the foliage to livestock (e.g., Alain and Leon 1946–1953, Liogier 1974). In the Caribbean, the seeds are considered toxic and corrosive (Liogier 1974), but the leaves are used in medicines. Alain and Leon (1946–1953) noted, “*Dicen que ahuyenta las bibijaguas*” (they say it expels intestinal worms). In Hispaniola, the leaves are used in bitter tonics, and the roots are considered antiblennorrhagic. The plant is also used to treat asthma, although its toxic properties make that inadvisable (Liogier 1974).

### ***Canella*: Cinnamon Bark**

(From Latin *canna*, and Greek *kanna*, a reed, referring to the rolled bark used as a spice)

***Canella winterana*.** a. Flowering branch, b. Flower bud. c. Flower, side view. d. Flower from above, e. Flower longitudinally dissected, f. Floral diagram, g. Fruits. *Drawn by Priscilla Fawcett.* Correll and Correll 1982.

In the 1970s, I was visiting Fairchild Tropical Garden to consult its living and herbarium collection. A prominent Harvard botanist was also visiting. As we passed in the hall we began talking, and I noticed he had a branch in his hand. I asked about it, and he told me that it was *Canella winterana*, known in some areas as cinnamon bark. He informed me that the leaves had a wonderful taste, and I knew what was coming. He had the reputation of being a practical joker, and he had decided that I was to be his next victim.

Although I had not been in Florida long, I had heard about cinnamon bark. Fresh leaves are fiery, and they have been used to season foods throughout its range. Indeed, in Cuba they have the common name *pica-pica* (it bites, referring to the stinging taste). Although I had never tasted them, I knew they would be pungent. He offered me a leaf to taste, and I took an ample bite from its tip. Then, after waiting a few seconds, I commented with a deadpan expression, "It has a nice spicy taste." He said nothing, frowned, and stalked off to his work area without another word. Sometimes, knowing about plants allows us to save face, even if our lips and tongue are burning like crazy.

These trees grow from southern Florida to the Bahamas, Cuba, Jamaica, Puerto Rico, Virgin Islands, the Lesser Antilles from St. Martin and Barbuda to St. Lucia and Barbados. They are naturalized in Brazil and cultivated in Venezuela. The species had been known to Europeans since at least 1623 when it was called *Cinnamomum s[ive]*

*canella peruana* (Peruvian cinnamon or canella) by herbalist Gaspar Bauhin. Although Bauhin thought it came from Peru, Linnaeus listed it from Jamaica, Barbados, and “Carolina.” As usual, his biology was good, but his geography was bad. The “Carolina” he thought of as the place for the plants was actually extreme southern Florida.

Linnaeus first wrote about the plants in cultivation in his *Hortus Cliffortianus* published in 1738, where he called them simply *Winteranus*. Then in 1753, he decided to call them *Laurus winterana*, but noted, “*Flores ipse non vidi*” (I have not seen the flowers of these). If he had, he would not have put them with the genus *Laurus* and other members of the group later called Lauraceae in 1789 by Antoine Laurent de Jussieu (1784–1836). There are many differences between the flowers in Lauraceae and these plants. *Canella* does not have poricidal dehiscence in the anthers and their arrangement is not the 3-merous whorls of the Lauraceae. Instead, *Canella* has stamens that are connate by their filaments into a tube that almost or completely envelops the pistil. Those traits would have caused Linnaeus to put the genus elsewhere. However, where he may have put it is open to question. It was not realized how unique the plants were until 1759 when it was separated as the Winteranaceae. As a result of a technical problem, that name has been rejected and the species is now placed in the Canellaceae described by Martius in 1832.

Indeed, all of the people from Bauhin to Linnaeus who had studied these plants knew them only as trees with pungent spicy leaves. Bauhin called them a *Cinnamomum*, and Plukenet said it was a “Cassia,” which is a name used for another species of *Cinnamomum*. Sloane said that it was an *Arbor baccifera laurifolia aromatica* (tree with fleshy fruits and aromatic laurel-like leaves).

It was 1756 when Patrick Browne segregated out these plants as the genus *Canella*. In 1788, Joseph Gaertner put Linnaeus’s *Laurus winterana* into *Canella* to produce the modern name *C. winterana*.

From the beginning, *Canella* was known in Europe as a spice tree. Moreover, there was confusion between it and the true cinnamon sources of the Orient. Those plants are cinnamon (*Cinnamomum verum*=*C. zeylanicum*) and cassia (*C. aromaticum*=*C. cassia*). Because the part used is a rolled “stick” or “quill” of bark, kinds were distinguished largely by taste. Few could tell them apart by morphological traits. Yet, before modern times few inhabitants of the Old or New Worlds could afford to taste Asian cinnamon or cassia. For example, in 13th-century Britain, cinnamon sold for 10 shillings a pound and sugar went for 12 shillings. The prices remained proportional for centuries. Few rich people in the Americas could afford real cinnamon or cassia, and no poor people could use it. Rich and poor were forced to use the local equivalent, *Canella*. Olaf Swartz wrote in 1791: “This bark, together with the fruit of *Capsicum*, were formerly common ingredients in the food and drink of the Caribs [Caribs]” (Grimé 1976).

Most of the common names in the Americas also reflect spice usage. It is known as Bahama whitewood [bark] (English Antilles), *bois canelle* (cinnamon tree, Guadeloupe), *cancel* (variant of *canela*, Virgin Islands), *canela* (cinnamon, Puerto Rico), *canela blanca* (white cinnamon, Cuba), *canela de la tierra* (cinnamon of the land, Dominican Republic), *canelilla* (little cinnamon, Dominican Republic), *canella* (cinnamon, Puerto Rico, USA, English Antilles), *canella bark* (USA, Barbados), *canelle poivré* (cinnamon pepper, Haiti), *canellier bâtard* (bastard cinnamon tree, Guadeloupe), *canellier blanc* (white cinnamon tree, Guadeloupe), cilliment bush (variant of cinnamon bush, Virgin

Islands), cinnamon bark (Bahamas), cinnamon canella (USA), *corteza de winter falsa* (bark of false winter), *cúrbana* (maybe Taino, Cuba), false winter's bark, Jamaica cinnamon (Jamaica), pepper cinnamon (Virgin Islands, Dutch Antilles), whitewood bark (English Antilles), and wild cinnamon (Virgin Islands). Williams ([1837] 1962) wrote, "The bark is strongly aromatic, and flavored much like *Laurus cinnamon* [sic], but is more pungent."

Most use the bark to season food, but the leaves (Virgin Islands) and berries (Puerto Rico) are also used. Supposedly, the berries are hot like black pepper when gathered green and dried. Recently, my niece Stephanie Hicks Lindsay took a cooking course in New York City. In that course, she was taught to use "Mexican cinnamon," which they also called "canella." She raved about the superior flavor of this condiment, so I went looking for it in the local Tucson store. Perhaps because I shopped in a market that is mostly frequented by Hispanics, I found the "canella cinnamon" with no trouble. The checkout clerk, however, was not Hispanic. I had to tell her what it was so she could look up the price. My wife used the *Canella* instead of the Old World cinnamon on an apple cobbler. The taste is good, but I experienced an aftertaste that was bitter and unpleasant. Not everyone has that problem, and so the product is experiencing a revival in some areas.

A decoction of the bitter bark of *Canella* is used as a febrifuge and gargle to relieve sore throat in Brazil. It is also a febrifuge in Cuba where it is called *malambo* (Taino or African?). Similar uses include the infusion as a tonic (Puerto Rico), to relieve indigestion and fever in new mothers (Cuba), and to treat "female weakness" in the Bahamas (Roig 1945, Morton 1981). Not only is it a remedy for new mothers, but in Cuba it has been used as an abortifacient (Roig 1945).

The bark is macerated in alcohol or rum and rubbed on rheumatic and other pains in Cuba and Jamaica (Roig 1945). Leaf decoctions are also used in baths for rheumatism in the Bahamas, or the leaves and bark combined with other "bush" (medicinal plants) and made into a bush bath in the Virgin Islands (Petersen 1974, Morton 1981). The bark mixed with lime leaves and ginger helps stimulate appetite after illness in the Virgin Islands (Petersen 1974). Similarly, a leaf decoction is used to alleviate headache. The decoction of the wood is applied to the head or the chipped wood is smoked in a pipe in the Bahamas. Rum containing the bark is drunk for stomach pain in Jamaica (Morton 1981). The plant is considered so useful by some that it has been called *paratudo* (for everything, Brazil).

There are potent chemicals in the plant and they have been shown to have insecticidal activity (Udino 1994). Both leaves and stems are toxic to poultry. Those same poisons make it useful as a fish poison called *barbasco* [*marbasco*] (American variant of *verasco*, general common name for *Pterocaulon* and *Verbascum*, but also used for several fish poison plants, Puerto Rico). The bark formerly was exported to Europe and the United States for pharmaceutical use. Bark yields 0.75 to 1.25% volatile oil containing 1-*a*-pineol, cineole, caryophyllene, ~8% resin, and 8% manitol. There is also drimane sesquiterpene present (Kioy 1989, Kioy et al. 1989).

One point about the plants has bothered and intrigued me since I first learned about them in the 1970s. Catesby in 1731–1732 said that the pharmacies in London sold the remedy as "Winter's Bark." Linnaeus first called them *Winteranus* (*Hortus cliffortianus*

1738) and some of the common names contain the word “winter.” My confusion is this—does “winter” refer to a person or a season?

### **Canna**

(Greek *kanna*, a reed, Latin *canna*, a reed or cane; also “reed” in Akkadian, *qanu*, and Hebrew, *qane*)

#### ***Canna flaccida*** (flabby)

bandana-of-the-Everglades (Florida)

bird-shot (Florida, cf. Williams [1837] 1962); Indian-shot (Texas)

*sawakmalî:tî* (rattle’s contents, Mikasuki); *sáwko matihîta* (*skokv*, rattle, *em*, its, *vtehkv*, container, Creek)

Linnaeus began *Species Plantarum* with “*Classis I. Monandria. Monogynia.*” The first species on page 1 was *Canna indica*. He had three species, but there are now eight to ten known from the American tropics. Starch from *C. edulis* is considered easily digestible food for invalids, but most of the species are not eaten. Seeds may be viable for about 600 years, and they have been used as beads (Mabberley 1997).

The hard, black seeds were put inside a turtle shell or other item to make a rattle used in Seminole ceremonies (Sturtevant 1955). Judging from the common names “Indian-shot” and “bird-shot” the seeds have also been used as bullets in guns when no other material was available.

### ***Capparis*: Capers**

(From Greek *káppari* and Latin *capparis*; from Arabic *kabar*, head, because the buds resemble heads, cf. Marafioti 1970)

The first time I saw Florida caper fruits (*Capparis flexuosa*), I thought they looked like dentures. The pods are long and red, and embedded within are white seeds about the size and spacing of teeth. Admittedly, the red pod looks like a bad case of pyorrhea, but that was my first impression. I had read about and eaten the Old World capers, but the one in the coastal hammock was certainly different.

***Capparis.* *Capparis cynophallophora* .**

Above, flower, top view. Below, sterile branch. Drawn by

*P.N.Honychurch. Capparis flexuosa* .

a. Branch with flower buds, b. Leaf. c.

Flower, side view. d. Flower

longitudinally dissected, e. Fruit.

Drawn by *Priscilla Fawcett*. From

Correll and Correll 1982.

Linnaeus also realized that the American plants were different from those around the Mediterranean when he named both in 1753. He knew both species as living plants from cultivation, because he mentioned them in his *Hortus Cliffortianus* published in 1738. Moreover, he seems to have been impressed above all else by the long, slender, red fruits in the American plants. Certainly, those fruits were different from the short, fat pods of the European species. The Old World plants Linnaeus called *C. spinosa* because of their thorny nature. This and many other plants growing in the chapparal or *maccia* vegetation around the Mediterranean have armament of some type. The best-known American plants he called *C. cynophallophora*. This species name is one of the most famous examples of Linnaeus's uses of ribald names. *Capparis cynophallophora* means "the caper that bears a dog's penis." No other person or people in the world seemed to have noted that similarity until Linnaeus pointed it out. His seems to have been a uniquely vulgar mind.

The cultivated caper, *C. spinosa*, is commonly used as a food condiment in the Mediterranean countries. The unopened buds of these shrubby plants are used by people as diverse as the Saudis (*shafallah*), Greeks (*káppari*), Italians (*cappero*), Spanish (*alcaparra*), and Portuguese (*alcaparra*). Moreover, the usage has long been important in the cuisine of the region. Pickled, the buds add a unique flavor to particular dishes that are characteristic of southern Europe.

Whether the caper was spread from the Mediterranean through the Old World or introduced to there from the Orient is unresolved. The wide use of cognates for the Greek *káppari* argues for the first explanation, and many scholars support that view (Watt 1898, Hedrick 1919). In the major languages on the Indian subcontinent, names are related to the Greek phoneme. People in Bombay say *kabar*, and in widespread Hindi it is *kabra*. Across the Orient from east to west it is *kabra* (Bengal), *kabarra* (Punjab), *kabar* (West Pakistan), *kabarra* (Afghanistan), *kebir* (Persia), *kabár* (Syria), *kabar* (Arabic), and *kabarish* (Turkey) (Watt 1898). Those names apparently are not cognate to the Sanskrit *himsra*, or, if they are, they diverged from that language long ago.

The classical Eurasian literature had numerous records of the caper plants. For example, they were mentioned by authors like Antiphanes (4th century B.C.), Theophrastus (disciple of Plato and Aristotle, 372–287 B.C.), Zenon (ca. 260s–240s B.C.), Pliny (A.D. 23–79), Dioscorides (fl. A.D. 40–80), and Athenaeus of Naucratis (A.D. 170–230), author of *Deipnosophistai* (The Learned Banquet). Even the Greek prostitute Phryne (400–330 B.C.) was a dealer in capers (Hedrick 1919). According to Jean de la Ruelle (Ruellius), 1474–1537, capers were cultivated in France before 1536 (Hedrick 1919). Scholars seem to be divided over why the ancients compared them to goats (*kapra*). There is nothing much about the plants that resembles a goat, except perhaps the odor. Both the plants and the bovid have strong, fetid, and to Westerners at least, markedly unpleasant odors. In other words, they stink.

Yet, to the people of the Mediterranean, the goat was historically an essential part of daily and religious life. Goats provided food, wool, and skins that were important for people of all classes. In addition, the animals provided offerings to the deities in the form of sacrifice. Perhaps from their point of view, a comparison of a food additive to a goat was one of the greatest compliments that could have been paid.

Another critical consideration in using the plants for flavoring foods is that people from Portugal to India prefer strong-tasting food. Many Americans want bland food. As I used to tell my classes, if Americans can taste the food, they spit it out. That statement is an obvious exaggeration, but it is not that far from reality.

This cultural difference between these parts of the world is difficult to understand until one realizes that it has been only the past few decades that the chile has become popular among some groups in the United States. Even now, there are regions within the United States that consider *Capsicum* inedible unless it is the bell pepper, without capsaicin.

When the Europeans arrived in the New World, they found plants that they recognized as relatives to those of the Mediterranean *alcaparra*. These new plants were the American capers, but they were small trees, much larger than the small shrubs previously known. Moreover, the taste of these in foods was not the same as those from Spain and Portugal.

Indigenous people knew these American plants, and used them in seasoning, but they were not the important condiment that the genus was in the Old World. The Americans also used the plants in ways that were not familiar to Europeans. The larger plants allowed them to be used as wood for construction, tools, or even fuel (Little and Wadsworth 1964). Indigenous people also compared the fruits with others they knew and used names that showed that they had watched birds eating the fruits. Only the name *chile de perro* (dog [wild] chile, Chiapas) hints at a local use as a condiment.

Common names for these two species are not applied consistently, and there is considerable overlap in application. Both have similar or the same uses. An infusion or decoction of the leaves or roots is used as a diuretic and emmenagogue (Morton 1981). A decoction of the leaves is applied to various skin diseases, and the fruits are considered both sedative and antispasmodic. Not surprisingly, perhaps because of their long, slender, red fruits, both have been used to treat venereal diseases (Roig 1945). In the Cayman Islands, *C. cynophallophora* is called headache bush, suggesting another medical application.

Although Old World species of *Capparis* have been studied chemically more thoroughly, the New World species have received little attention. To date, it has been found that American *Capparis* have volatile oils, glucosinolates, and flavonoid aglycones (Kjaer and Schuster 1971, Gramosa et al. 1997, Pelotto et al. 1998).

Among the indigenous names for *C. cynophallophora* that do not seem to have been influenced by introduced languages are *arete* (Tabasco), *boxche'* (tree with black wood, Maya, Yucatan), *carbonero* (charcoal tree, Cuba), *ciguaraya* (bay tree, usually applied to a species of Meliaceae, Taino, Cuba), *endurece maiz* (it hardens corn, Nicaragua), *frijol* (bean, Dominican Republic), *frijolito* (little bean, Dominican Republic), *hoerihoei* (probably Arawak, Aruba, Bonaire, Curaçao), *paaloe die loora* (parrot tree, Papaimento, Aruba, Bonaire, Curaçao), *raaba* (Papaimento, Aruba, Bonaire, Curaçao), *stokki* (Papaimento, Aruba, Bonaire, Curaçao), and *zic* (Guatemala).

Some of the local names are simply based on the Old World word "caper." These include caper tree (British Antilles, USA) and Jamaica caper (USA). Others compare the plant uses to another Old World condiment, mustard (*Brassica nigra*). These include mustard tree (English Antilles, Dutch Antilles), *jeerba mostard* (herb mustard, Aruba, Bonaire, Curaçao), *mostacilla* (little mustard, Cuba), and simply Spanish for mustard (*mostaza*). These names are applied because the roots of the capers are ground and used much like mustard or horseradish (Little and Wadsworth 1964, Little et al. 1974).

Other names compare the trees to other plants. Some of these are black wattle and black willow (Bahamas, Jamaica). In these, the modifier "black" simply means "wild." A "wattle" in Australia, for example, is the genus *Acacia*. However, other people apply the name to any shrub or tree that could be used in this type of construction. "Wattle and daub" houses are a type used by people around the world where the "wattle" refers to the walls woven of various plant parts, and the "daub" is a mud covering to keep out hot and cold winds.

A number of other places make comparisons that are not obvious. Several describe the plants with the color black. These include *bois noir* (black bush, Guadeloupe), *burro* (Puerto Rico), *burro prieto* (Spanish Antilles), *palo de burro* (burro bush), and *palo de burro prieto* (black burro bush). The reason for calling them black is obscure. Some of the other names are complimentary and others are not. Among these are *bejuco Ingles* (English vine, Puerto Rico), *bois caca* (feces tree, Haiti), *bois d'argent* (silver bush, Haiti), *bois Sénégal* (Senegal bush, Haiti), man of war bush (Dutch Antilles), *oliba [olivo]* (olive, Dominican Republic), *palo diablo* (devil's bush, Cuba), *pois mabouye* (from Taino *maboya*, evil spirit bean, Puerto Rico), *sapo* (toad, Puerto Rico), wild orange (Bahamas), and zebrawood (USA).

Names that may be applied more uniquely to *C. flexuosa* include bay leaved caper (USA), flexible caper (Florida), *bois rave* (enraptured tree, Haiti), *bokanche* (*bo*, skin,

*kan*, viper, *che'*, tree, or tree that looks like a viper's skin, Maya, Yucatán), bottle wiss (wiss=vine, Tortola), *cansa caballo* (tires horses, Venezuela), *jos* (San Luis Potosí), *mimbre de monte* (wild *Chilopsis linearis*, called desert willow in English, Sinaloa), *naranjuelo* (little orange, Colombia), *palanguán* (big plate, Puerto Rico), *palo barba de indio* (Indian's beard bush, Cuba), *pan y agua* (bread and water, Venezuela), *potal* (anchor?, Guatemala), *tabarjeca* (Mayo), *tablelojeca* (Sinaloa), *thiuh* (Huastac, San Luis Potosí), *vela de muerto* (dead man's candle), and *xbayuamak* [*xbayumak*, *xpayumak*] (climber that destroys, Maya, Yucatán).

Both species are also used as a chewstick or toothbrush (Roig 1945, Morton 1981). The ends of small branches are chewed until they are frayed and only the fibers remain. These fibers are effectively used to clean the teeth and work at least as well as dental floss. This is not the only plant used in this way, and some also are known to contain fluorine. Maybe the American capers also fluorinate the teeth and help prevent dental caries. No one seems to have examined that possibility. However, no one knowing the scientific name *Capparis cynophallophora* would be able to use it without remembering Linnaeus's euphemism.

### Capraria: Goatweed

(From Latin *caprarius*, pertaining to goats, akin to Greek *capra*, goat)

*Capraria biflora*. Drawn by  
P.N.Honychurch.

The association with goats and these herbs came comparatively late to the scientific community. Two of the earlier Europeans who were familiar with the species had no real idea how unique the species was and compared it with *Lysimachia* (Plukenet in 1696), or with *Gratiola* (Commelin in 1701). Of those two, Commelin was by far the better

botanist. It fell to Paul Hermann in 1698 to coin the name *Capraria*. Presumably, that name was applied because goats grazed on the plants when no other farmyard animals would touch them. At least that is true today and the animals have not changed that much in the intervening centuries. The plants contain so many potent chemicals that even few insects graze on the foliage. The only butterfly capable of dealing with the poisonous compounds is the common buckeye (*Junonia coenia*). Although these Lepidoptera feed also on other members of the Veronicaceae, they must have cast-iron digestive systems if they feed on *Capraria* and *Scoparia*.

Linnaeus accepted Herman's suggestion, basing the genus on the Greek word *kapros* (goats), and gave us the modern name *Capraria biflora*. This is apparently a case where the scientific name led to the common name "goatweed." Often it is the common name or use that leads to the scientific name. Linnaeus knew the plants from Herman's report on the island of Curaçao, and also from cultivation in Uppsala, Sweden.

These plants are basically American, known from Bermuda, the Bahamas, Florida, the West Indies, southern Texas, and Mexico, to Peru and Brazil. *Capraria* also has been introduced into a few parts of the Old World tropics.

Many of the common names given to these plants revolve around their use as a tea. Among these are *chá da américa* (American tea, Brazil), *chá das Antilhas* (Antilles tea, Brazil), *chá de Lima* (Lima tea, Brazil), *chá de Marajó* (tea from Marajó, Brazil), *chá do Mexico* (Mexican tea, Brazil), *chá preto* (black tea, Brazil), *hierba [de] te* (tea herb, Panama), Jamaica tea, *tan-chi [tanchi, tantje]* (something to put in the mouth, Maya, Belize), *tantsji* (Aruba, Bonaire, Curaçao), *tasajo* (Chiapas), *té* (tea), *te de las Antillas* (Antilles tea), *té de monte* (wild tea), *té de salud* (health tea), *té de Santa María* (Saint Mary's tea), *té del país* (country tea), *té nacional* (national tea), *té silvestre* (wild tea), *thé d'Amérique* (American tea, French Antilles), *thé de Antilles* (Antilles tea, French Antilles), *thé de Guadeloupe* (Guadeloupe tea), *thé de sante* (saint's tea, French Antilles), *thé des Anglais* (English tea, French Antilles), *thé du pays [du the pays, dite payi]* (country tea, French Antilles), *thé muraille* (mulberry tea, French Antilles), *thé pays* (country tea, French Antilles), *thé suisse* (Swiss tea, French Antilles), West Indian tea, and tea (Dutch Antilles).

First and foremost, this is a substitute beverage for ordinary tea (*Camellia sinensis*) from Belize and the Bahamas south to Venezuela. In addition, this "tea" is an almost universal panacea in some places, or at least considered a highly effective tonic. The beverage is used against colds, colic, coughs, diabetes, diarrhea, flatulence, fevers, gonorrhea, hemorrhoids, indigestion especially in pregnant women, influenza, kidney or bladder problems, leukorrhea, measles, menstrual cramps in young girls, *pasmo* (blood stagnation or congestion), sore eyes, rheumatic pains, and tiredness (Morton 1981, Austin and Bourne 1992, Mors et al. 2000). The decoction is astringent, tonic, and stops vomiting. Juice drops also are put in the ears to combat earache. Not only is the decoction used as a tea, but also as bush baths. The common name that reflects this wide medicinal usage is *pericón* (useful for everything, or heal-all). The Bahamaian names stow wort and stow-weed probably mean essentially the same. An archaic meaning of "stow" is to "stop."

Several uses are associated with childbirth. A decoction combined with *Heliotropium angiospermum* is given to all week-old babies when they are "changing skin" in Curaçao (Morton 1981). In the Bahamas, it is given to expectant mothers to expedite labor. In

Trinidad, it is drunk after childbirth. The same mixture is used to alleviate painful menstruation. In at least Yucatan and Cuba, it is a vaginal douche and likely effective against *Candida* infections.

Some of the common names reflect the medicinal uses without adding the word for tea. Among these names are earache bush, grannybush, worry bush, *viuda* (widow), *pasmo-wa-xi-uil* [*pasmoxiu*] (herb in the shape of a tortilla [*wah*, tortilla, *xi-uil-xiw*, herb] used to treat *pasmo*, Maya, Belize, Yucatan). Sometimes that is simply shortened to *pasmo*. Probably the name *chokuilxiw* [*chakuil-xiu*, *chocuilxiu*] (herb of the rat god, Maya, Yucatan) also reflects medicinal uses.

Other common names reflect a more frequent and utilitarian use as a broom. Most obvious of these are *escoba* (broom) and *escobilla* (little broom). However, it is likely that *claudiosa*, *claviosa*, *esclaviosa*, and *escabiosa* are mispronunciations of those names or misunderstandings by people who recorded them. These names refer to such disparate things (a person named Caludio, a heart, and the plant called “scabios” in English) that they must be errors of one kind or another. *Feregosa* probably belongs in this list, too. Surely, *cola de gallo* (rooster tail, Panama) is also associated with use as a broom.

In Oaxaca, Mexico, the plants are called *lengua de gallina* (chicken tongue). That must be an allusion to the long slender leaves as there is nothing else about the herbs that resembles a tongue. In Veracruz, it is *peludillo* (little hairy one), an inappropriate name because the plants are essentially glabrous. Could this be like the English expression: “It will grow hair on your chest”?

Some names either misidentify the plants or have a nomenclature system different from that used by the scientific community. These include *malvavisco* (usually confined to *Malvaviscus*, of the Malvaceae, Oaxaca) and *verbena* (verbena, Verbenaceae). Names given by Morton (1981) that have not been located elsewhere are *magüiro*, *majuito*, and *makjuito*. These resemble indigenous words but their provenance and meaning have not been determined.

Water extracts of dried leaves have hypoglycemic activity in mice (Pérez et al. 1984), and root extracts are cytotoxic against certain kinds of cancer (Nascimento et al. 1985). The antibiotic alkaloid biflorine was isolated from roots (Gonçalves et al. 1953, 1958). In large doses, biflorine causes dizziness, intoxication, and stupification. One study showed that leaves from goatweed were a central nervous system depressant. That depression probably leads people in the Netherland Antilles to chew the plant as a tobacco substitute.

### ***Capsicum*: Bird Peppers**

(From Greek, *kapto*, to bite, or from Latin, *capsa*, a box, a reference to the fruit's shape)

***Capsicum annuum* var. *glabriusculum*.** a. Branch of flowering and fruiting plant, b. Flower, back view, c. Flower, front view, d. Flower, longitudinally dissected, e. Floral diagram, f. Fruit. *Drawn by Priscilla Fawcett.* Correll and Correll 1982.

From Florida south into the tropics are herbs about 1.5 m (4.9 feet) tall that have small, inconspicuous, white flowers. Fruits smaller than the end of your little finger follow and then turn red when ripe. Birds love these little fruits and greedily defend the area where the bushes grow. Humans, too, love the fruits and compete with the birds for the harvest. This competition has been going on since there were humans and birds in the Americas. English-speaking people usually call the fruits bird peppers (Florida to Belize). Several others associate them with birds in their common names, including some that are simple translations, and others that give different ideas. For example, Haitians say *piment z'oiseaux* [*piment zouézeau*, *piment zouézo*] (bird pepper), while it is *ají pajarito* (little bird pepper) to Colombians, and the Huastec of Mexico say the same with *ts'itsin its*. However, the Huastec have noticed another aspect of this bird/plant association and also call them *taa' ts'itsin* (bird excrement). Birds do “plant” peppers regularly.

These herbs are *Capsicum annuum* (annual). Some call them *C. annuum* var. *aviculare*, and others use *C. annuum* var. *glabriusculum* (completely without hair). The correct name is the second, although it is too bad we cannot retain the one that nicely translates the common name—*aviculare*=of birds. Linnaeus called it *Capsicum* in 1753. Surely, this is another of Linnaeus's dual meaning genera intended to cause us to wonder, or perhaps, even to convey both meanings (Austin 1993).

The first Spanish in the Caribbean asked the natives what they called those blazingly hot little fruits that they added to their food. The Taino people of Cuba, related to the Arawaks of northern South America, replied that they were *ají*. This word, variously

written as *axí*, *ajé*, *agí*, and *así*, came to mean *Capsicum* from Cuba to Peru. The Dominican Caribs still call them *áthi*. Their Central American Island Carib relatives say *áti*, Arawaks say *háthi*, and Guajiro *hasi* (Taylor 1977). The Garífuna of Nicaragua say *áti*. Mexican people using similar if not cognate names to *ají* are the Mayan who say *ik* [*ik*, *ic*], the Huastec with *its* [*itz*], and perhaps *corí* [*coriquí*] (Tarahumara, Chihuahua), *ng-i* [*júguñi*] (Otomí, Hidalgo), *pin* [*stac'apin*, *lactzu-pi'n*] (Totonac, Puebla), *pitzaj* (San Luis Potosí), and *ya'a* (Mixtec, Oaxaca). More distant, but still perhaps related, are *uchu* (Quechua, Peru) and *huayca* (Aymara, Peru).

Many other people have names for the bird peppers that apparently mean simply *Capsicum*. These include *chicnigüi* (Chiapas), *có'cori* [*cócorit*, *cí'ocori*] (Mayo, Sonora), *conguito* (Colombia), *tichushi* (Oaxaca), *gapuchín* (Veracruz), *guina* [*guiña*, *quiña*] (Zapotec, Oaxaca), *jonguñi* (Otomí, Hidalgo), and *jonnigüi* [*jonnihui*] (Zoque, Chiapas). The Tarahumara recognize three varieties, *wum pei*, *wum ganario*, and *wum ka?* (Chihuahua). The Jicaque of Honduras say *cela* (Lentz 1986).

Throughout the Greater Antilles, people still use the basic Taino word for the fruits, although now it is Spanish. Variations include *ají bobito* (crazy little chile, Hispaniola), *ají caballero* (gentleman pepper, Puerto Rico), *ají caribe* (Carib chile, Hispaniola), *ají chirel* (insipid chile, Colombia, Venezuela), *ají chivato* (goat pepper, Colombia), *ají guaguao* [*huarahua*] (wild chile, Taino, Cuba), *ají montesino* (little wild chile, Hispaniola), *ají picante* (spicy pepper, Puerto Rico), and *ají titi* (monkey chile, Hispaniola).

The name *ají* was carried by the Spanish from the Caribbean to Peru and surrounding countries, where it was adopted into the locally spoken Creole. However, this did not occur in Mexico and other parts of North America, or in Brazil.

The dominant people in Mexico were the Aztecs. In their Náhuatl language, they called these spicy fruits *chilli*. Variations on that in Spanish became *chile* or *chil* from California through Arizona to Texas south to Venezuela. There are dozens of varieties and variations of chiles, but the one called bird pepper was the *chiltecpin* (literally “flea pepper,” because it bites, Náhuatl). This too has variants including *chillipiquin*, *chiltepín*, or *chile piquín* (Sonora, Hidalgo, Puebla), *chiltepe*, *tepín*, and *pequin* (Mexico to Costa Rica). The biting aspect of the chile is also reflected in the names *chile diente de tlacuache* (opossum’s tooth chile, Tamaulipas), *cuachile* [*guachile*] and *chile cuachile* (chile that bites, Náhuatl, Oaxaca), and *tempechile* [*tenpechile*] (*tentli*, lips, apparently an allusion to the burning of the lips, Náhuatl, Chiapas).

In addition, chile has other modifiers that are applied, either locally or to note particular variants and/or uses. Among these are *chile amash* (papery? chile, Tabasco), *chile bravo* (wild pepper), *chile de monte* (wild pepper, Sonora, Yucatán), *chile de zope* (vulture’s pepper), *chile quimiche* (*quimchin*, rat, Náhuatl, Oaxaca), *chile siete caldos* (chile enough for six stews, Chiapas), and *chilillo* (little chile, Yucatan).

Other people have variations on the biting taste of these hot little fruits. In Yucatán, the Maya call bird peppers *max'ik* [*max*, *a'h'max-ik*] (*max*, bumblebee, plus chile, or chile that stings like a bee). In Costa Rica, they say *quiebra-muelas*, a chile so hot it is a “tooth breaker.” Colombians simply say *pimiento morrón* (pepper that hits). In French areas, it is *piment caribe* (Carib chile, a reference to a formerly cannibalistic tribe, Dominica), or *piment enragé* (mad chile, French Guiana).

Some make other comparisons. As examples, they are little chiles to the Seri of Sonora (*coquée-quizil [quishil]*). The Huastec of San Luis Potosí also call them little chile, *tsakam its [tzacam-its, chakam ich]*, but they recognize an almost indistinguishable type as *ts'aah its* (vine chile). The Tohono O'odham (Papago) of Arizona call all chiles *ko'okol [o'olas]* (from *s-ko'ok*, to hurt), but their relatives, the Akimel O'odham (Pima), call bird chiles *o'olas ko'okol* (spherical chile). English speakers have variants too, with goat pepper, heart-pea, heartseeds, red pepper, and wild pepper. The southeastern people had no name for these new plants, and said simply *hishi homi humma* (pungent red leaf, Choctaw).

Brazilians and other South Americans also use variations of the original word that Columbus called them in his journal—*pimiento*. This name is akin to Portuguese *pimento* and French *piment*. All are derived from Medieval Latin *pimenta*, a spiced drink, hence also spice or pepper. The same Latin *pimenta* meant drugs or juice of plants, and color.

We use the word “pimento” in English, but now usually to apply to one bland cultivar. In addition to those already listed are *pimenta* (Brazil), *pimientones* (Colombia), and *pepre* (pepper, Suriname). Brazilians have a variety like one of the longer cultivars of *chiltepin*, but they call it *pimenta malagueta*. The word *malagueta* may have come from Málaga, Spain, which was a center of Portuguese trade in spice (Ferreira ca. 1978). Or it may have come from Melle, in Niger, as Fuchs (1542) used the name *melegetae*, which appeared in European literature by A.D. 1214. *Melegetae* originally was *Aframomum melegueta* (Zingiberaceae), which was used as a substitute for black pepper (*Piper nigrum*) before the New World was discovered.

Our word “pepper” had a different origin. That came into English by the 1100s and was *peper* in Middle English and *pipor* in Old English. All three are cognate with German *Pfeffer*, Dutch *peber*, Norwegian *pipar*, and Swedish *peppar*. They are based on Latin *piper* and Greek *peperi* and were adopted from those Mediterranean languages before the 4th century A.D.

When Cristobal Colón (Christopher Columbus) first arrived in the New World, he found the natives of the Caribbean eating deliciously spicy condiments with their food. Since the most valuable resource of the time was pepper, Columbus was delighted. He wanted gold, but surely he could get plenty of that with these fiery fruits. He wrote: “Finally, to compress into a few words the entire summary of my voyage and speedy return, and of the advantages derivable therefrom, I promise, that with a little assistance afforded me by our most invincible sovereigns, I will procure them as much gold as they need, as great a quantity of spices.”

Columbus promised gold and spices in equal quantities, but most historians do not even mention the plants. In fact, spices provided greater wealth to Europeans than those metals. It is difficult to believe the value Old World people put on pepper (*P. nigrum*). For example, in A.D. 410, Alaric the Goth captured Rome and demanded as tribute 30,000 pounds of silver, 5000 pounds of gold, and 3000 pounds of pepper (Howard 1996). In the Middle Ages rents, dowries, and taxes sometimes were paid with peppers. Landlords wanted rental in peppercorns rather than money. Trade in spices, predominantly pepper, made the famous centers of commerce of Alexandria, Genoa, and Venice the richest parts of Europe up until the 1500s. These cities had trade monopolies with the Arabic merchants and then sold the produce at inflated prices to the other Europeans (Rosengarten 1969).

It was largely an attempt to break that domination by these centers that initiated exploration of new routes to the tropics to obtain spices. Expeditions of both Columbus and Vasco de Gama were prompted by Portugal and Spain's desire to find cheaper spices. Indeed, the royalty expected to earn more from the spice trade than from gold and silver. Columbus found what he thought was the "orient," but brought home a red spice called *ají* and not the black pepper that Europe knew. It took time for merchants to realize how useful that condiment was, and they were still hungry for the familiar black pepper. Vasco de Gama left Portugal searching for a sea route to the spice-producing Malabar Coast of India in 1498. His success broke the trade monopoly and eventually led to the economic decline of Alexandria, Genoa, and Venice (Rosengarten 1969).

Although black pepper is still the most important spice in the world, chiles run a close second. Chiles are even better because they provide benefits unachievable with black pepper. Chiles are healthy food and provide chemicals needed by the human body that are not in black pepper. Chiles have many compounds besides the hot stuff (capsaicin), including vitamins A and C. In addition to capsaicin, compounds in chiles include solanidine, solanine, solasodine, and scopoletin. Duke and duCellier (1993) list 63 chemicals in *Capsicum* suspected of having cancer-preventative or antitumor activity.

All those chemicals make it easier to understand why people have used chiles in remedies to treat so many maladies, including asthma, backache, cancers, cough, gonorrhea, hemorrhoids, liver congestion, rheumatism, sore throat, swollen feet, toothache, tumors, and varicose veins. The Aztecs used chiles to punish children (Ross 1978), and others have used them as a calmant and to stop thumb-sucking and nail-biting. In addition, there is evidence that they stabilize blood pressure and reduce excessive bleeding. Although it is difficult to believe the mothers could stand the cure, some indigenous people in the southwestern United States have used chiles to wean infants from breast-feeding.

So, the next time you bite into a chile-laced dish, and the tears start streaming down your cheeks, remember that you are eating healthy food. As Mexicans say, "*Chiles dan sabor a la comida*" (Chiles give taste to food).

### *Cardamine*

(From the Greek *kardamis*, a kind of cress)

*billeri* (bilious, Italian)

*biolair ghriagain* (*biolair*, cress, *ghriagain*, deer, Gaelic)

*cardamine* (from Greek *kardamis*, or the carding tool for wool, French)

cuckoo flower

*karse* (cress, Norwegian); *Schaumkress* (foam cress, German)

*mastuerzo de prado* (meadow mustard, Spanish)

*Cardamine concatenata* (with a chain)

cutleaf toothcup

bittercress (“cress,” *Lepidium sativum*, is either derived from a Old High German *chresan*, to creep or creeper, or from Latin *crescere*, to grow)  
*cardamine* (French)

Linnaeus included six species in *Cardamine* in 1754. All of them were from the Old World. Now there are 200 temperate species known, with 31 of them native to Europe (Mabberley 1997). Several of the European plants have been put in *Nasturtium*, and that suggests that they may have been eaten.

Hedrick (1919) listed eight species of *Cardamine* used from the Straits of Magellen to New Caledonia, so the comment by Fernald et al. (1958) that species, other than the two they listed, “doubtless have similar qualities,” is surely correct. Most who comment on the genus suggest that it has “just the taste of the English water-cress” (Hedrick 1919). The comparison in the name to “cress” records that long-standing impression.

The Iroquois used *C. concatenata* as food, eaten raw or with salt and boiled (Moerman 1998). Several other species are known to have been used by a variety of indigenous people as food or flavoring in food (Moerman 1998).

Additionally, this species was used as a medicine. The Iroquois mashed the roots and applied them to the head to relieve headaches, to treat colds, to stimulate the appetite and regulate the stomach, to alleviate heart problems, and to treat injuries (Moerman 1998). The herbs were also considered somewhat hallucinogenic, and were used in divination, as a hunting medicine, and as a “love medicine” (Moerman 1998).

### ***Cardiospermum*: Balloon Vine**

(From Greek *kardia*, heart, and *sperma*, a seed; refers to the shape of the seed or to the heart-shaped spot on the seed)

In southern Florida, you may find a bank of vines covering much of the other plants on a fence, or sprawling over shrubs on the edge of a disturbed site. These vines are mostly in Monroe and Miami-Dade Counties, but they may occur as far north as Seminole and Polk Counties. The fruits are eye-catching because they look like little balloons—hence the name balloon vine used from Florida and the Bahamas south to at least Panama. The plants are probably *Cardiospermum halicacabum*, although they might be *C. microcarpum*; the former is the more common of the two.

The flowers are small and greenish, but the foliage and fruits are a magnet for three butterfly species. These are the amethyst hairstreak (*Chlorostrymon maesites*), the silver-banded hairstreak (*Chlorostrymon simaethis*), and the Miami blue (*Hemiargus thomasi*). The amethyst hairstreak also uses a number of other plants to feed its larvae, but the silver-banded hair-streak prefers to put its eggs on the *Cardiospermum*. If you open the fruits, you find the caterpillars inside—or at least the frass from where they have been feeding. Since the plants are comparatively rare, these butterflies too are uncommon. In the early 1970s, it was hard to find a fruit without some sign of the silver-banded hairstreak having used it.

These plants occur around the world. They have attracted the attention of people in many areas and even made it into cultivation for the ornamental “fern-like” foliage and

swollen seed pods. Most scholars think that *C. halicacabum* is native to the American tropics, including the southern United States. This may be one of the many medicinal plants that were carried around the world by the early Europeans. However, equally probable is that it has been spread around the world by nonhuman means. At least Smith (1985) was of the opinion that it is easily dispersed and probably indigenous throughout its range.

*Cardiospermum halicacabum* is found in the United States from Florida to Texas, and north to Kansas and Delaware. Small (1933) thought that it had been introduced from tropical America, and that is a possibility. Others have treated it as native, at least to Florida, and we make that assumption here. Outside the United States, the species is found throughout much of Mexico, Mesoamerica, the Caribbean, and in South America to Peru and Argentina. It is cultivated in Brazil.

Balloon vine is also widespread in the Old World. Indeed, in 1753 Linnaeus knew it from cultivation in Europe and from the wild only in Sri Lanka. The species name *halicacabum* was taken from some plant the Greeks called *halikakabos*. That was also a plant Plinius called *vesicaria*. Linnaeus adapted the specific epithet from the classical usage.

 Correll 1982.

The species has been in India for so long that it has the Sanskrit names *indravalli* (Indra's vine; Indra is the Hindu god of thunder and storms), *Jyautishmati*, and *kāravi*. Having a name in an extinct language is taken by most people as good evidence of nativity to a particular region, and balloon vine qualifies. Moreover, there are common names in Bengali, Gujarati, Hindi, Kannada, Malayalam, Marathi, Tamil, and Telugu. The fact that these names all differ from one another, and from American names, further suggests a pre-Columbian history in the Indian region.

American common names, in addition to balloon vine, are varied. Many of the other names also refer to the fruits, including heartpea (USA, Jamaica), heart-seed (USA), love-in-a-puff (horticulture), and *bonnet carvé* (square hat, Hispaniola). A variant is a bit more vulgar in Mexico where they are called *huevo de gato* (cat eggs [testicles], Durango). Apparently, the shape of the fruits also led to names like *bombilla* (electric lightbulb, Puerto Rico), *bombilla menor* (little electric lightbulb, Puerto Rico), *farolito* (little lantern, Cuba, Puerto Rico, Panama, Colombia), and *farolito de la Virgen* (the Virgin's little lantern, Venezuela).

Other names refer to other aspects. In India, and perhaps other areas, the plant is known as the blister creeper, a reference to irritating chemicals it contains. Trinidadians call it bich grass or *zeb bich* ("bich" is an intestinal malady). Mexican goats eat the twiners, and people call them *hierba de chivato* (goat's herb, Tamaulipas). There are even comparisons to other plants. To some the finely lobed and toothed leaves resemble parsley (*Petroselinum crispum*), with names like *bâtard persil* (false parsley, Dominica) or *persil bâtard* (Hispaniola). Other people think the vines look more like the sweet pea (*Lathyrus odoratus*), and call them *guisante maravila* (marvelous sweet pea, Puerto Rico) or *pois [de] merveille* (marvelous sweet pea, Hispaniola). They are also called wild supple jack (Jamaica) and winter cherry (USA, India). Some people simply refer to the fact that the plants are cultivated and say garden wine (wine=vine, Turks and Caicos).

There are also names that refer to medical uses such as sprainbush wine (wine=vine, Dutch Antilles). Several names make obscure references. These uncertain names include *muditos* (little changling, Oaxaca), *revienta caballos* (horse breaker, Cuba), and *toffe-toffe* (a *touffe* is a clump of grass, Hispaniola). Presumably, the first two allude to medicinal uses. Since the plants are considered laxative, the name *revienta caballos* may be an allusion to that. Perhaps the Hispaniolan name alludes to the massed clusters in which the plants grow. Biloxi in Louisiana said *po'poxyti* (*popoxi+tyi*, swelling medicine) and used the root in a remedy for dropsy (Dorsey and Swanton 1912).

Americans use the plants in a variety of ways. The most prominent medicinal treatment is for kidney problems. In Mexico, Cuba, Hispaniola, and the Turks and Caicos Islands the plants are considered diuretic (Standley 1920–1926, Roig 1945, Liogier 1974, Morton 1977, Ayensu 1981). In Mexico the roots are used, in Cuba the leaves, and in the Turks and Caicos the seeds. Each area has its own variant of medicinal preparations, including decoctions of roots and leaves. Others use the seeds, which are parched, ground like coffee, and boiled (Ayensu 1981). The preparation in each area, however, is prescribed for swelling of the legs and feet associated with kidney trouble. This same decoction is used to treat rheumatism and arthritis in Argentina.

The same or similar preparations are given in Mexico as sudorifics, emetics, purgatives, diaphoretics, and rubifacients in rheum (Standley 1920–1926). Cubans also use it as a sudorific (Roig 1945). In Hispaniola, the same basic decoction, either boiled or not, is also considered a refreshing drink (Liogier 1974). Similarly, in Dominica, the leaves are crushed in water by Caribs to make a refreshing and cooling drink (Hodge and Taylor 1957). People in Hispaniola also use the leaves and stems in emollient poultices for abscesses and sores. In Trinidad, leaves are used as an infusion for “bich” (lower intestine disease) and indigestion (Morton 1981).

According to Parrotta (2001), extracts from the plant have sedative effects on the central nervous system, and act as an analgesic, anti-inflammatory, vasodepressant, and antispasmodic. The plant contains at least saponins that would make it effective as a diuretic. The same saponins would be responsible for a slimy consistency that would be effective in poultices. A related species has a sulfur-containing cyanogenic glucoside (Hübel and Nahrstedt 1979). Probably *C. halicacabum* has the same or similar glucosides. In addition to medicinal uses, the saponin foams when the plants are rubbed in water, and the solution has been used as a soap substitute (Morton 1981). Caution is indicated because the chemicals in the plant irritate the skin in some people.

People also have uses for the plants other than medicinal. In the coastal Carolinas, the young foliage is cooked and eaten as a potherb (Morton 1968b). That usage may have been introduced by Africans because it is known in Africa and Asia. In Colombia, the tough stems are used mostly as a ready-made twine to tie up rustic constructions. In many places, the seeds are used in necklaces and other novelties. In some parts of Brazil, the plants are cultivated for the seeds that are made into small bands worn by men. They believe that these bands will ward off snakebite (Mabberley 1997). Outside the Americas some also believe that the plants are aphrodisiac.

The plant was first mentioned by German herbalist Leonard Fuchs (1542). He noted it as a novelty in his country that none of the ancient authorities apparently knew. Soon afterward, another European herbalist deduced that the plants should be used medicinally for heart disease. That conclusion was not based on that use elsewhere, but rather on the similarity of the shape of the fruit to the heart.

Fuchs (1542) also recorded common names that are no longer used. He put the plants immediately after what he called *Halicacabum vulgare* (now *Physalis alkakengi*) and said that the new plant was *H. peregrinus* because it had recently “traveled” to Germany. The English of his time called the plants “blacke winter cherie.” That surely gave rise to the modern name “winter cherry.” In German it was *welsch Schlutten* (foreign ground cherry), and in Dutch *roomsche criecken van over zee* (Roman [Catholic] cherry from across the sea). In French it was *halicacabon estrange* (foreign *halicacabum*), and in

Italian *halicacabo salvatico* (wild *halicacabum*). The Spanish called it *yerba mora desta suerte estangera* (foreign bramble herb). Fuchs gave the plant no medicinal value in spite of writing a book on that topic, but he suggested that this new plant would be “suitable for planting on arbors.” That statement presaged history.

### *Carphephorus*

(Greek *carpho*, dried up, withered, *karphe*, hay, *phorus*, bearing)

*Carphephorus odoratissima*. From Britton and Brown 1898.

*Carphephorus corymbosus* (having flowers in flat-topped clusters)  
 coastal plain chaff-head [coastalplain chaffhead]  
 paint-brush [paintbrush] (given to the instrument with bristles to apply paint by 1837; later to plants)

*Carphephorus odoratissima* (very fragrant)  
 deer[’s] tongue (“deer” from Old English *dior*; entomologically related to *dier* in Dutch and *Tier* in German, both with the more general meaning of “animal”); combined with tongue to allude to leaf shape; in use by 1883, southeastern USA)

dog tongue (southeastern USA); hound’s tongue (comparison of the leaves with *Cynoglossum*, which see, southeastern USA)

vanilla leaf [vanillaleaf] (apparently in use after 1856, Florida); vanilla plant (“vanilla” came into English by 1662 from Spanish *vainilla*, diminutive of *vaina*, sheath, referring to the pods of the orchid *Vanilla planifolia*; the first record of it found associated with this Asteraceous herb is by Asa Gray in his *Manual of Botany* from 1856; he wrote of the “Vanilla-plant... Leaves exhaling the odor of Vanilla when bruised,” southeastern USA)

In 1816, French specialist in the family Asteraceae, Alexandre-Henri Gabriel Comte de Cassini (1781–1832), created the genus *Carphephorus* for an American plant. It is now known that the genus contains four species, all endemic to the southeastern United States (Correa and Wilbur 1969, King and Robinson 1987).

Murphee (1965) found residents of the Florida Panhandle putting these herbs in pillows to relieve asthma. *Carphephorus odoratissima* leaves contain coumarin and have been used as a flavoring agent, particularly in smoking tobacco, perfumes, and to imitate vanilla extract (Small 1933, Christensen 1946, Lewis and Elvin-Lewis 1977, Hocking 1997). It also has been used as a aromatic tonic, diaphoretic, stimulant, and diuretic (Hocking 1997). *Carphephorus corymbosus* is a urinary antiseptic and is sold under the proprietary name Rasapen.

### Carpinus

(The classical Latin name of the hornbeam, said to be from *carpentum*, a Roman horse-drawn vehicle with wheels made from its hard wood; akin to Akkadian *karru*, mountain range, and Hebrew *pinna*, pinnacle)

*agn-bøk* (*agn*, husk, *bøk*, beech, Norwegian)

***Carpinus caroliniana*.** From Sargent 1905.

*carpino* (from *carpinus*, Italian); *charme* (French)  
*leamhan-bog* (marsh elmwood, Gaelic)

***Carpinus caroliniana*** (of Carolina)

*amerikanische Weib-Buche* (American female-beech, German)

*amerikansk avenbok* (American night-beech, Canada)

blue-beech [bluebeech]

*bois de fer* (ironwood, Quebec)

broom-wood [broomwood] (presumable the branches were used to make brooms)

*carpino* [*carpe*] *americano* (American *Carpinus*, Guatemala, Honduras)

*charme [d'Amerique]* ([American] hornbeam, Quebec); *charme de Caroline* (Carolina hornbeam, French)

*Hainbuche* (thicket beech, German)

[American, hop, hophornbeam] hornbeam (“horn-beam,” the name of a European species from the 1570s or before, because of its hard, tough, close-grained wood; formerly called “hard-beam,” USA, Canada)

*icimilapi* (Koasati)

ironwood (name given, often locally, to various trees with extremely hard wood; dating from at least as early as the 1650s)

*ittopankachi* (*itto*, tree, *panayka*, curled, *chi*, repetitive suffix; probably akin to “muscle-tree,” Alabama); *ittosankachi* (*itto*, tree, *sanayka*, twisted, *chi*, repetitive suffix, Alabama)

lean-tree [leantree]; *otantahrteweh* [*o-tan-tahr-te-weh*] (lean tree, Iroquoian)

*lechillo* (little bed, Texas, Michoacán)

*mora de la sierra* (mountain mulberry, Sinaloa)

muscle-tree [musclewood] (named for the undulations on the trunk that resemble muscles)

*palo barranco* (ravine tree, Michoacán)

*palo liso* (smooth tree, Mexico)

smoothbark ironwood

*tzutcamay* (Zoque, Chiapas)

water-beech

Linnaeus created *Carpinus* in 1753, including two species, *C. betulus* and *C. ostrya*. In an unusual confusion, he attributed both to the Americas and to Europe. *Carpinus betulus* is native to Europe and extends from southern Norway south into the Mediterranean mountains. The plants he called *C. ostrya* ultimately became known as *Ostrya virginiana* in the Americas. It was not until 1788 when Thomas Walter gave the American *Carpinus* its name in his *Flora Caroliniana*.

Europeans were well acquainted with the useful wood of *Carpinus*, and they quickly understood the benefit of having a related species in the Americas (Edlin and Mitchell 1985). We now know of 26 northern temperate species, with 2 in Europe (Furlow 1990, Mabberley 1997).

Logs were used as the main supporting post for the ridge pole of Ojibwa lodges (King 1984). Colonial settlers in America used *Carpinus* to make bowls and dishes because it rarely split or cracked. Hornbeam has a thick, nearly white sapwood and a heartwood, which is pale yellow to tan. It has no characteristic odor or taste. The wood is hard and heavy, with a dry specific gravity of 0.58 (Miller and Wiedenhoeft 2000). The wood is difficult to work but has been used to make tool handles, levers, parts for farm machinery, and fuel wood. The wood is said to be an irritant to some people (Miller and Wiedenhoeft 2000), although it is not listed by Hardin and Arena (1974), Lampe and McCann (1985), Blackwell (1990), or Turner and Szczawinski (1991).

These trees were used through much of the Eastern Deciduous Forest. Among the people making medicines of them are the Delaware and Iroquois of New England, and the Cherokee of the Carolinas (Moerman 1998). The most widespread use was a mixture

of the bark and other plants to treat diarrhea (Hamel and Chiltoskey 1975, Moerman 1998). Other uses for the tree included treatment of urinary problems, women's diseases, "general debility," itch, and consumption, and to facilitate childbirth.

### *Carya*

(From Greek *karya*, a walnut tree)

*anaskomins* (Powhatan, Virginia); *osámener* (yellow nuts, Carolina Algonquins); *msim* (the nuts, Delaware)

*asonòka* (hickory nuts, Onondaga); *waneʔi* [*waneʔ-i*] (Cherokee)

hickory (shortened from *pohickery*, *pakahochory*, *powcohicoria*, or *pawcohiccora*; originally meaning the milk-like emulsion of the nuts; from *pakāhikāré*, it is pounded [brayed], Virginia Algonquian; first used by Strachey in 1612)

***Carya.*** *Carya alba* (upper left). From Sargent 1905. *Carya aquatica* (right), a. Branch with fruits, b. Fruits, c. Fruit, side view. Drawn by Vivian Frazier. From Correll and Correll 1972. *Carya glabra* (left middle). From Sargent 1905. *Carya illinoiensis* (lower left). From Sargent 1905.

*kapko* [*kapun, yuhe*] (nuts of shagbark or *C. ovata*, Choctaw)

*ocá* (Koasati); *o'ce* (Muskogee); *ocha* (Alabama); *oksak* [*uksak*] (the nuts, Choctaw); *osak* [*oksak*] (the nuts, Chickasaw); *osak tali'* (the nuts, *osak*, hickory, *tali*, rock, Chickasaw); *otche* (Creek, cf. Simmons [1822] 1973)

*pakan'ahtik* (Plains Cree), *pummockóner* (nuts that lie in heaps [storage], Carolina Algonquians)

*wanaku'ʔka* (Catawba)

*ya* (hickory nuts, Yuchi)

*yahu'lu* [*yahu'li*] (Cherokee)

***Carya alba*** (white) (= *C. tomentosa*)

*assenamins* (Strachey wrote this Powhatan word as *assunnomeindg* in [1612] 1953. He also spelled it *assinenans*, and identified both as “walnuts.” Because of a linguistic comparison, Siebert 1975 included the name here. Related words in Fox, Ojibwa, and Delaware refer to *Acer saccharum*, although that species does not grow near Jamestown where Strachey recorded the names. The root of these words is */\*aʔsenyi/*, rock or stone, and that is not applicable to the maple. The final */\*-eminsy/* means drupe-bearing bush or tree. Siebert found the Munsee dialect of Delaware using the name *asená-minsi* for these trees, but the Ontario Delaware has *ptukwíim*.)

*astichk* (Onondaga)

hard-bark hickory; white [white-heart] hickory

hickory grubs (used by Williams [1837] 1962)

*mi'tigwabak'* (*mi'tigwab*, bow, *ak'*, wood, Ojibwa)

mockernut [hickory] (a name applied to these trees by the 1840s, presumably because they resembled a more desirable species)

*pinhudi'* (*pin*, hickory, *hudi'*, wood, Biloxi)

*skipeimeysee* (Shawnee, fide Edgar 1891; */\*-eminsy-/* means drupe-bearing bush or tree)

*uksak hata* (*uksak*, hickory, *hata*, white, Choctaw)

***Carya aquatica*** (growing in or near water)

bitter pecan

*penossv* (Muskogee)

swamp hickory [swamp-hickory]

water hickory [pignut]

***Carya cordiformis*** (in the form of a heart)

bitter-nut [bitternut hickory]

[red, white, swamp]-hickory

*noyer dur* (hard walnut, Quebec)

*o:cáktikbî* (astringent nut, Mikasuki); *oce-tofkv* [*tóktv*, *oci:tó:kfan*] (*oce*, hickory, *tofkv*, bitter and sour, Muskogee); *ochatakba* [*ochaatakba*] (*ocha*, hickory, *takba*, a taste between bitter and sweet, but not sour, Alabama)

[pig-hickory] pignut [hognut] (originally applied by Shakespeare in 1610 to *Bunium* in the Apiaceae; the allusion is problematical regarding whether it meant nuts eaten by pigs or part of their anatomy; the literary

figure *Don Quixote* used the term for acorns in 1711, but by 1760 it was applied to the fruits of *Carya*)

*pin'hu paxka'* (*pin*, hickory, 'hu, wood, *paxka'*, sour, Biloxi)

***Carya floridana*** (of Florida)

scrub hickory

***Carya glabra*** (without pubescence, smooth)

[broom, black, brown, red, switch, switchbud, white] hickory

pignut [hickory] (see notation under *C. cordiformis*)

***Carya illinoensis*** (of Illinois)

*aph'fo'tka* (Ofo)

*damzá* (Otomí, Hidalgo)

*nogal* (Texas); *nogal de Cuilapan* (Culiapan walnut, Oaxaca); *nogal de nuez chica* [*de nuez lisa, liso, morada, pecanero*] (small [smooth nut, smooth, purple, pecan] nut walnut, Texas, Mexico)

*nuez encarcelada* (nut in jail, Texas)

*o:cákî* (hickory nut, Mikasuki); *o:cáimaknî* (nut meat, Mikasuki);

*o:cáká:pî* (*à:pî*, tree, Mikasuki)

*oce* [*ocî, otche*] (the nut, Creek); *oce entvkacketv* (*oce*, hickory, *cvpko*, long, Creek); *ocE mahhe* [*o:cimahhî, ocî:máhh-i*] (*oce*, nut, *mahhe*, real, Creek); *ocî:yápi* (*oce*, nut, *apî*, tree, Creek); *ocecvpkce* [*oce-cápkuce, oce-tvkác-kv, oce-cvpko*] (*oce*, hickory, *cvpko*, long, Muskogee); *oksak fula* (*oksak*, nut, *falaia*, long, Choctaw); *osak falha'* (*osak*, nut, *fala'*, long, Chickasaw), *fala* (Choctaw; cognate with Chickasaw)

*on-ku-a* [*do'nä'i, don'ai*] (oily tree, Kiowa)

*pacana* (Spanish); *pacane* (French); pecan [pecaunes, paccan, pekan] (dating from the 1770s in English; from the native name for "nuts" in various Algonquian languages, such as Abenaki *pagann*, nut, Abenaki *pagon*, walnut; Cree and Menomini *paka:n* [*pekan*], large nut; Fox *paga:ni*, large nut; Miami *pakani*, nut; Miami-Illinois *pakaani*, nut, pecan); Ojibwa *pagan'*, Shawnee *paka:ni* [*paka:na*], nut; Atakapa *pa'kan nee*; the Unami-speaking Delaware called the pecan *ká-se-m*; the cognate Shawnee was *ka-Te-mi*; it is not clear if this is cognate with "pecan"

*pintxo'gon udi'* (pecan tree, Biloxi; *pintxo'gonni'*, the nut)

*ru* (Tunica; this may belong here, or it may be generic)

*so:-hi a-ni-nv-hi:-da'* (long nut, Cherokee)

*wa-da'-çto-çta* [*hi*] (Osage)

*yaga-sola* (*yaga*, tree, Zapotec, Oaxaca)

***Carya pallida*** (light in color)

[pale, sand] hickory

The first Europeans to see hickories in the New World were on the de Soto expedition in 1539, when they recorded them northwest of Gainesville. Soon after leaving *Ocale*

(modern Ocala) the group “passed an uninhabited region ten or twelve leagues in extent which lies between the two provinces [*Ocale* and *Potano*], in which there are large forests of walnuts, pines, and other trees unknown in Spain” (Garcilasco in Swanton 1939). No walnuts grow in that area, so he must have meant hickories (Wunderlin and Hansen 2002).

This genus emphasizes how spotty and idiosyncratic ethnohistoric records of indigenous people can be. It is well known that people throughout the southeastern states valued the fruits of both hickories and pecans, as witnessed by the Powhatan name of hickory. Harriot ([1590] 1972) was among the first people to record the importance of *Carya* in the New World, although the term “walnut” at the time included both *Carya* and *Juglans*. Under the heading “Oyle” [oil], he wrote: “There are two sorts of *Walnuttes* both holding oyle, but the one farre more plentifull than the other. When there are milles & other deuises [devices] for the purpose, a commodity of them may be raised [gathered].”

Moerman (1998) lists only the Choctaw of the Muskogean people using them; however, there are numerous other records of *Carya*. One of the oldest associations of indigenous people with pecans was from the prehistoric remains at the Ozark Bluff-Dweller site in Arkansas. There Gilmore (1931) found pecan hulls. Leonard Blake, the renowned student of plant remains who worked with Hugh C. Cutler (1912–1998) at the Missouri Botanical Garden, wrote Marie Standifer in 1988. In that letter he clarified that the pecan “does not grow in the area [of Ozark Bluff], carried in from lowlands of the Arkansas valley.”

Perhaps the first historic account of Muskogean people using *Carya* came from the de Soto expedition. Historical accounts of that time noted the Chickasaw, in what is now New Madrid on the Mississippi River in Missouri, using pecans (Hedrick 1919). *Carya* use was further elaborated by surveyor Bernard Romans ([1775] 1961). He wrote that the Chickasaws and Choctaws went “gathering nuts and making their milk.” While he did not record it, the Choctaw name of hickory milk is *uksak* [*oksak*] *ulhkom*. Of the Chickasaws, he noted, “they likewise use hickory nuts in plenty, and make a milkey liquor of them, which they call milk of nuts; the process is at bottom the same as what we use to make milk of almonds; this milk they are very fond of, and eat it with sweet potatoes in it.” He recorded that the Choctaws “make many kinds of bread...with the help of water, eggs, or hickory milk; they boil the esculent convolvulus [*Ipomoea batatas*].”

In 1773, Bartram ([1791] 1958) recorded that *C. ovata* was important to the Creeks of Georgia. He wrote: “The Creeks store up the...[shellbark nuts] in their towns. I have seen above an hundred bushels of these nuts belonging to one family. They pound them to pieces, and then cast them into boiling water, which, after passing through fine strainers, preserves the most oily part of the liquid; this they call by a name which signifies Hiccory milk; it is sweet and rich as fresh cream, and is an ingredient in most of their cookery, especially homony and corn cakes.” This practice extended at least as far north as New Jersey where the Delaware also extracted hickory milk (Kalm [1753–1761] 1972).

Alabama-speaking people have a dish they call *ochahotka* (*ocha*, hickory, *hotka*, sofkey). Creeks call it *oce nehv osafke* (*oce*, hickory, *nehv*, fat, *osafke*, sofkey). This is a dish made by adding hickory nut meat to corn after it is cooked (Sylestine et al. 1993). Sofkey itself, a word taken from the Creek *osafke* [*sáfki*] cognate with Alabama *hotka*, was served

hot or cold and generally without other seasoning. It is drunk or eaten with a spoon, depending on the consistency, which varies between a thin gruel and watery porridge.

The Choctaw called a dish made of hickory nut meat and parched corn beaten together *oksak bahpo* (*oksak*, nuts, *bahpo*, ground up maize). No mention has been found among other people of securing nuts from insects by “the smoke-drying process and then, in small quantities encased in airtight mud cells in the same manner that the mud daubers (*lukchuk chanuschik*) preserved their spiders” (Campbell 1959).

Pecans were eaten by people in Louisiana, surely both the Choctaw and Natchez, and they valued *C. illinoensis* oil for seasoning their food (Hedrick 1919). The Seminoles also consumed the nuts of *Carya*, although their name is generic for both pecans and hickory nuts (Sturtevant 1955). Hedrick (1919), Gilmore (1919), and Moerman (1998) give ample records of other indigenous groups using *Carya*.

*Carya alba* and other species were used by the Cherokee as food (Hamel and Chiltoskey 1975). Similarly, the Iroquois ate *C. cordiformis*, the Omaha ate *C. glabra*, and the Comanche and Osage ate fresh and stored pecans (Hunter [1823] 1973, Moerman 1998).

Indigenous people used wood from *Carya* to make baskets, bows and arrows, corn beaters, blowgun darts, and in tool handles and other items (Gilmore 1919, Sturtevant 1955, Hamel and Chiltoskey 1975). During the 1800s, the wood was considered prime for barrel hoops (Porcher 1863). More recently, *C. cordiformis* wood was used for wheel stock, handles, and fuel, the trees being first cultivated in 1689 (Vines 1977). *Carya glabra* branches were made into brooms because of their tough, flexible stems, and used for fuel, tool handles, wagons, and agricultural implements (Vines 1977). Pecan wood has been used for furniture, flooring, agricultural implements, and fuel (Vines 1977). Pecans have been cultivated by descendants of Europeans in America since 1766 (Vines 1977). Bark was made into rope, called *baluhchi* (Choctaw) or *ochahobaski* [*ochaobaski*, *ochaabaski*] (*ocha*, hickory, *ho-*, third person plural prefix, *baksi*, rope, Alabama).

Several species of *Carya* were used to make dyes. Kalm ([1753–1761] 1972) wrote that the people in Pennsylvania used it: “Woollen and linen cloth is dyed yellow with the bark of hiccory.” Porcher (1863) wrote, “A dye for woollens used on the plantation is made from that of most of the species.” He added, “To color yellow.—Take three-fourths of hickory bark, with the outside shaved off, and one-fourth of black oak bark done in the same manner; boil them well together in a bell metal kettle until the color is deep; then add alum sufficient to make it foam when stirred up, then put the yarn in and let it simmer a little while; take it out and air it two or three times, having a pole over the kettle to hang it on, so that it may drain in the kettle; when dry rinse it in cold water.”

The Choctaw spread leaves of *C. alba* to discourage fleas (Bushnell 1909). The Iroquois mixed hickory nut meat with bear oil as mosquito repellent (Moerman 1998).

The Cherokees made remedies from *Carya*. They used them for female problems, against colds, excessive bile, as a diaphoretic and emetic, and the bark was applied to cuts and chewed for sore mouth (Hamel and Chiltoskey 1975). The Delaware used the genus for female problems and as a tonic; the Iroquois and Meskwaki used at least *C. cordiformis* as medicine (Moerman 1998). Pecans were medicinal as far west as the Comanche and Kiowa (Moerman 1998).

Porcher (1863) noted of *Carya* ashes: “A cement for cisterns, as hard as marble, and impenetrable by water forever, is made of wood ashes two parts, clay three parts, sand

one part, mixed with oil.” Ashes were also used to make lye, which was used to process corn into hominy.

### ***Cassytha*: Love Vine**

(From Aramaic *kesatha*)

When Linnaeus was writing his *Species Plantarum*, he was faced with two completely different genera of parasitic vines. Authors before him had put these vines in the same genus, *Cuscuta*. Linnaeus realized that two genera, in two distinct groups that are now called families, were involved, and he began searching for a second name. Being inventive and proficient in languages, he borrowed from cognate sources and came up with both names. One of these he retained as *Cuscuta* (Convolvulaceae). The other he called *Cassytha* (Lauraceae).

Several scholars have said that *Cassytha* is from Greek *kassyō*, *kassyein*, to sew or patch; in Latin *cassis* means web, hunting net, spider’s web; in Akkadian *kasitu*, binding. They also record that *Cuscuta* was derived from Arabic *kusuta*, *kshuta*, *keskhut*, or *kusu*. What they have not generally said is what is meant by the Arabic and its cognate Aramaic word *kesatha*. Many years back, I looked into the situation and discovered that *Cassytha* is based on Arabic and/or Aramaic words meaning “a tangled wisp of hair” (Austin 1979). That aptly describes the masses of matted stems that cover the host plants.

Since Linnaeus gave us the genus *Cassytha*, many more species have been discovered. We now know of 20 species in the genus, most of them confined to the Old World, and with 13 endemic to Australia (Mabberley 1997). Usually a single species, *C. filiformis*, is considered indigenous to the Americas.

*Cassytha* is a member of Lauraceae, the same family as avocado (*Persea americana*), red bay (*P. borbonia*), laurel (*Laurus nobilis*), lancewood (*Ocotea coriacea*), sassafras (*Sassafras albidum*), and other familiar plants. Yet, all these familiar species are trees. Many wonder how it is that a parasitic vine is included in the same family. All the external habit differences disappear if one examines only the flowers and fruits. Flowers in *Cassytha* are built exactly the same as in the other genera, with whorls of anthers in threes and valvately dehiscent anthers. Fruits in *Cassytha* are drupes like all the others. One thing that is missing, or at least present in small quantities, is the aromatic oils so prominent in the other genera. However, most would conclude that those antiherbivore chemicals were probably unnecessary when the life-form was reduced to the parasitic mode.

Parasitism has arisen in numerous plant families in Florida including the Convolvulaceae (*Cuscuta*), Ericaceae in the broad sense (*Monotropa*), and Gentianaceae (*Voyria*). Many of these like *Cassytha* have been proposed as monotypic families with only the parasites included. However, all modern students have concluded that each is simply a highly specialized member of a larger group.

***Cassytha filiformis*.** a. Stem parasitizing another plant, b. Stem on host with haustoria. c. Detail of branching, d. Inflorescence, e. Flower in first (or female) stage, f. Longitudinal section of first stage, g. Flower in second (or male) stage, h. Longitudinal section of second stage, i. Staminodal nectary. j. Stamen and nectaries, k. Stamen before dehiscence. l. Stamen dehiscenced, m. Floral diagram, n. Fruit. *Drawn by Priscilla Fawcett. Correll and Correll 1982.*

*Cassytha filiformis* is the only pantropical member in the genus. It has many names in indigenous languages in the Old World, especially in the Indian peninsula region. The first common name recorded for the Old World was from the Malabar Coast of India where Dutch botanist Hedrik van Rhee de recorded the name *acatlia-valli* in the late 1600s. That name is most similar to the Sanskrit *akásvalli* (sky vine), but it is also related to *akáshvel* (sky vine, Bengali), *akáshwel* (sky vine, Marathi), *acatsjabulli* (maybe also sky vine, Malayalam), and *amarbeli* (live-forever vine, Hindi).

Similarly, there are many indigenous names in the Malay Peninsula. Those for which there are translations are Javanese *rambut puteri* (princess's hair) and *tali puteri*

(princess's thread). In Sudanese, it is *sangga langit* and in Bangka, it is called *akar pengalasan*.

*Cassytha filiformis* is considered a native of the New World although no indigenous language names for it have been found. That particular fact makes me wonder if the recorded uses are autochthonous or imported with people from the Old World. At least some of them probably are native to the New World because they are mixtures with other plants known only from that region. So, maybe the absence of evidence among common names is insufficient to exclude native usage. On the other hand, perhaps the uses with native American plants have been invented since the Old World uses were introduced. We have insufficient data to draw a conclusion at this point.

Many of the common names in the Americas refer to love, as in love vine, *liane amitié* (love vine, Hispaniola, Guadeloupe, Martinique), love (Montserrat), and old man berry (Cayman Islands). That concept is related to the tenacity with which the vines cling to their hosts. Surely, it has given rise to the belief that the plants are aphrodisiac in the Bahamas and Montserrat. There complex directions are given to make someone fall in love, including cooking the vine with gumbo limbo (*Bursera simaruba*) and drinking the tea with or without cream (Ayensu 1981, Morton 1981). Perhaps related is the use of *Cassytha*, either by itself or combined with *Pluchea carolinensis*, then drunk or used in baths for 9 days after giving birth (Morton 1981). Love and birth are related events.

The tangled, lush growth of the vines also has been proposed as giving rise to the belief that it promotes growth of hair or stops its loss. That view is held in the Old World (Malay Peninsula, India) and in the New World (Bahamas, Jamaica, Guyana). In all these areas, decoctions are used for washing the head and stopping falling hair (Burkill 1966). The sap is also extracted from the crushed plant and used to rid the head of lice (Morton 1981). Some think the abundant mucilage is the principal aid in hair medicines.

Yet, the "Doctrine of Signatures" concept (a plant that looks like something is useful to treat it) may not be all that is involved with these and other uses of the plants. There are potent chemicals in *Cassytha* that may even be fatal to humans in elevated doses, so surely they would inhibit or kill certain disease-causing organisms. The plants are known to contain the alkaloids nantenine (Merchant and Desai 1973), laurotetanine (Abraham 1912), the aporphine and oxoaporphine bases (Cava et al. 1968), and dulcitol (Fuzikawa et al. 1940). Of these, laurotetanine will cause cramps in small doses and may be fatal if ingested in large amounts.

In spite of those chemicals, the stems are edible in small quantities. In Jamaica and Guyana, the crushed stems are considered a vermifuge (Morton 1981). Dried and powdered plants are taken with nutmeg to relieve indigestion and stomachache. Mixed with butter and ginger they are applied to tumors. Mixed with sugar, *Cassytha* is a remedy for sore eyes and headache. In Montserrat, a tea from the entire plant is drunk to treat colds and as a purificant. *Bidens alba* leaves are mixed with love vine and boiled, and the tea is used as a treatment for high blood pressure. In the Bahamas, a tea of the plant is used to treat waist pain. In Brazil, small branches are made into an "agreeable drink" for improving the blood and stopping hemorrhage (Mors et al. 2000).

Many of the common names in the Americas compare the plants to other things. Strings and pasta are common themes. Other objects include *alcanfora del Japón* (Japanese camphor), *bejuco dorado* (golden vine), *cabellos de angel* (angel hair; also the name for cotton candy), *corde à violon* (violin string, Guadeloupe, Martinique),

*duivelsnaaigaren* (Devil's hair-net, *Surmame*), *fideos* (noodles, Cuba, Hispaniola), *fidello* (little noodles), *liane ficelle* (string vine, Guadeloupe, Martinique), *tente en aire* (tent in the air), *vermicelle* (Guadeloupe, Martinique), and yellow dodder (Montserrat). Woe-vine (USA, Bahamas) surely refers to the problems these plants cause when they parasitize plants that people wish to grow. Jaundice tie-tie (Belize) notes both medical use and the climbing habit.

Another name often used for the plants in English-speaking regions is dodder. That name and love vine are shared with *Cuscuta*, so scientists and nonscientists had and still have trouble distinguishing between these parasites. "Dodder" is a curious name for these plants. Since the 1300s, the meaning in English has been "to tremble or shake from weakness or age." A more recent meaning, dating from about the late 1500s or early 1600s, is to move (totter is cognate) or sway, as in the wind. There is a European grass (*Briza media*) that is called both dodder grass and quaking grass. The same concept probably applies to both *Cuscuta* and *Cassytha*—they tremble, at least their branch tips do, in the slightest wind. Can this also be why people in the Cayman Islands call it old man berry?

Dodder has been applied to *Cuscuta* since about 1265, so it is reasonably certain that use of that name for *Cassytha* is more recent. *Cuscuta* is native to Europe; *Cassytha* is not.

Some of the references in common names are not at all obvious. For example, in Brazil *Cassytha* is called *cipó-[de-]chumbo* (lead vine) or *erva-chumbo* (lead herb). I can think of only two possible reasons these names might have been applied. Either the tea made from the plants tastes or smells like lead, or drinking it induces trembling symptoms like lead poisoning. In Suriname, the Arawaks call it *karoba körö* [*karobakoro*].

My personal favorite among the common names is *liane sans fin* (vine without end, Guadeloupe, Martinique). That is reminiscent of the name given to *Cuscuta* in Sri Lanka (Austin 1979). There the Sinhalese call that parasite *aga-mula-neti-wel* (plant without beginning or end). How much more accurately poetic can one be?

### *Castanea*

(From Latin *kastanea*, Greek *kastanon*, the chestnut)

*Castanea dentata*. From Sargent 1905.

*castagno* (from Latin *kastanea*, Italian); *castan* (Gaelic); *castanheiro* (the tree, Portuguese); *castaño* (Spanish); *châtaignier* (the tree, French); *Kastanie* [*Edelkastanie*] (German); *kastanje* (Dutch); *kesten* (German, cf. Turner [1548] 1965)

chestnut (from *chesten* or *chestine* nut, applied ca. 1519; presumably *chesten* was based on *castanea*, although the Gaelic names make it likely that it was “chaste”)

*cnò gheanmnuidh* (*cnò*, nut, *gheanmnuidh*, chaste, Gaelic)

*geanm chnò* (*geanm*, chaste, *chnò*, nut, Gaelic)

***Castanea dentata* (toothed)**

*afata* (Timucua)

*apimin* [*opemens*] (first recorded as *opemens* by Strachey in [1612] 1953, Powhatan, Virginia; Siebert 1975 said the word *wápimin* occurs in all eastern Algonquian dialects, but to the Fox and Menomini it meant “maize” and to some Ojibwa it was “apple”); *wapim* [*wabim*, *woapim*] (Delaware)

[American, sweet] chestnut

*ohéhhahtah* [*o-heh-hah-tah*] (prickly bur, Iroquoian); *ohelliáta* (Onondaga); *unige'nia* [*u-ni-ge'-n(i)(a)*] (Cherokee)

*oti* [*uti*] (Choctaw); *oto* (Creek); *otowóske* (Muskogee)

prickly bur

*sagatémener* (roasting nuts, Carolina Algonquians)

*stsaù* (Atakapa)

*yarapi'* (Catawba)

***Castanea pumila* (dwarf)**

[Allegheny] chinquapin [*checkinakamin*, chincapin, chincopine, chicopin, chinkapin] (Powhatan, Virginia; Strachey [1612] 1953 wrote it *chechinquamins*; Vogel 1970 thought it meant “great seed,” but Siebert (1975) said it was from /\**ci-ʔt-l*/.jab, prick, /\**i-nkwe-*/. eye, and /\**-min-il*/. grain; cognates occur in Cree, Fox, Menomini, Ojibwa, and Penobscot)

*hachofakti* [*chefuncte*, *kefonctei*] (*hacho* means “mad” in Creek and is an honorable war title; any possible connection is obscure, Choctaw); *hachiäfakto* [*hachiifakto*, *achiifakto*] (*hachi*, tail, Alabama); *hotiyyá:ya* (maybe from *hó:ti*, sores, *yá:ya*, elder sibling, Koasati)

*hītu tu'* (*seed* small, Catawba)

*na'u o'xox* (*na'u*, bristle, *o'xox*, sharp, meaning the husk, Atakapa)

*sapúmmener* (little-stony-fruit tree, Carolina Algonquians)

*uhnagi:ni'a* [*u-hna-gi:-n(i')(a)*] (Cherokee)

It is impossible now to comprehend the changes in the North American landscape that began in 1930 when chestnut blight (*Cryphonectria parasitica* or *Endothea parasitica*) was accidentally introduced from Asia. Before the disease attacked the trees, chestnuts were common in the Eastern Deciduous Forest (Nixon 1997). *Castanea dentata* reached 120 feet tall and 3 to 4 feet in diameter (Sargent 1905, Harrar and Harrar 1946), but there

are records of one tree whose branches did not begin until 70 feet above the ground and that had a trunk 22 feet in diameter (Millspaugh 1892). Chestnuts were the dominant emergent trees in the forests, and their loss totally altered the dynamics of the region in ways that will never be completely known.

Chestnuts were important food not only for animals like the now-extinct Carolina parakeet (*Conuropsis carolinensis*), passenger pigeons (*Ectopistes migratorius*), and myriad vertebrates still extant, but also for people. Chestnuts were eaten as food throughout their range (Fernald et al. 1958, Moerman 1998, Davidson 1999).

The first record of New World chestnuts came in 1539 from Rodrigo Ranjel, secretary and chronicler of de Soto's excursion. He described *C. dentata* as "chestnuts in the land...which are like those of Spain, and grow on as tall chestnut trees" (Swanton 1939). Near the Santa Fe River in northern Florida, de Soto's company entered a Timucua village called *Cholupaha* (*paha*, house) along what is now the Santa Fe River in Alachua County, where "They found much food and many small chestnuts, but the trees that bear them are only two palms high and they grow in prickly burrs." That small chestnut was *C. pumila*.

Harriot ([1590] 1972) recorded use of chestnuts by the Algonquians in North Carolina with "Chestnnts, there are in diuers places great store: some they vse to eate rawe, some they stamp and boil to make spoonemeate, and with some being sodden they make such a manner of downbread as they vse of their beanes."

The usual interpretation is that the "acorn" later mentioned by Harriot ([1590] 1972) with the name *sagatémener* also was a chestnut. Why he used two entries with distinct names is unexplained unless the second entry was *C. pumila*. That Capt. John Smith and William Strachey also called *C. pumila* an "acorn" supports that view.

In 1612, Capt. John Smith wrote that the Virginia Powhatans, after boiling the nuts for 4 hours, made "both broath and bread for their chiefe men or at least their greatest feasts" (Rosengarten 1984). That same year Strachey wrote the name *chichiquamins* and a "kind of grain to eat." He also said *chechiquamins*, a "nut like a small acorn, good meat." Capt. John Smith recorded in 1624 that the Virginians "haue a small fruit growing on little trees, husked like a Chestnut, but the fruit most like a very small Acorne. This they call *Chechinquamins*, which they esteeme a great daintie." In 1682, Thomas Ash recorded that the people in the Carolinas used the chinquapin, and "Of the Kernel is made *Chocolate*, not much inferior to that made of Cacao" (Fernald et al. 1958).

Romans ([1775] 1961) wrote of the Creeks that for food "they dry peaches and persimmons, chestnuts and the fruit of *chamaerops* [*Serenoa*]." Bartram ([1791] 1958) only compared the taste of acorns to chestnuts, and noted chestnuts in the forests. Swanton (1946) wrote that both chestnuts and chinquapins were used as food by the Creek and Choctaw. Without mentioning who used them, Fernald et al. (1958) recorded: "The nuts were cooked in their corn-bread or, when roasted, were used as coffee." Apparently, they were referring to the Cherokee, who boiled the nuts, pounded them with corn, and kneaded and wrapped the mixture in a green corn husk to be boiled and eaten; they also used the seeds as a coffee substitute (Hamel and Chiltoskey 1975). The Iroquois made a similar bread mixture, and the preparation seems to have been common through the east (Moerman 1998). Yanovsky (1936) said seeds of *C. pumila* were eaten by people from Pennsylvania to Texas.

Of the wood, Porcher (1863) wrote: “The wood of the chestnut, though brittle, is very durable in weather. I am informed that fence-rails made of it will last over twenty years.” It was later prized for posts, furniture, hop-poles, hoops, and all kinds of elastic props and handles, railroad cross-ties, and fuel (Vines 1977).

The Cherokee made a brown dye from the bark (Hamel and Chiltoskey 1975). As usual, little information is available on dyes. Perhaps the chemicals are much like those in the related *Quercus*, being largely tannins related to quercetin and quercetagenin (Cannon and Cannon 2003).

The Cherokee and Iroquois used *C. dentata* for more purposes, including as a cough syrup, to treat sores, for the stomach, to stop bleeding after childbirth, for heart trouble, to relieve itch, as baby powder, to oil the hair, and to treat colds, rheumatism, and whooping cough (Vogel 1970, Hamel and Chiltoskey 1975, Moerman 1998). The Kosasti used *C. pumila* roots to relieve stomach trouble (Taylor 1940). The Cherokee used it for other problems, including headache, fever blisters, chills, cold sweats, and fevers (Hamel and Chiltoskey 1975).

Porcher (1863) wrote: “The roots contain an astringent principle; that of the chinquapin boiled in milk is much used in the diarrhoea of teething children. I would advise a tea made of this to be used extemporaneously in diarrhoea by our soldiers in camp. The bark of both trees contains tannin, and may be used in tanning leather.” Later he wrote that a local physician had “used the decoction of the root and bark of the chinquapin frequently as a substitute for quinine in intermittent and remittent fever, and with decidedly satisfactory results... Hot water is poured over the root and bark, and a large quantity taken during the twenty-four hours.” Millsbaugh (1892) noted that the leaves were part of the U.S. Pharmacopoeia.

### *Catalpa*

(Named from *catapla* [*kathulpa*], the language of the Catawbas of the Carolinas where Mark Catesby discovered the tree in 1726)

*Catalpa bignonioides*. From Sargent 1905.

*Catalpa bignonioides* (resembling *Bignonia*, which see)  
bean-tree; Indian-bean  
candle-tree

catalpa (Sargent 1905 thought that the name was from Cherokee; Martin and Mauldin 2000 said from Muskogee *kvtvte*); *catalpe* (French); catalphy [patalphy] (Kentucky)

Catawba-[tree] (taken from the name of the people by that name; their original home was from north-central South Carolina to near Augusta, Georgia)

Indian-cigar [-tree]; smoking-bean

*ittotassikáya* (*itto*, tree, *tassikáya*, catalpa, Alabama)

*katalpá* (obsolete: in wider use is *wá:ka impalaná*, cow's bean, Koasati);

*kvtvte* [*kvtvr̥v*] (Muskogee)

southern catalpa

*Trompetenbaum* (trumpet tree, German)

In the 1720s, Mark Catesby was traveling in the interior of South Carolina and discovered a beautiful tree. He not only painted the tree for his book, but he also brought its seeds back to the coast. He wrote, "This tree was unknown to the inhabited Parts of Carolina, till I brought the Seeds from the interior Parts of the Country." Seeds were distributed among the settlers, and sent to England. Catesby (1731–1732) called these trees *Bignonia Urucu foliis flore sordida albo, intus maculis purpureis & luteis asperso, siliqua longissima & angustissima* (*Bignonia* with leaves like Urucu [*Bixa*], flowers dirty white and marked with purple and yellow patches scattered within, silique long and slender) or the "Catalpa-tree."

Apparently, the seeds collected by Catesby thrived in the Carolinas and Europe because Linnaeus had studied living plants in the *Hortus Cliffortianus* he published in 1738. Linnaeus followed Catesby's lead and called the trees *Bignonia catalpa*. Later it became known that *Bignonia* consisted of twining species and these trees were distinctive. By the 1770s, Italian botanist Giovanni Antonio Scopoli (1723–1788) realized that the trees should be in a distinct genus and published *Catalpa* in 1777. Thomas Walter agreed, and in his *Flora Caroliniana*, published in 1788, he named the plants Catesby had introduced into Europe *Catalpa bignonioides*.

Both William Bartram and André Michaux found *C. bignonioides* farther south than had Catesby. Bartram ([1791] 1958) found the trees in Liberty County, Georgia. He wrote that in April of 1773, he was traveling down the high road "towards Fort Barrington, on the Alatamaha, passing through a level country, well watered by large streams, branches of the Medway and Newport rivers.... The road is... bordered on each side with... tall and spreading trees, as the Magnolia grandiflora, Liquid Amber, Liriodendron, Catalpa" and numerous other forest trees.

Although Bartram ([1791] 1958) does not indicate locating *Catalpa* in Florida, he did find it there. Research by Taylor and Norman (2002) created a list of Florida plants documented by both John and William Bartram and André Michaux; the Bartrams found *Catalpa* along the St. Johns River above Lake Dexter. Although the date is not given, the plants would have been discovered between November 1765 and September 1774.

Wood is grayish brown to lavender tinged, with the sapwood lighter in color, straight grained, and durable. It weighs about 28 pounds per cubic foot and shrinks little. It is soft and moderately shock resistant but bends poorly. Uphof (1968), Vines (1977), and

Hocking (1997) recorded that the wood of southern catalpa is used for posts, poles, rails, cross-ties, interior finish, and cabinet work.

No information has been found on the Catawba or any other tribe using these trees. However, *Catalpa* figures prominently in the pharmacopoeia of the Appalachians, and to some extent the coastal plain. Surely, the settlers learned to use the plants from indigenous people.

Bark from *Catalpa* has been used to expel intestinal worms, and a decoction is also mildly laxative. Not only are the seeds used to treat intestinal worms, but they also induce vomiting. Leaves have been applied as a poultice to skin wounds and abrasions (Krochmal 1968, Krochmal and Krochmal 1973).

Porcher (1863) was heavily influenced regarding this native *Catalpa* by the reports of medical use of another species in Asia. He wrote that *Catalpa* “[g]rows in the upper and lower country of South Carolina; collected in St. John’s.... The physicians at Naples, after the favorable report of [Carl Pehr] Thunberg and [Engelbert] Kæmpfer, as well as those of Brera, have given incontestable evidence of the advantages resulting from its use in asthma. The decoction of the fruit is also employed.... Kæmpfer says he also applied the leaves to the painful part. Poultry are said to thrive on and to be fond of the seeds. The timber makes durable posts. I find no notice of the plant in the American works. The honey collected from the flowers is somewhat poisonous—resembling, though less active, that collected from the yellow jessamine [*Gelseminum sempervirens*].”

Porcher’s reference to both C.P.Thunberg (1743–1828) and E.Kaempfer (1651–1716) alludes to their work in Japan. Kaempfer was a German physician with the Dutch East Indies Company who arrived in Japan in 1690. He produced the first list of plants known from that island, published after his death. Thunberg was a Swedish physician also attached to the Dutch East Indies Company. Sir Joseph Banks at Kew Botanical Gardens promoted his work in Japan, and Thunberg published his *Flora Japonica* in 1784. Both made comments on local medical uses of *C. ovata*.

Small (1933) found that local children in the southern states smoked the ripe pods. Judging from the common names, they may have learned that from indigenous people. Simply stealing a forbidden smoke among children may not be the only reason for Small’s observation. Perkins and Payne (1978) record that the pods are smoked to relieve asthma, as originally indicated by Porcher (1863). Pods are also thought to have cardiotoxic properties (Foster and Duke 1990).

Sargent (1905) wrote that *C. bignonioides* contains “a bitter principle and is a tonic and diuretic.” Later these compounds were identified as catapol, an iridoid glycoside (Mabberley 1997). Perkins and Payne (1978) noted that the bark and pods include the glycoside catalpin, a bitter principle, sugars, and tannin. Presumably, the catalposide and allied compounds found in *C. ovata* of Asia are related chemicals (Hsu 1986).

Moreover, at least two species of *Catalpa* in Asia are used as medicines (Duke 2003). Those plants include *C. bungei* and *C. ovata* (= *C. kaempferi*, cf. Wu and Raven 1998). Nearer to Florida, *C. longissima* is used to treat bleeding, blennorrhagia, dysentery, fever, and sore throats in Hispaniola (Liogier 1978, Duke 2003).

The catalpa sphinx moth (*Ceratomia catalpae*) is able to sequester the poisonous compounds in the leaves and feed with impunity on them (Kimball 1965). When it does so, the leaves produce more extrafloral nectaries that attract insects that attack or remove the eggs or larvae of the moths (Mabberley 1997).

*Catopsis*

(Probably from Greek *katopsis*, sight, *katoposios*, visible)

*Catopsis floribunda*. a. Flowering habit, b. Complete flower (above) and longitudinally dissected (below), c. Ovary. d. Ovule. e. Capsule, closed, f. Capsule dehiscent (above) and seed (below), enlarged, g. Floral diagram. Drawn by Priscilla Fawcett. Correll and Correll 1982.

*asômcô:bî* (big Spanish moss, Mikasuki); *asson-takko* [*assonrakkô*] (*assûnwv*, Spanish moss, *takko*, big, Creek)  
wild pine (“pine” is short for “pineapple,” Florida)

*Catopsis berteroniana* (for Carlo Giuseppe Bertero, 1789–1831, Italian physician, botanist and explorer)  
mealy wild pine (Bahamas)  
*pata de gallo* [*pié de gallo*] (chicken foot, Chiapas)  
powdery strap airplant (Florida)

*Catopsis floribunda* (many-flowered)  
*ananas sauvage* (wild pineapple, Guadeloupe, Martinique)

Florida strap airplant (Florida)

***Catopsis nutans*** (nodding)  
 air-plants  
 wild-pine

August Grisebach created the genus *Catopsis* in 1864, when he named both *C. nitida* and *C. nutans*. In the years since, enough new kinds have been found so that there are now 19 tropical American species (Smith and Downs 1977).

Seminoles used the water trapped in the base of the plants for cooking during the dry season (Sturtevant 1955).

***Cayaponia***

(Brazilian Antônio-Luiz Patricio da Silva Manso, 1788–1818, named the genus for the Cayapó, a group of Gê-speaking people of highland eastern Brazil)

***Cayaponia americana*** (from America)

American melon-leaf [American melonleaf] (Florida)  
*bejuco de finca* (farm vine, Dominican Republic); *bejuco de torero*  
 (bullfight vine, Puerto Rico)  
*concombre [bâtard, diable, hallier, marron]* ([false, devil's, thicket,  
 wild] cucumber, Guadeloupe, Martinique); *ti concombre chien* (little dog  
 cucumber, Guadeloupe, Martinique); *ti concombre hallier* (little thicket  
 cucumber, Guadeloupe, Martinique)  
*torchon* (dish cloth, Haiti)

***Cayaponia quinqueloba*** (with five lobes on the leaves)  
 five-lobe melon-leaf [fivelobe melonleaf] (USA)

The two Florida species are rare, and I never saw them in 31 years of fieldwork. *Cayaponia americana* is known only from Miami-Dade County (Small 1933, Wunderlin 1998). This species also occurs in the Bahamas, and south through the Caribbean to the Lesser Antilles, but it is absent from Jamaica (Goodding et al. 1965, Adams 1970, Correll and Correll 1980, Acevedo-Rodríguez et al. 1996).

*Cayaponia quinqueloba* is known only from Alachua County (Small 1933, Wunderlin 1998). The northern Florida species is endemic to the southeastern United States, ranging from east-central Texas, to Georgia, South Carolina, and northern Florida (Radford et al. 1968, Correll and Johnston 1970, Diggs et al. 1999).

Most of the species seem to be Brazilian, and that is where the greatest use has been (Hocking 1997). Quattrocchi (1999) lists over 30 common names for Brazilian species. People on Ilha Marajó at the mouth of the Amazon River in Brazil call *C. triangularis* the *purga de gentio* (Indian's purge, literally "gentile's purge"). In the 1940s, it was a "popular medicine" as *purgativo energético* (drastic purgative) (LeCointe 1947). All

species appear to have cucurbitacins, which are somewhat toxic triterpenes with a bitter taste (Mors et al. 2001). Commercial preparations in Brazil are made from several species and even other genera (Mors et al. 2001).

*Cayaponia kathermatophora* is grown as an ornament, and jewelry is made from its seeds (Robinson and Decker-Walters 1997). *Cayaponia ophthalmica* is a treatment for conjunctivitis (Mabberley 1997). The crushed leaves and stems of *C. glandulosa* of Peru and Colombia are used for liver problems and as an insect repellent by the Tikunas of Río Loretoyacu (Schultes and Raffof 1990). Seven species are used in northwestern South America by the Kofán, Kubiyari, Makuna, Matapié, Puinave, Taiwano, and Tikunas (Schultes and Raffof 1990). *Cayaponia racemosa*, called *camara* (room?, Mexico, Salvador, Panama), and *xta'keej* (deer feces; *xta'*, feces, *keeh*, deer, because of the fruit, Yucatan), is sold in Mexican pharmacies as a tonic, especially for cattle (Hocking 1997). There are no recorded uses in the Caribbean, but the name *brionia* (noting the similarity to *Bryonia*, Cuba) compares it to a notoriously laxative European cucurbit.

Many places have names for their species, including *ak'il k'aak* [*akilkax*] (chicken vine, Maya, Yucatán) for *C. alata*. People in Honduras say *sandía de monte* (wild watermelon) or *granadilla de monte* (wild passiflora) for *C. microdonta*. In El Salvador, *C. attenuata* is *taranta* (craziness), *hierba de tamagaz* (snake herb, the *tamagás* is the viper *Bothrops*), *retámara* (resembling *retama* or *Spartium*), and *bola de ratón* (mouse testicle, Sinaloa). Salvadorians have used the stems to clean clothes (Standley 1931).

### *Ceanothus*

(From Greek *keanonos* or *keanothos*, applied by Theophrastus, 372–287 B.C., to a corn-thistle, *Carduus arvensis*)

***Ceanothus americanus*.** From Britton and Brown 1897.

***Ceanothus americanus*** (of America)

*kikuki manito* (spotted snake spirit, Meskwaki, Menomini, Potawatomi, Ojibwa)

red-root [redroot]

*Säckelblume* (purse flower, German)

*tabe-hi* (*hi*, plant, Omaha-Ponca)

*tauchima hobok* (*hoba*, similar to, Choctaw)

[Indian, New Jersey, Jersey]-tea

Linnaeus described the first species of *Ceanothus* in 1753, calling it *C. americanus*. Leonard Plukenet had commented on the species in London in 1696 and Jan Commelin had discussed the species from the plants grown before 1697 at the garden in Amsterdam. It is not obvious that either of them knew of the medical traits of this New World plant. There are now 55 species in this North American genus (Mabberley 1997).

Missouri River people (Lakota, Omaha, Pawnee, Ponca) made a tea from the leaves, and burned the wood when other kinds were not available (Gilmore 1919). The Menomini and Winnebago of Wisconsin and Meskwaki of Iowa also used the leaves as tea (Yanovsky 1936). Although during the Revolutionary War *Ceanothus* was used as a substitute for tea (Vogel 1970, Krochmal and Krochmal 1973), there seem to be no records of indigenous people in the northeastern states using it that way.

People in the eastern parts of North America mostly used *Ceanothus* as medicine. For example, the Alabama made a decoction of the roots as a remedy for injured legs and feet (Swanton 1928a, Taylor 1940). The Cherokee took a root infusion for bowel problems and put it on aching teeth (Hamel and Chiltoskey 1975). The Ojibwa used a root infusion as a laxative and for pulmonary troubles (Moerman 1998). The Iroquois used the roots as an abortifacient, against diarrhea, for colds, and venereal diseases; they used the bark to treat sores and sore mouth (Moerman 1998). The Menomini considered a root infusion good for all stomach problems, and the Meskwaki mostly used it for bowel troubles (Moerman 1998). Probably this is the species used by the Choctaw for lung problems (Taylor 1940).

The roots are strongly astringent, with 8% tannin content, and they contain an alkaloid that is mildly hypotensive (Foster and Duke 1990).

### ***Celtis*: Hackberry**

(Greek name used by Pliny, A.D. 23–79, for a lotus with sweet berries; described by Herodotus, fl. 484 B.C., Dioscorides, fl. A.D. 40–80, Theophrastus, 372–287 B.C., and Homer, 9th–8th? century B.C.)

Hackberry, our name for *Celtis*, is a corruption of Scandanavian names. Why the name was applied first to northern European plants (*Prunus*) and then to an unrelated species from the Mediterranean (*Celtis*) is uncertain. However, it may have been because of edible fruits in both genera.

In the high Scandanavian latitudes, there are two wild bird-cherries called “hagberry” or “hegberry.” Those names appeared in English with John Gerarde’s herbal in 1597, but they are probably based on Old Norse, *heggr*. The names are still given to *Prunus padus* and *P. avium*, as Danish *haegge-baer*, Norwegian *hegge-bär*, and Swiss *hagg-bär*. Modern Danish speakers think that “hedge” was the original reference with *hæg*, derived from *haek*. Still, an alternative meaning, at least originally, was the female

personification of evil we call a “hag.” The allusion to evil still lingers because some older people in the British Isles will not use the wood of *P. padus*—they consider it a witch’s tree (Vickery 1995). At least the fruits are not regarded as dangerous because they have been prized for jams since ancient times. Gaspar Bauhin, in the 1600s, was an exception—he considered them inedible. Besides jams, both species have been used in liqueurs, and *P. avium* is still the flavoring in *Kirschwasser*.

Linnaeus gave us *Celtis* in 1753 when he adopted the name given to the plants by the 1st century A.D. Roman author Pliny the Elder. Gaspar Bauhin had also discussed the plants and called them *Lotus fructu cerasi* (the lotus with a cherry fruit). Within that seemingly simple phrase is hidden a complicated history.

Early Greeks wrote about the *lotus*, which was supposedly the food of the Lotus-eaters (*Lotophagi*). Some say the *lotus* was “the food of the Lotophagi, which Heroditus, Dioscorides, and Theophrastus

***Celtis*.** *Celtis iguanea* . a. Flowering branch, b. Close-up of section of flowering branch, c. Staminate flower with dehiscing anthers, d. Staminate flower longitudinally dissected, e. Floral diagram of staminate flower, f. Young pistillate flower, g. Pistillate flower with perianth removed to show pistil and staminodes. h. Pistillate flower longitudinally dissected, i. Fruit, j. Diagram of pistillate flower. Drawn by Priscilla Fawcett. From Correll and Correll 1982. *Celtis laevigata* . From Sargent 1905. *Celtis occidentalis* . From Sargent 1905.

describe as sweet, pleasant and wholesome, and which Homer says was so delicious as to make those who ate it forget their native country” (Johns in Fernald et al. 1958). Many, like Joachim Camerarius (1534–1598), equated *lotus* with *celtis* in 1586. However, not everyone agrees on that. Some state that the plants eaten by those *Lotophagi* were *Ziziphus lotus*, and others think the delicacy may have been *Diospyros lotus*.

William Turner ([1548] 1965) was one of the first to discuss what we now call *Celtis*. He said, “It hath a leafe lyke a Nettel, therefore it may be called in englishe Nettel tree or Lote tree.” Another comparison, made by John Martyn (1741 in OED 1971), was about “the nettle tree, the fruit of which is far from that delicacy which is ascribed to the Lotus of the ancients.”

Nettle-tree was originally applied to the European species, *C. australis*, and later extended to those in North America. John H. Balfour (1849, *Manual of Botany*) compared the names with “*Celtis*, the Nettle-tree, or Sugarberry, has a sweet drupaceous fruit.” The American plants were still being called nettle-tree by Chapman (1897), but that name was abandoned by Sargent (1905) in favor of hackberry and sugarberry.

Florida has four species of *Celtis*, three of which have restricted ranges. Both *C. laevigata* and *C. occidentalis* are temperate species, while *C. pallida* and *C. iguanaea* are tropicals on the northern edge of their distribution within Florida. All American species have been used by people wherever they grow.

*Celtis laevigata* (smooth) is called sugarberry in the United States. That name is akin to honeyberry, a name used by the Greeks for *C. australis*, and both refer to the sweet fruits. Similarly, Catawba said *yap nyu'steiwé?* (tree sweet). Yanovsky (1936) had records of tribes eating the berries in Minnesota, Nebraska, New York, North Dakota, South Dakota, and Wisconsin. Southern tribes also ate them.

The Seminoles ate the fruits and called Florida plants *istapõ:ckí:kí* (to crunch, Mikasuki) or *kapapó: ckô* (cruncher, Creek). Similarly, the Muskogee-speaking people called these trees *kvpopockv* [*kavpóckv*, *kvpvpoockv*] (from *kvpocketv*, to crunch), which is cognate. The Alabama called the trees *kapko*, which is cognate to the first part of the other Muskogean names. Perhaps *kapko* is a simple term, although Martin and Mauldin (2000) thought the name *kvpopockv* was an imitation of people crunching the fruits.

People all across the southern United States used the plants for food or medicine. Among these were the Creek relatives the Houma, who used a decoction of bark for sore throat or the bark mixed with other items to treat venereal disease (Speck 1941). The Comanche beat the fruits into a pulp, mixed it with fat, rolled that into balls, and roasted them over a fire (Moerman 1998). Several groups in the southwestern United States, including the Eudeve, Akimel O'odham (Pima), Tohono O'odham (Papago), and Yavapai ground the seeds for food, either cooked or raw (Hodgson 2001).

*Celtis occidentalis* (western) is the upland species that is more common in the northeastern United States and adjacent Canada. The species reaches its northern limit in Quebec (Houle and Bouchard 1990) where it is called *sucré baie* (sugar berry) or *micocoulier* (from 1547, an unattributed quote, “*Lotos* is a tree named *micacoulier* in Provence”). The current spelling is derived from Provençal, although it originally came from Greek, *mikrokoukouli* (from *mikros*, small, and *kuklos*, round) (Boisacq 1923). The French name *bois inconnu* (unknown tree) hints at yet another early mystery. It is not now clear why French colonists began calling the trees that, but it may have been from La Salle's first contact with the Natchez people of Louisiana in 1682 (Swanton 1946).

The Natchez venerated *Celtis* and burned its branches in a sacred fire (Speck 1941). By the late 1930s, the Houma, who by then spoke only Creole French, had altered the original *bois inconnu* for *Celtis* to *bois connu* (known tree).

Within the Missouri River drainage region, *C. occidentalis* was used for food and wood. Names through this region include *gube* (Omaha-Ponca), *kaapsit* (Pawnee), and *wake-warutsh* (raccoon food, Winnebago). The Dakota call it *yamnumnugapi* (to crunch, because animals crunch its berries), and used it to season meat. When the Dakota first saw black peppercorns (*Piper nigrum*), they thought they looked like *Celtis* berries, and called them *yamnumnugapi washichun* (white man's *yamnumnugapi*) (Gilmore (1919). To the south, the Kiowa say it is *ya-ai-gaw* [*ya-aip-hàp*], and the Atakapa say *kon nee* (*kon*, heavy, *nee*, wood).

The Houma used *C. occidentalis* as they did *C. laevigata* (Speck 1941). The Iroquois used a bark decoction to regulate menses and as an abortifacient. The Western Keres, Meskwaki, Omaha, Pawnee, and Kiowa ate the fruits. Many of them ground the berries to make mush or mixed them with fat and parched corn to make a gruel (Moerman 1998).

This species continues down into Mexico where it is called *palo blanco* (white wood, Coahuila, Tamaulipas). In the United States and Mexico, the wood is used as fuel, in furniture, flooring, crating, cooperage, and posts. In addition, the bark is considered an anodyne and a refrigerant (Hocking 1997).

The two tropical species are better adapted to dry habitats than the usual moist regions in Florida. Perhaps that is why they have such restricted ranges in the peninsula, or maybe they grow where they do because humans moved them there.

*Celtis pallida* (pale) has been found only in Lee County on old Indian middens (Wunderlin 1998). Outside Florida, it reappears in Texas, New Mexico, and, Arizona, thence south through Tamaulipas to Argentina, Bolivia, and Paraguay (Correll and Johnston 1970). It is called desert hackberry (Arizona, Florida), *granjeno* [*grangeno*, *granjén*] (little seeds, Arizona, Chihuahua, Coahuila, Durango, Nuevo Leon, Texas), and *granjeno huasteco* (Huastec seeds, Tamaulipas).

Many other people refer to its armament and call it spiny hackberry (Sonora, Arizona, Florida), *garabato* (iron hook, Sonora, Sinaloa), *garambullo* (spiny plant, Mayo, Sonora), *gec cehd* (*gec*, thorny, Zapotec, Oaxaca), *palo de águila* (eagle's tree, Sonora), *rompecapa* (cape tearer, Sonora, Oaxaca), or *vainora* [*bainora*] (probably because of similarity with *baiguo*, *Pisonia capitata*, Sonora).

Probably the most common allusion is to the fruits, with the names *acebuche* [*acibuche*] (wild olive, Sonora), *cumbro* [*gumbro*] (Mayo, Sonora), *cúmero* (either Mayo is the basis for the Spanish or vice versa, Sonora), *cungo* (Yaqui, Sonora). The name *capul* [*capui*] (Sonora, Durango, Texas) is a comparison between *Celtis* and *Prunus*, but this refers to *Prunus serotina*, usually named *capulí*.

Presumably, the other names for the plants in western Mexico are simple terms. These include *koom* (O'odham, Sonora), *kuwavul* (Pima Bajo, Sonora), and *ptaacal* (Seri, Sonora).

The Mayo eat the fruits, make the roots into a laxative tea, and formerly used the branches for hunting bows. As with all species, the wood is used for fires and household items (Yetman and Van Devender 2002). Many other people in the southwestern United States and nearby Mexico ate the fruits, although some comment that they are astringent. I find them a little waxy, but otherwise good. The Seri preferred the wood for bows and

also made cradles from it (Felger and Moser 1985). Some have used the leaves to relieve head and stomach pains (Hocking 1997).

Judging from the number of common names and the literature on it, *C. iguanaea* (of iguanas) is the most used species in the Americas. The trees range from Texas through Mexico, Mesoamerica to Peru, Paraguay, and Uruguay. In Florida, it is known from two disjunct areas on Indian middens in Lee and Collier Counties.

This species shares the names *garabato*, *cumbro*, *palo blanco*, and *vainora* with *C. pallida*. Many of its other names refer to the nasty, curved thorns on its branches, including *berraco* (screamer, because it tears at skin, Colombia), cat-claw (Virgin Islands), *clavo verde* (green nail), cockspur (Puerto Rico, Virgin Islands), *croc à chien* (dog's tooth, Guadeloupe, Martinique), *gallito* (little rooster, Dominican Republic), *garabato blanco* (white iron hook, Sinaloa), *guachar-agüero* (bad luck), *liane pagne* (pain?, vine, Haiti), *manca montero* (cowboy crippler, Cuba), *rompe caíte* (sandal breaker), *tala gateador* (cat's claws), *thak loh* (white loh or *Pisonia aculeata*, Huastec, San Luis Potosí), *uña de gato* (cat claw, Cuba, El Salvador), *zarza* (blackberry, Cuba), *zarza blanca* (white blackberry), and *zarzaparilla cimarrona* (wild sasparilla, Cuba). Several others allude to the edible fruits—*azufaifo* (sulfury one, Puerto Rico), *cagalera comestible* (edible *cagalera*, Nicaragua), *granejo* [*granjeno*] (little seed, Veracruz and elsewhere), *grão de galo* (rooster grain, Brazil), iguana hackberry (Florida), tropical hackberry (Sonora), *jujubier des iguanes* (iguana's jujube [*Ziziphus*] tree, French Antilles), and *meloncito blanco* (white little melon). Sometimes it is called *zitsmuc* (*sits'* means snack or *hors d'oeuvre*, probably in reference to the edible fruits, Maya, Yucatan). In Belize it is wild cherry.

The other names have mixed meanings, or they have not been translated. These are *baboyana*, *barimiso*, *cagalero* [*cagalera*, *cacatera*] (El Salvador, Panama), *cagalera blanco* (El Salvador), *carocá'a* (Guarajío, Sonora), *chaparro blanco* (white thicket, Sonora), *chêne blanc* (white oak, Haiti), *coca* (cocaine, Hispaniola), *irurapia* (Brazil), *joão miúdo* (little John, Brazil), *liane crabe* (crab vine, Haiti), *marimiso*, *palo de arco* (bow wood, Sonora), *piscucuy*, and *muc* (cover, because the leaves are used to line and cover the pits where some traditional dishes are cooked, Maya, Yucatan).

There are many uses recorded in addition to eating the fruits and using the wood. The Mayas in Yucatan apply sap to sore eyes, but an excess is irritating and may cause blindness. They also use a leaf decoction bath to lower fever. The Huastecs use the shoot to bring boils to a head (Alcorn 1984). In Hispaniola, fruits and bark are considered an emollient and a pectoral. Wood from the trunks is used to make *canastas*. In Brazil, a leaf infusion is used in vaginal injections for treating leukorrhea (Mors et al. 2000). Boiled, mashed fruits are considered a specific remedy for dysentery and intestinal catarrh.

Beyond studies involving allelopathy (Lodhi and Rice 1971), few studies have been made of chemicals in the genus. It is known that *C. iguanaea* contains the sugar alcohol quebrachitol (Plouvier 1958). Moretenol has also been isolated (Santa-Cruz et al. 1975). More recently, extracts have been found cytotoxic on carcinoma cells (Ruffa et al. 2002).

In addition to all these uses, two others are seldom mentioned. All *Celtis* species may be used as a tan dye, and at least the nonthorny kinds may be used in weaving baskets (Tull 1999). The slender, flexible stems were favorites among some weavers.

Many of the fruits eaten during earlier centuries tended to be small and unassuming. The positive side of those small fruits was that they often had more flavor than those now

widely available. Regardless, the fruits of the hackberries seem to be among those that have been essentially discarded by modern societies.

There remains yet another mystery about *Celtis* that to me overshadows the others. No one seems to have ever explained if iguanas really do eat that spiny *C. iguanaea*.

### ***Centrosema*: Butterfly Pea**

(From Greek *kentron*, a spur, prickle, sharp point, the center, and *sema*, a signal, referring to the spurred standard petal)

***Centrosema virginianum*. From  
Britton and Brown 1897.**

We now call these plants *Centrosema virginianum*, although they were not always called that. Indeed, until 1837 when George Bentham transferred the species to this genus, it was placed in *Clitoria*. Later, there was a debate whether or not *Centrosema* or *Bradburya* was the correct genus.

Linnaeus, in his underappreciated role as dirty-old-man, put this species in the genus *Clitoria*. He and several of his predecessors were impressed with the similarity of the flower and that female structure. Gronovius had previously called the plants *Clitoria foliis ternatis, calycibus campanulatis geminis* in 1739–1743. Even earlier, it was *Clitorius trifolius, flore minore caeruleo* to Dillenius in 1732. They and Linnaeus knew the plants grew in Virginia, the state named for the Virgin Queen, making the names even more suggestive.

The similarity was not limited to botanist-physicians of Europe because several of the indigenous names for these plants in the Americas also make the same or related allusions. These names show a more euphemistic approach than Linnaeus's direct comments. Some of those names are *colincito* (little hill, Hispaniola), *conchita* (little shell, Puerto Rico), *conchita de Virginia* (little shell from Virginia, Puerto Rico), *consuelo de los caminantes* (traveler's consolation), *crica de negra* (negresses' cat, Cuba), *cucha de negra* (negresses' spoon, Puerto Rico), *diversion de los caminantes*

(traveler's diversion, Hispaniola), *divierte caminante* (traveler's delight, Cuba), *flor de conchitas* (little shell flower, Puerto Rico), *frijol marrullero* (wily bean, Cuba), *liane fifi* (Fifi's vine, Hispaniola), *marrullero* (wily one, Cuba), *papito* (little potato, Cuba, Hispaniola), *papito de la reina* (queen's little potato, Cuba), *papo de la reina* (queen's potato, Hispaniola), *sonajera azul* (blue tamborine, Puerto Rico), *totico* (blackbird, Hispaniola), *vaillant garçon* (brave waiter, Hispaniola), *yerba de bulla* (uproar herb, Puerto Rico), and *zapatito de la reina* (queen's little shoe, Oaxaca).

Whether or not Florida's common name for these vines has been bowdlerized or simply evolved in a different direction is unknown. Regardless, we typically call the plants butterfly pea or coastal butterfly pea. In Cuba, it is simply *azulada* (the little blue one). Mayan people in Yucatan call it *cantsin* [*k'antsin*]. Others simply refer to the twining habit by saying *corde violón* (viola string, Hispaniola), *liane corde violón* (viola string twiner, Hispaniola), or *liane violón* (string twiner, Hispaniola). The comparison with violin strings seems curious, because the same basic names are given to the parasitic *Cassytha*. Others prefer to make a comparison between *Centrosema* and the other beans by calling it *pois marron savane* (wild bean of the savanna, Guadeloupe, Martinique), *pois sauvage* (wild bean, Guadeloupe, Martinique), *pois-pois* (bean-bean, Guadeloupe, Martinique), *pois-pois vrai* (true bean-bean, Guadeloupe, Martinique), or *ti-pois* (small bean, Guadeloupe, Martinique). Only one name has been found that refers to medicinal use, *grippez* (for influenza, Hispaniola).

As might be expected from the common names, the plants have mostly been used to treat sexual problems. In most places, the plants are considered an aphrodisiac, doubtless because of the resemblance to the human anatomy. They also have been used directly in medicines.

To make the situation more complicated than many, few professional botanists and virtually all nonprofessionals do not distinguish among all the species recognized in either *Clitoria* or *Centrosema*. Moreover, they do not always distinguish between those two genera. Because of that complication, here more than in some other cases, the expert on this group, Paul Fantz, feels that many of the names cited under *C. virginianum* are actually applied to *Clitoria* species (personal communication, Jan. 2002). His experience suggests, for example, that *conchita* is a name applied exclusively to *Clitoria* and not *Centrosema*. The same may be said of other names in the list above. However, as most of us cannot distinguish these, the plants themselves are likely to be used without regard to species. That may cause problems for those being treated.

In Cuba, a decoction of roots alone or roots and flowers is considered emmenagogue. This mixture is made by placing a handful of cleaned and macerated roots in a bottle of water. A glass taken in the evening is said to promote menstruation and induce uterine contractions and to aid in *el flujo loquial*. A stronger dose of the same liquid is used as a vaginal douche. An infusion of the flowers is used in the same ways. By combining a handful each of flowers and roots in a bottle of good wine one makes a *medicamento magnifico* (magnificent medicine) that is taken in one cup a day to treat *clorosis* (a malady of adolescents involving "impoverishment of the blood," probably anemia) and for liver and intestinal problems. Seeds are said to be laxative, vermifugal, and slightly emetic. Similarly, in Hispaniola the species is used against anemia and general debility.

Within the Americas, this species ranges from Florida to Texas, and from New Jersey to Kentucky and Arkansas, then in Mexico (Sonora and Tamaulipas south), the Bahamas,

Cuba, Dominican Republic, Haiti, Jamaica, Puerto Rico, Turks and Caicos Islands, several Virgin and Leeward Islands, and in South America to Paraguay and Argentina. Roig (1945) reported *C. virginianum* as being in Africa, but that turns out to be a misidentification of *C. molle* (Fantz 1996) as *C. pubescens*. The true *C. pubescens* is found at higher elevations in southern Mexico and otherwise confined to Central America (Fantz and Predeep 1992).

The other species in the Caribbean and Mexico are reported to have the same medicinal traits. Within Cuba, there are two other species, *C. plumeri* and *C. pubescens*, that are used (Leon and Alain 1946–1953). Those species are known by the same names as *C. virginianum*. However, in Puerto Rico, *C. pubescens* is also called *flor de pito* (whistle flower), having the same suggestive overtones as the other names. In Mexico, it is known as *bejuco de patito* (little duck's vine, Oaxaca). Also in Mexico, *C. plumeri* is called *bejuco de palomita* (little dove's vine, Oaxaca), *frijolillo* (little bean, Tabasco), *mariposa* (butterfly, Campeche), and *patitos* (little ducks, Tabasco). Yet other species in Mexico are called *talmohuite* (*C. sagittatum*, Hidalgo) and *patabuil* (*C. hastatum*, Sinaloa). So, throughout the range several species have attracted attention.

Pittier (1926) reported for Venezuela what Roig (1945) called *C. violacea*, known there as *generalá* (woman with the rank of general). That plant has a reputation of being effective in curing venereal diseases and leprosy. However, it turns out that the name was completely incorrect in Roig (1945), and the plants are *Rhynchosia violacea*.

The genus *Centrosema* has 35 species in the warmer parts of the Americas (Mabberley 1997). Some are used as “green manures,” especially under plantations of rubber (*Hevea brasiliensis*) and coconut (*Cocos nucifera*). In the past four decades, agronomists have discovered that species of *Centrosema* make excellent forage crops, providing more crops per season than other plants, and with key nutrients utilized better by animals. Germ plasm is being investigated at stations in both Old and New World tropics. One of the last species described, *C. carajasense*, is used as a fish poison in Amazonian Brazil.

One of the distinctive traits of both *Centrosema* and *Clitoria* is that the flowers are rotated 180° and the banner points downward. In that position, it serves as a landing platform for pollinations. In Costa Rica, carpenter bees (*Xylocopa*) are a major pollinator of at least *Centrosema* (Janzen 1983). Bumble bees (*Bombus*), as long-distance fliers, are also important in mixing the gene pool. Also important there is Euglossine Merian's orchid bee (*Eulaema meriana*). The Euglossine bees are known mostly as orchid pollinators, but this one collects nectar from *Centrosema*. Ranges of several species of *Clitoria* are similar to some in *Centrosema*, and apparently some of the same large bees visit its flowers.

Some years ago, I was leading a class field trip near the beach in southern Florida. As we walked along, we passed over a carpet of butterfly pea in full flower. I no longer remember why I did not point it out. Still, this time I passed over the plant without comment. From behind me, one of the students yelled, “Hey, what is this plant?” Without looking back, I answered, “It is *Centrosema*, called butterfly pea. It made a much better story when it was in the genus *Clitoria*.” The student retorted, “Well, hell, look at the plant next time before answering!”

***Cephalanthus*: Button-Bush**

(Greek *kephale*, head, *anthos*, flower)

Since about the year 1340, people who speak English have been using buttons, although the litera

***Cephalanthus occidentalis*.** From  
Institute of Food and Agricultural  
Sciences.

ture of the time spelled it “boutounz.” Yet, as far as I am aware, people in the Americas never invented that seemingly simple fastener for clothes and other items. Some time after the Europeans invented the closing device, they began to apply the word to other structures. Among the things that resembled buttons to some people are plants like button-wood and button-bush. Younger people who saw the plants, and particularly the fruits, would not have given them the same names. The fruit clusters do not resemble modern buttons in the slightest. However, the fruit clusters do look like old buttons that were globular.

The first record we have of these plants being known in Europe was published by Leonard Plukenet in 1696. He called them *Scabiosa dendroides americana* (the American tree *Scabiosa*). The only similarity they have with *Scabiosa* (Dipsacaceae) is the globelike flower cluster, and Linnaeus noted the difference. In 1738, Linnaeus proposed the new name *Cephalanthus* for these trees. That name was picked up by his contemporaries and used in 1739 by Jan Gronovius and in 1740 by Adrian van Roy en (1705–1779). In 1753 Linnaeus gave us the name we use today—*Cephalanthus occidentalis*.

This species is almost confined to mainland North America, but it also ranges into Central America and the Caribbean. The trees in the United States and Canada are known from New Brunswick and Ontario, south to Florida, and west to Texas, Arizona, and California. In Mexico, they grow from Chihuahua to Veracruz, Guerrero, and Tabasco,

and south to Honduras. Button-bush is also in Cuba, but in none of the other Caribbean islands—not even the Bahamas. Given that the fruits are eaten by wildfowl, including at least seven species of ducks (Martin et al. 1951), one might reasonably expect the small trees somewhere in the Bahamas, but they are not there.

Now there are six species known in the genus; most are tropical, and *C. occidentalis* is the only one in North America. With a name like *C. occidentalis*, there should also be a *C. orientalis*, and there is. Linnaeus described that species at the same time in 1753, and he knew the species from India and Africa. There are also species in China and Taiwan, and others in the Americas, ranging as far south as Peru and Argentina.

*Cephalanthus occidentalis* has a long history of medicinal use, but apparently none of the other species has similar usage. The Chinese, who are famous for finding the medicinal aspects of virtually everything, do not seem to have used the genus either.

In Florida, the Miccosukee call these shrubs or small trees *halpáti:hosô:tí* (alligator shader); their relatives say *sakco* 'meto [*sakcomitto*] (*sakco*, crawfish, *em*, its, *eto*, tree, Creek) or *sakcô imittô* (*sakcô*, crawfish, *im*, its, *ittô*, tree, Koasati). The Choctaw called them *notêm pisa* (*noti*, tooth, *im*, its, *pisa*, eyes or vision) or *akkasoli*, and the Chickasaw know it as *shakchimitti* (*shakchi*, crawfish, *im*, its, *itti*, tree). Sometimes the Chickasaw say *shakchikoyyo* (*shakchi*, crawfish, *ikoyyo*, a word always combined). Kiowa said *ee-toñ-bà-a*. North in Canada, they are called *bois de plomb* (lead flower), apparently because of the similarity of the fruit cluster to a bullet or lead sinker used in fishing.

A number of names have been recorded in Mexico. In the northern part of its range, it is known as *mimbre* (Sinaloa) or as *mimbro* (Mayo, Sonora). That is a name given to several genera in Mexico, including *Cephalanthus*, *Chilopsis* (Bignoniaceae), *Cornus* (Cornaceae), and *Forestiera* (Oleaceae). The only similarity between them is the leaves, so the reason this name is applied to them and also to the genus *Monstera* (Araceae) is obscure. *Cephalanthus* is also called *rosa de San Juan* (St. John's rose, Texas, Durango), although association with that saint is obscure unless there is a medicinal connection. Some people think they smell like jessmine (*Jasminum*, Oleaceae), and say they are *jasmín* (Michoacán, Guerrero). Both have nocturnally fragrant flowers, so the analogy is reasonable. No meaning was found for *cahuapate* (Náhuatl, Oaxaca), but the Zapotec simply say *yo yado* [*ya yado*] (flower, Oaxaca). The southernmost names located are *uvero* [*umbero*] (grape tree, Tabasco). The rounded fruit cluster is reminiscent of grapes. In Cuba, the species is known as *aroma de ciénaga* (marsh perfume, Cuba), *aroma de laguna* (bay perfume, Cuba), and *cavellina de ciénaga* (marsh carnation, Cuba). All of those names refer to the fragrance of flowers similar to *jasmín* in Mexico, but add the habitat as a "binomial" to distinguish taxa.

In the United States, the most frequently used name is button-bush, but there are others that are (or at least have been) used. These names include crane-willow, globe-flower, honey-balls, pincushion flower, pond dogwood, and snowball. Some have objected to several of these names because they have also been used to refer to other plants. For example, the name button-bush historically was also applied to *Platanus occidentalis* (Platanaceae). We also call *Platanus* (which see) the American plane tree. Snowball is also applied to *Symphoricarpos* (Caprifoliaceae), and globe flower is used for *Trollius* (Ranunculaceae). However, that is part of the beauty of common names—they describe something that has caught the fancy of the people who apply them. As

common terminology is not bound by international rules, there will be overlap. Instead of causing distress, that should cause delight in the ingenuity of the human intellect.

Even more than the indigenous names show, this was an important plant in indigenous people's pharmacopoeias. *Cephalanthus* was involved in at least five remedies by the Seminoles and was "a favorite remedy" among the Choctaw (Bushnell 1909). We have records of its use also among the Chickasaw (Campbell 1951), Kiowa (Vestal and Schultes 1939), Koasati (Taylor 1940), Meskwaki (Smith 1928), and Comanche (Moerman 1998). These represent four major language groups (Algonquian, Aztec-Tanoan, Muskogean, Shoshonean), and any plant affecting that many diverse people was important indeed.

These indigenous people used button-bush as a remedy for dysentery (Choctaw, Seminoles), as a diuretic (Seminoles), as an emetic (Meskwaki), as a febrifuge (Choctaw), for eye trouble (Chickasaw, Choctaw), and to stop hemorrhages (Kiowa). Moreover, it was an all-round tonic and analgesic, used to treat headaches (Seminoles), rheumatism (Koasati), stomachaches (Seminoles), and toothaches (Choctaw). The pollen was found in human coprolites in the Fort Center archaeological site, a Glades construction (Hogan 1978). There is no reason to assume that the pollen might be ingested for other than medicinal application by those southern Florida people who preceded the Seminoles.

Several parts of the tree were used, mostly in decoctions but also in poultices. A root poultice was applied to sore eyes. Decoctions of bark were used for dysentery and for eye problems. Root bark and trunk bark were febrifuges. Bark was also used to stop toothache. Decoction of leaves relieved rheumatism. The Comanche even used the wood to make game sticks.

Europeans and Americans in many places used the plants much as had the indigenous people. Root tea was gargled and swallowed to relieve throat irritations, severe colds, and to bring up phlegm. Mixed with other plants, it was considered a prime treatment for colds and even whooping cough. At one time, a mixture of root bark and comfrey (*Symphytum officinale*) was even considered a cure for consumption (Porcher 1863). Decoctions were also used treat skin infections. Decoctions of the bark were once considered effective for treating malarial fevers and syphilis.

Yet, by the late 1800s, the plant was considered "not important" in medicine. Although a formula for preparing the plant as a medicine was given by Millspaugh (1892), he was not impressed. He said, "The tincture...has a light, clear, orange-brown color, but transmitted light, a bitter, astringent taste, and an acid reaction." He too attributed tonic, laxative, and diuretic properties to the plants. Murphee (1965) found people in the Panhandle putting roots in whiskey to treat asthma and dropsy.

Then people began realizing that there were problems with using the plants and some of those treated developed side effects worse than the malady being treated. Some people developed violent vomiting, convulsions, and paralysis (Perkins and Payne 1978). The chemistry of the plants was examined and found to contain the toxic glycosides cephalanthin and cephalin. Both of these are hemolytic (destroys blood corpuscles) and even lead to death (Foster and Duke 1990). Also present are substantial amounts of tannins and volatile oils. Although the leaves are toxic to horses, they are browsed with impunity by deer. Therefore, it seems that the chemicals react differently in different organisms.

### *Cercis*

(From Greek *kerkis*, the ancient name used by Theophrastus, 372–287 B.C., for the redbud or Judas tree)

*arbol del amor* (tree of love, Spanish)

Judas' tree; *alberi du guida* (Italian); *arbre de Judée* (French); *arvore de Juda* (Portuguese); *Judasbaum* (German)

*olaia* (Portuguese; this Middle Eastern tree does not grow in Portugal, but was introduced and cultivated for ornamental purposes)

***Cercis canadensis*** (of America)

*ga-lo-we:-d(i)* (Cherokee)

*gaînier* (girdle-maker, but also a name for *Cercis*, whose pod resembles a girdle, French)

*kee-à-gu-la* (Kiowa)

*totakkpe* [*rvtákpe*, *rotakkpe*] (*totak*, maybe a simple term for the plants, although Martin and Mauldin 2000 suggest it imitates the crack of a whip when used in compounds, *vpe*, stem, Muskogee); *taka'sta'* [*takastaka'*, *takastak*, *takasta'*] (Chickasaw); *takaská:ci* (akin to *takáhkan*, crack in the earth or mud, Koasati)

[eastern] redbud

*yap yap pete'?* (flat tree seed, Catawba)

*zhon'-sha be hi* [*zhon'-sha be the hi*] (*zhon*, wood, *sha-be*, dark, *hi*, tree, Osage)

Cherokee children are known to have eaten the blossoms (Moerman 1998). Hedrick (1919) recorded that French Canadians “use the flowers in salads and pickles.” At least the Canadians seem to have been influenced by the edibility of the Old World species, *Cercis siliquastrum*, which has edible flowers and fruits (Hedrick 1919). In Texas, the buds, flowers, and young pods are eaten raw or sautéed (Vines 1977, Cox and Leslie 1991). However, others say the bud is poisonous because of saponins (Diggs et al. 1999).

Indigenous Americans used the tree mostly as medicine. The Alabama used an infusion of roots and inner bark for fever and congestion (Swanton 1928a, Taylor 1940). The Cherokee used a bark infusion to treat whooping cough (Hamel and Chiltoskey 1975). The Delaware used an infusion of the bark to treat fever and vomiting (Moerman 1998).

The Osage used charcoal from the wood to paint the face during battle. Only those so painted were awarded honors (La Flesche 1932).

### *Chamaecrista*

(Conrad Moench, 1744–1805, composed this name from Greek *chamai*, on the ground or dwarf, and Latin *crista*, a crest)

***Chamaecrista fasciculata*** (clustered)

*bala okchi* (Choctaw)

beeflower

*dormidera* (little sleeper, Cuba, Venezuela)

golden cassia

*kowwàkinchastoki* (*kowwayki*, quail, *im*-, its, *chastoki*, beans, Alabama); *kowwayki impalaná* (*kowwayki*, quail, *im*, its, *palaná*, bean, Koasati)

*ñajú* (Venezuela)

*otkofimpátâ:kî* [*o(th)kofempaataake*] (from *otkofi*, persimmon, *im*, its, *pataki*, bed, Mikasuki)

[showy] partridge pea

***Chamaecrista fasciculata*.** Drawn by  
*P.N.Honychurch.*

[American, prairie, wild] senna (Carolinas)

sleeping-plant [sleepingplant]

*unnagéi* (black, Cherokee)

***Chamaecrista nictans*** (blinking, moving)

*hassihassàaya* (*hassi*, grass, *hasaaya*, to sulk or play possum, Alabama)

*otkofimpátâ:kî* [*orkofimpátâ:kî*] (persimmon's bed, Mikasuki); *satá impatâ:ka* (svtv, persimmon, *em*, its, *espvtakv*, bed, Creek)

[sensitive] partridge pea  
 sensitive pea (this and the specific name alludes to the “sleep”  
 movement where the leaflets move against the rachis in the evening)  
*sim-sim* (*sim*, nasal mucous or semen, Maya, Belize)  
*tohkil* (Choctaw)  
 wild sensitive plant

Linnaeus called the sensitive pea *Cassia nictans* in 1753. Before that date Plukenet had called it *Senna spuria virginiana*, *mimosaea foliis*, *floribus parvis nicanibus* (false *Senna* from Virginia, with leaves like mimosa, and small flowers that sleep) in 1696. Linnaeus had also studied the living plants at both the *Hortus Cliffortianus* and *Hortus Upsaliensis*. When Conrad Moench (1744–1820), professor at Marburg, Germany, put the species in *Chamaecrista* in 1788, most people thought he was a devout “splitter,” just creating names where they were not needed. Subsequent studies have indicated that plants called *Cassia* were actually from more than one lineage that had converged on a similar morphology. André Michaux described *Cassia fasciculata* in the early 1800s, and it was moved to *Chamaecrista* by Edward Lee Greene (1843–1915), another devout splitter who created many “microspecies.”

The earliest record of *C. fasciculata* in Florida was pollen associated with pre-Columbian Glades people at the Fort Center site on Lake Okeechobee (Hogan 1978). Small (1933) recorded the Seminoles using *C. fasciculata* “in cases of nausea.” Sturtevant (1955) said the same species was used as medicine to treat stomachache. The Seminoles also treat urinary tract infections with a medicine made by boiling the entire plant, including roots (Bennett 1997). The Houma boiled the roots with wild beans to make a tea for treating typhoid fever (Speck 1941).

Mooney (1885–1886) found that the Cherokee drank a decoction of *C. fasciculata* for fever and an unidentified disease with symptoms including black spots and partial paralysis. The Cherokee also bruised moistened leaves with water for dressing sores (Mooney 1885–1886) and used a medicine made from roots of *C. fasciculata* or *C. nictans* to keep ballplayers from tiring and to treat fainting spells (Hamel and Chiltoskey 1975). The Meskwaki soaked the seeds of *C. fasciculata* in water until they became mucilaginous and then ate them to relieve sore throat (Vogel 1970).

Porcher (1863) said of *Cassia fasciculata*: “It is said to be as safe and as certain in its operation as the imported senna [*Senna italica*], but more apt to gripe; this may be corrected by infusing fennel seed or some other aromatic with the leaves. It is prepared in large quantities by the Shakers, and is generally collected after the seeds ripen; one ounce of the leaves is added to one pint of hot water, of which the dose is one to three ounces, repeated.” Under the synonym *C. chamaecrista*, he wrote, “The leaves are said to be purgative.”

The Mikasuki and Creek names for the plants allude to their use in ripening persimmons. They do that by “placing them in a pit lined with partridge pea plants. Layers of the plant are laid over each layer of persimmons until the pit is full” (Bennett 1997).

*Chamaecyparis*

(From Greek *chamai*, on the ground or dwarf, and *kyparissos*, cypress, used originally by Pliny, A.D. 23–79)

- Chamaecyparis thyoides*** (like or resembling *Thya* or *Thuja*)  
*achena* (Muskogee); *a'tsina* [*a'-tsi-na'*, *a-tsi:-n'*] (a loan-word from Muskogean, Cherokee)  
*amerikansk vit-ceder* (American white cedar, Dutch)  
*cedre blanc d'Amerique* (American white cedar, Quebec)  
*cedro* [*cipresso*] *blanco* [*americano*] ([American] white cedar, Italian);  
*cedro blanco americano* (American white cedar, Spanish)  
*cowahlá* (Kosasti)  
cypress (for etymology, see *Taxodium*)  
*kogelcypres* (ball cypress, Dutch)  
*ochsochráta* (Onondaga)  
*rakiock* (soft wood, Carolina Algonquian, North Carolina)  
*Scheinzypress* (shiny cypress, German)  
*vit-cypress* (white cedar, Dutch)  
[Atlantic, coast, southern, swamp] white cedar (see *Juniperus* for etymology of “cedar”)  
*witte Amerikaanse ceder* (white American cedar, Dutch?)

Linnaeus recognized three species of *Cupressus* in 1753—*C. sempervirens* in Europe, *C. distica* in Virginia and South Carolina, and *C. thyoides* in Canada. He knew the first two from living plants at the *Hortus Cliffortianus*. The third he knew only from Plukenet's drawing and from his student Peter Kalm. The first species remains in *Cupressus*, and *C. distica* was moved to *Taxodium* by A. Richard in 1810. *Cupressus thyoides* was not moved to the genus *Chamaecyparis*, created by Edouard Spach in 1841, until 1888 when N.L. Britton (1859–1934), E.M. Sterns (1846–1926), and J.F. Poggenberg (1840–1893) made that change.

The basis of Linnaeus's comment on the plants was information brought back by his student Peter Kalm. On 5 May 1749, Kalm was in New Jersey where he made a special collecting trip. He wrote: “A tree which grows in the swamps here, and in other parts of *America*, goes by the name of *White Juniper-tree*. Its stem indeed looks like one of our old tall and strait juniper-trees in *Sweden*: but the leaves are different, and the wood is white. The *English* call it *White Cedar*, because the boards which are made of the wood are like those made of cedar. But neither of these names are just, for the tree is of the cypress kind. It always grows in wet ground or swamps: it is therefore difficult to come to them, because the ground between the little hillocks is full of water. The trees stand both on the hillocks and in the water: they grow very close together, and have strait, thick, and tall stems; but they were greatly reduced in number to what they have been before....

“The marshes where these trees grow are called *Cedar Swamps*. These cedar swamps are numerous in *New Jersey*, and likewise in some parts of *Pensylvania* and *New York*. The most northerly place, where it has been hitherto found, is near *Goshen* in *New York*,

under forty-one degrees and twenty-five minutes of north latitude, as I am informed by Dr. *Colden*. For to the North of *Goshen*, it has not been found in the woods. The white cedar is one of the trees which resist the most to putrefication; and when it is put above ground, it will last longer than under ground: therefore it is employed for many purposes; it makes good fences, and posts which are to be put into the ground; but in this point, the red cedar is still preferable to the white; it likewise makes good canoes. The young trees are employed for hoops around barrells, tuns, etc. because they are thin and pliable; the thick and tall trees afford timber, and wood for cooper's work. The houses which are built of it, surpass in duration those which are built of *American* oak. Many of the houses in Rapaapo were made of this white cedar wood; but the chief thing which the white cedar affords in the best kind of shingles" (Kalm [1753–1761] 1972).

He goes on to note that the shingles are more durable than other woods, except for red cedar (*Juniperus virginiana*). Shingles are light, so there is no need for strong beams to support them, which makes it unnecessary to build thick walls. When fire breaks out, shingles do no harm when they fall, and they soak up water to prevent fire spreading. If they catch fire, they do not easily set new fires elsewhere. Apparently, there had long been a trade in white cedar shingles because he comments at length on the young shoots remaining. Kalm then criticizes the short-sighted approach the locals had taken and how it would be hundreds of years before the cedar trees could grow back. He notes, "They are here (and in many other places) in regard to wood, bent upon their own present advantage, utterly regardless of posterity." Kalm was far in advance of the ecological movement in preaching sustained yields.

When Bartram traveled in the southeast in the 1770s, he still used the name *Cupressus thyoides*. He was not sure it was the same as that species and, while on the Tombigbee River in Alabama, said, "I observed a species of Cypress; it differs a little from the white Cedar of New Jersey and Pennsylvania (*Cupressus thyoides*) the trunk is short and the limbs spreading horizontally" (Bartram [1791] 1958). That slight variation Bartram saw is part of what A.J.Rehder (1863–1949) divided into 30 varieties and forms in 1949 (Michener 1993).

It is remarkable how little information exists on the early uses of white cedar apart from that given by Kalm. The only note found is that the Ojibwa of Minnesota in 1891 used a decoction of leaves in steam for headaches and backaches and a poultice of crushed leaves and bark for headache (Moerman 1998).

Morton (1974) found the people of South Carolina using an infusion of cones in whiskey to treat asthma. People there still chew the twigs for the flavor. Morton (1974) found records of the branches being stimulant, aromatic, diaphoretic, and stomachic.

### *Chamaelirium*

(From Greek *chamai*, on the ground, dwarf, and *leiron*, a lily; the genus was established from an under-developed specimen)

***Chamaelirium luteum*.** From Britton and Brown 1896.

***Chamaelirium luteum*** (yellow)

- angel's-wand
- blazing star (used by John Bartram in 1751; usually given to *Liatris*)
- colic root [colicwort] (usually given to *Aletris*)
- devil's bit (translation of Medieval Latin *morsus diaboli*, devil's bite, in German *Teufels-abbisz*; originally applied to *Scabiosa pratensis*, and in English ca. A.D. 1540; transferred to *Chamaelirium* by 1751)
- drooping starwort
- fairy wand
- grub root [grubroot]
- heloinas (from Greek *helos*, marsh, as some species frequent bogs; formerly this species was included in this genus, as *H. dioica* and *H. sabiosa*, although as now delimited, *Helonias* is distinct)
- rattlesnake root
- squirrel-tail
- star root [starwort]
- [false, true] unicorn [root] (allusion to *Aletris*)
- unicorn plant

Although Millspaugh (1892) attributes the name "devil's bit" to "an aboriginal legend," the name was in use in the Old World during the Middle Ages (A.D. 500-ca. 1500), well before the New World was discovered. However, Millspaugh was alluding to the legend recounted in Jonathan Carver's book *Travels through the Interior Parts of North America in the Years 1766, 1767, and 1768* (Vogel 1970). The concept of "devil" did not exist among indigenous people; that is a European belief.

The name "devil's bit" was explained in 1616 as being "so called, because it sheweth as though the middle, or the heart of the root, were gnawed or bitten by some Diuell...as though the Diuell did enuie the good which it bringeth vnto men by the incredible vertues that are therein."

As Vogel (1970) explained, the name “devil’s bit” has been applied to three native American plants (*Aletris farinosa*, *Chamaelirium luteum*, and *Liatris scariosa*), and at least one other from Europe. Hunter ([1823] 1973) called a plant by that name, and editor Richard Drinnon interpreted it as *C. luteum*. However, the Osage and Kansas with whom Hunter spent his youth lived in an area where that plant does not grow (Steyermark 1963, Barkley 1986). The Osage name *sho-ma-cas-sa-es-ra-rah* means “it kills wolves” (*shoṅ-ge*, wolf) so it was a poisonous plant. That is further evidence that Hunter was talking about some other species, because *Chamaelirium* is not that poisonous. Probably, Hunter was talking about *Melanthium woodii*, which does grow in the eastern two thirds of Missouri and is notoriously poisonous to mammals (Steyermark 1963, as *Veratrum woodii*; Wiersema and León 1999). However, he may have mistaken the plant for *Arisaema triphyllum*, which is *shoṅ-ge i’-t’sé-the* (wolf killer, Osage).

As now delimited *Chamaelirium* contains the single species, which is endemic to eastern North America (Mabberley 1997). The plants grow from Massachusetts, New York, and southern Ontario west to Michigan and south through Illinois, to Arkansas and Florida (Fernald 1950, Browne and Athey 1992, Smith 1994). The first record of the species was the specimen sent to Gronovius by John Clayton in the 1730s. That sheet and a record from Canada formed the basis of Linnaeus’s description in 1753.

John Bartram was perhaps the first to record the medical qualities of these lilies (Coffey 1993). He wrote in 1751, in the appendix to the *Medicina Britannica*, printed by Benjamin Franklin, of the “[b]lazing Star, as it is called by the back [country] inhabitants, by others, Devil’s bit.... This precious root is a great resister of fermenting poisons, and the previous pains of bowels, taken in powder, or the root bruised and steeped in rum.”

Moerman (1998) does not mention these plants, although Vogel (1970) devoted almost a page to them. As they also were recorded by Jonathan Carver and George Henry Loskiel, both of whom visited the northeastern United States, the tribes were probably in New England. Those indigenous people [unspecified] chewed the root to relieve coughs and stop miscarriage (Millspaugh 1892). However, the most common use of these plants appears to have been against colic, worms, and fevers.

The first record of the use of the herbs where a scientific name was given was by physician Benjamin Barton who, in 1793, noted that they were called “blazing star or devil’s bit” (Vogel 1970). He recorded that a water infusion of its roots was used as a tonic and anthelmintic. Later physicians also used the plants for a variety of maladies, most of them associated with “male and female reproductive organs” (Foster and Duke 1990). The plants were listed in the National Formulary under the names “Helionas, Blazing Star, or False Unicorn” between 1916 and 1947. They were considered diuretic and a uterine tonic (Vogel 1970).

Core (1967) did no more than quote Millspaugh although he established that the species was used in the southern Appalachians. In that region, powdered roots were used to treat uterine disorders, pain in the head, side, or loins, poor appetite, depression, and colic. The rootstock also was used to treat intestinal worms, vitamin C deficiency, and to induce flow of urine and saliva. *Chamaelirium* is also emetic (Krochmal and Krochmal 1968). Hocking (1997) considered the plants a uterine tonic, emmenagogue, diuretic, anthelmintic, and alterative. Duke et al. (2001) concur, but provide a warning that it should be avoided during pregnancy and that Canadian regulations prohibit its use.

According to Millspaugh (1892), the plants contain chamaelirin, and Hocking (1997) added only that it also had starch.

### *Chamaesyce*

(Name used by Dioscorides, fl. A.D. 40–80, from Greek *chamai*, on the ground, *sykon*, a fig; plants are prostrate and have figlike fruits, at least to S.F.Gray who named them)

### *Chamaesyce mesembryanthemifolia.*

*Drawn by P.N.Honychurch.*

***Chamaesyce mesembryanthemifolia*** (with leaves like

*Mesembryanthemum*, Aizoaceae)

box-leaved spurge (“box” alludes to *Buxus*, Florida)

coastal beach sandmat (Florida); sandmat (Florida)

chicken weed (Belize)

*revienta caballo* (horse breaker, Cuba)

*yerba mala* (bad herb, weed, Cuba)

British naturalist Samuel Frederick Gray (1766–1828) created the genus *Chamaesyce*, removing the species from the larger *Euphorbia*. Indeed, when Jacquin named this species in 1760 he called it *E. mesembryanthemifolia*. Those who recognize *Chamaesyce* as distinct from *Euphorbia* think that it contains about 300 species spread around the world in temperate and tropical zones (Diggs et al. 1999).

On the coast north of Havana, sea bathers use the latex from these plants to cure the wounds made by urchins (Roig 1945). Elsewhere along the coast the horses who eat the plants are said to die, hence the name *revienta caballo*. The herb is also used against gonorrhea and as a laxative. It is used medicinally in Belize (Balick et al. 2000).

### *Chaptalia*

(Named by Etienne Pierre Ventenat for the French chemist Jean Antoine Claude Chaptal Count de Chanteloup, 1756–1832)

***Chaptalia tomentosa*** (pubescent)

*i:chakcobi* (deer's ear, Mikasuki); *icohackó:ma*: [*cohácko*] (*eco*, deer, *hvcko*, ear, Creek)  
sunbonnets (Florida)

The Seminoles used these herbs as medicine to treat “Deer Sickness” (arms and/or legs become useless and painful; common dreams of deer, dead and alive) and urine retention (Sturtevant 1955). Several of the other usually narrowly endemic species in the genus have been used as medicines. For example, *Chaptalia texana* is used by the Mountain Pima (Laferrrière 1994), and *C. nutans* has a name, *motitas* (Tabasco), comparing it to *mote* (*Erythrina glauca*). In Haiti, *C. nutans* is called *fwa pa nan kont* (literally, “liver is not struggling”), *pinga nèg* (the man's substance), and *toro tig* (tiger bull). All three of the Haitian names allude to cleansing the blood and digestive system as part of an aphrodisiac. *Chaptalia nutans* is used in medical preparations (Beauvoir et al. 2001). Moreover, *Chaptalia* has been shown to inhibit *Bacillus subtilis* and *Staphylococcus aureus* (Beauvoir et al. 2001).

### *Chenopodium*

(From Greek *chen*, a goose, and *pous*, foot, an allusion to the shape of the leaves; probably the plant called *chenopus* in Greek by Pliny, A.D. 23–79)

***Chenopodium album*** (white, alluding to the color of the leaves)

*Ackermolten* (field atriplex, Fuchs 1542, German) *ansérine* (of geese, Quebec)

*armuelles silvestre* (wild atriplex, from a 1557 herbal, Spanish); *arroche sauvage* [*arroche salvuaige*] (wild orach, from a 1575 herbal, French); *atriplice salvatica* (wild atriplex, from a 1551 herbal, Italian)

*bàtl-sai-añ* [*bàtl-sai-ya-doñ*] (stink weed, Kiowa)

blue weed

*chou gras* (fat cabbage, Quebec)

dirty dick (England)

dungweed (England)

*eto" ditli* (leaf is blue, Slave)

fat hen (in use by 1795); *poulette grasse* (fat hen, Quebec)

*Gänserfuss weisser* (white goosefoot, German); [white] goosefoot (in use by 1548)

*gensz fusz* (in use by 1548, Dutch)

***Chenopodium*.** *Chenopodium album*, a. Habit, small plant, b. Flowering branch, c. Flowers, with sepals and petals erect (above) and reflexed (below), d. Utricle. e. Seed. *Drawn by Regina O. Hughes.* From Reed 1971. *Chenopodium berlandieri* (inset in upper right corner). From Britton and Brown 1896.

[common] lamb's quarter(s) (in use by 1773 in England, USA, Bahamas)

muckweed (England)

[common] pigweed (in use by 1844, USA, Bahamas)

*shokhimpa* (*shokha'*, *hog, impa'*, food, Chickasaw)

wild spinach

wilde areche (used by William Turner in 1558)

*wilde melde* (wild atriplex, from a 1549 herbal, Dutch)

*withiniwpakwatik* (Cree)

***Chenopodium berlandieri*** (named for its discoverer Jean Louis Berlandier, 1805–1851)

*ashecani* (with a name like “ash-can” one has to wonder if Martínez 1979 was not kidding us!)

*belle dame sauvage* (wild *Chenopodium*, Du Pratz in Louisiana in 1758)

*choupichoul* (Natchez name given by Du Pratz in 1758)

*chuale* [*chual*, *cual*] (from Náhuatl, *tzohualli*, seeds used to make tamales called *chual*, Mexico)

*cotasula* (Guarijío, Chihuahua)

*huauzontle* [*huauzontl*, *huauzontli*, *huanzoncle*] (*quauhtli*, eagle, *tzontli*, hair, Náhuatl, Mexico)

*kovi* (Akimel O’odham [Pima], Arizona)

lamb’s quarter(s)

*melden* (Dutch, cf. Harriot 1580)

pit-seed goosefoot

*quelite cenizo* (ashy greens, Mexico); *quelite salado* (salty greens, Mexico)

*taani*’ (Chickasaw); *tahwv* (Muskogee)

When Linnaeus named *Chenopodium* in 1753, he knew 22 species; 19 were from Europe and nearby Asia. From the Americas he knew *C. ambrosioides*, *C. anthelminticum*, and *C. virginicum*. In adopting the genus he continued a name that had been given by Swiss herbalist Gaspar Bauhin in 1623, and much earlier by Pliny in southern Europe. Today the genus contains ~100 species (Mabberley 1997).

Earlier Europeans lumped what is now called *Chenopodium* with other plants that we now put in *Amaranthus* and *Atriplex*. Fuchs (1542) included *Atriplex hortulensis* with *Chenopodium album* under the heading *De Atraphaxi* (*atra*, black, *phaxys*, braid). This name presumably alludes to the “braid” of the fruiting cluster with its black fruits, called by most people the “seeds.”

The first comment on these plants in English was by William Turner ([1548] 1965) who wrote of them, “*Pes anserinus* is called in duch gensz fusz and it may be called in Englishe Goose-fote.” Later, in 1568, he referred to both *Chenopodium* and *Atriplex* as *areche* (we now spell it “orach”).

*Chenopodium album* is native to the Old World (Flora Europaea 2003). Archaeological studies in Canada that identified the species in old Blackfoot sites dated to A.D. 1500 (Tull 1999) cast doubt on whether the species was native or introduced. Unfortunately, Tull did not give a specific reference to her information, and she was no longer able to find her source in her notes (Delena Norris-Tull, personal communication 2003).

There are ample instances of *C. berlandieri* being identified as *C. album* (cf. Hodgson 2001). The question of nativity remains unresolved, but Mary Adair (2003, personal communication 2003) suspects that plants used by the people in the region of the Blackfoot were *C. leptophyllum*. Similarly, King (1984) said that there was no evidence that *C. album* was used by indigenous people. *Chenopodium berlandieri*, on the other hand, is unquestionably native in North America, and was cultivated by indigenous tribes well before Europeans arrived (Smith 1992).

In the Americas, the first mention of what may have been *Chenopodium* was in Virginia by Harriot ([1590] 1972). He wrote in the 1580s: "There is an herbe which in Dutch is called *Melden*. Some of those that I describe it vnto, take it to be a kinde of Orage; it groweth about foure or fiue foot high: of the seede thereof they make a thicke broth, and pottage of a very good taste: of the stalke by burning into ashes they make a kinde of salt earth, wherewithall many vse sometimes to season their brothes; other salte they know not. Wee our selues, vsed the leaues also for potherbes." Later, in speaking of interplanting between hills of maize, he wrote: "By this meanes there is a yard spare ground betwene euery hole [of maize]: where according to discretion here and there, they set as many Beanes and Peaze: in diuers places also the seedes of *Macócqwer* [*Cucurbita*], *Melden* and *Planta Solis* [*Helianthus annuus*]." Harriot ([1590] 1972) also recorded that the seeds were eaten in gruel by the Carolina Algonquians.

Frenchman Antoine Simon Le Page Du Pratz visited Louisiana in the 1720s and witnessed what Gilmore (1931) thought was *Chenopodium* being cultivated. Heiser (1985) rejected that view. Smith (1992) reexamined the account in detail, and came to the same conclusion as Gilmore.

Smith (1992) went to the original French published by Du Pratz in 1758, and discovered that some previous translations were misleading. One of the key segments of Du Pratz's text said, "*J'ai vû les Natchez & autres Naturels sèmer une graine qu'ils nommoient Choupichoul, sur les battures; ce sable n'étoit nullement cultivé, & les femmes & les enfans avel leur pieds couvroient tellement quellement cette graines sans y regarder de près. Après cette semaille, & cette espèce de culture, ils attendoient l'Automne, & recueilloient pour lors une grande quantité de cette graine: ils la préparoient comme du millet, & elle étoit très-bonne à manger. Cette plante est ce qui l'on nomme Belle Dame sauvage, qui vient en tout pays, mats il lui faut une bonne terre; & quelque bonne qualité qu'ait une terre en Europe, elle ne vient que d'un ped & demi de haut; & sur ce sable de Fleuve, sans culture elle s'élève jusqu'à trois peds & demi & quatre peds*" (Du Pratz in Smith 1992). In 1911, John R. Swanton translated this segment. He wrote, "I have seen the Natchez and other natives sow a grain which they call *choupichoul* on these sand banks. This sand is never cultivated and the women and children cover the grain, with a great deal of indifference, with their feet, almost without looking at it. After this sowing and this kind of cultivation they wait until autumn and then gather a great quantity of this grain. They prepare it like millet and it is very good eating. This plant is that which is called "beautiful savage lady" [he footnoted the French *Belle dame salvage*] and which grows in all countries, but it needs a good soil, and however good is the quality of any European soil it there reaches a height of only 1.5 feet, while on this river sand without cultivation it reaches a height of 3.5 to 4 feet" (Swanton in Smith 1992).

Smith (1992) compared etymology, detailed plant and seed morphology, and ecology of today's wild members of *Chenopodium* near the area where Du Pratz made his observations. He concluded that *C. berlandieri* was the species that Du Pratz described. Thus, cultivation of *C. berlandieri* extended into the 1720s and possibly longer into the historical period.

Using "archaeological sites and regions that provide information on agricultural origins," Smith (1992) mapped the range of pre-European distribution of cultivated *C. berlandieri*, and the other Hopwellian cultivars. The seed crop was grown from the

Appalachians west through the Ohio Valley and Mississippi Valley west to the Great Plains between 34° and 40° latitude. This region he dubbed the “interior mid-latitude zone of domestication of native North American seed crops at 2000 to 1000 B.C.” Outside this region, along the Atlantic and Gulf coastal area and across the northern latitudes, Smith (1992) concluded that forager economies were based largely on wild species of animals and plants (except for *Cucurbita* cultivation) until the A.D. 800 to 1100 shift to maize-centered agriculture. Fritz (2000a) has recently given additional details on the agricultural systems of the Mississippi Valley during that period.

Smith (1992) concluded, “Le Page Du Pratz witnessed and described the closing chapter of an agricultural economy that had existed in eastern North America across 4,000 years.” Since Smith’s (1992) publication, an archaeological study by Gardner (1994) has found *C. berlandieri* among historical Caddo in Boissier Parish, Louisiana. The localities in north-western Louisiana were occupied by these neighbors of the Natchez in the 1770s, and include both cultivated and wild types of this chenopod. This is the latest historic record of the herbs being cultivated in the southeast for their edible seeds.

*Chenopodium berlandieri* was cultivated longer in the southwestern United States, and it is still cultivated in Mexico and South America (Smith 1992). Hodgson (2001) found that Cahuilla and Louiseño gathered *Chenopodium* seeds and ground them into flour. The River Pimas (Akimel O’odham) parched and ground the seeds, then ate the flour in *pinole* or combined it with other meal before it was eaten. They stopped growing *kovi* for food in the 1870s when the drought years hit (Rea 1997). The Yavapais collected the infructescences in burden baskets, spread them on a flat surface, and beat them with a stick to separate the seeds. Winnowed seeds were then parched with coals in a basket, ground, boiled, and eaten. The same pattern holds from California, Arizona, and New Mexico south into Mexico.

Southwestern tribes including the Apache, Baja Californians, Cocopa, Mohave, Paiute, Pima, Tarahumara, Tipais, Tohono O’odham, and Yavapais ate the leaves and young shoots. The usual method was to boil and then fry them in grease (Curtin 1949, Ebeling 1987, Hodgson 2001). Rarely did these same people eat the leaves and young stems raw.

People in the southeast did not eat raw plants (Hudson 1976). An exception was *Allium*, but that was an unusual case. Even *Allium* was usually cooked. In the southeast, the few green plant parts that were eaten historically were put in soups and stews (Hudson 1976). More recently, the Cherokee and Muskogean people fried onions, ramps, and other greens before they ate them. Whether they did this before contact with Europeans is not clear.

My own family, going back in my memory to grandparents on both sides, had a marked aversion to raw vegetables. When plant vegetative parts were eaten, it was common practice to fry them, as did the indigenous people of both the southeast and southwest. There was only a short time in the spring when some few vegetables like new lettuce were eaten raw, and even then the lettuce was preferably spread with hot bacon grease (“wilted”) before being consumed.

Europeans discarded *Chenopodium* after spinach (*Spinaca oleracea*) was introduced from Asia about A.D. 1000, although the process took until the mid-1500s (Hedrick 1919, Fernald et al. 1958, Mabberley 1997, Davidson 1999). Some people retained a taste

for it, but *Chenopodium* eventually became regarded as a weed. The chronology of the names tracks the attitude change; fat hen and goosefoot dominated from the time of Pliny to the 1790s. Then, *Chenopodium* still had a “favorable” name of lamb’s quarters from the 1770s to the early 1800s. After the mid-1800s, it became known as dungweed, pigweed, and muck-weed.

The same change occurred in the Americas when maize was brought in from Mexico, and *Chenopodium* of the old Eastern Agricultural Complex declined (Hudson 1976, Smith 1992). Apparently, the records by Harriot ([1590] 1972) and Le Page Du Pratz in the 1720s were the last remnants of generalized *Chenopodium* cultivation witnessed by Europeans in eastern North America.

### *Chimaphila*

(From Greek *cheima*, winter weather, cold, and *philos*, loving, an allusion to the evergreen habit)

***Chimaphila maculata*.** From Britton and Brown 1897.

*amiskwathowipak* (Cree)

*bittergrønn* (bitter greens, Norwegian)

*ga'gige'bug* (everlasting leaf, for *C. umbellata*, Ojibwa)

*i-pi·sara'k* [*surá·k*] (fire grass, Catawba)

*ne-was-char-la-go-ne* (good for colds or coughs, for *C. umbellata*, Osage)

*Winterlieb* (winter loving, German)

***Chimaphila maculata*** (mottled or purpled)

*herbe à clé* [*herbe a clef*] (key herb, Quebec)

*hierba de higado* (liver herb, Mexico)

mountain tea  
 pipsissewa [pipsisseway] (from Cree, *pipisissikweu*, in use by 1789;  
 later recorded in 1814 by Pursh as *sip-si-sewa*)  
 prince's pine [striped prince's pine, prince's flower] (in use by 1891,  
 also applied to *Pinus banksiana*; the allusion is obscure)  
 rats-bane [ratsbane]  
 rheumatism-root (New England)  
 waxflower  
 wintergreen [spotted] (a name applied by the 1540s to plants remaining  
 green all winter, primarily Ericaceae)

The genus *Chimaphila* was created in 1814 by Frederick T. Pursh (1774–1820), a traveler, gardener, and plant collector born in Saxony who settled in Pennsylvania. He published the name in his *Flora Americae Septentrionalis* (North American Flora). Since then, other species have been found and the genus now contains four to five species in Eurasia, and North and tropical America (Mabberley 1997). Northern Europe has a single species, the circumboreal *C. umbellata*, which has been used to treat bladder problems.

The names wintergreen and pipsissewa have been used for a variety of species in *Chimaphila*, *Gaultheria*, and *Pyrola*. For example, “wintergreen” was mentioned in 1542 by Fuchs (*Pyrola rotundifolia*), Turner ([1548] 1965), Parkinson (1640), and in 1653 by Culpepper (*Pyrola minor*). A use for one is likely to be the same as the other.

The Cherokees used *C. maculata* to treat colds, fevers, milk sickness, pain, rheumatism, scrofula, tetter and ringworm, ulcers and “cancers,” and urinary problems. It was also used as an emetic for babies (Hamel and Chiltoskey 1975). The Nanticoke in Delaware used this species against ague (Moerman 1998).

There are many more uses by indigenous groups for *C. umbellata*, and it is likely that *C. maculata* was used in the same ways (Moerman 1998). Hocking (1997) found records of *C. maculata* being used as a diuretic, a urinary antiseptic, to treat rheumatic gout and weak kidneys, as a tonic and alterative, and in cough syrups. He also noted that boiled leaves were a kidney remedy on the Gaspe Peninsula of Quebec.

Physician B.S. Barton recorded in 1810 that he used a strong infusion of wintergreen (*Gaultheria procumbens*), which “evidently possessed of a stimulant and anodyne quality.” He also wrote that it was used by “Indians” (not specified) to treat asthma (Vogel 1970).

Physician F.P. Porcher recorded in 1849 that *C. maculata* was used by the Indians of South Carolina for kidney, scrofulous, and rheumatic problems (Vogel 1970). *Chimaphila maculata* also was recommended for ulcers and skin problems. Hocking (1997) reported that people in Charleston, West Virginia, still use the leaves to treat kidney problems.

*Chimaphila umbellata* contains eriocolin, arbutin, chimaphilin, and tannin (Uphof 1968, Hocking 1997). Presumably, *C. maculata* contains the same compounds.

### ***Chiococca*: Snowberry**

(Patrick Browne immortalized the fruits in Greek with *chion*, snow, *kokkos*, berry)

Throughout the West Indian hardwood forests called hammocks in southern Florida, there are scrambling, woody climbers reaching to the canopy. The leaves on these lianas are distressingly similar to a number of other plants, and there is not much distinctive about them. This is snowberry (Florida) or West Indian snowberry (Bahamas, Puerto Rico) (*Chiococca alba*), and typically, this is the last

***Chiococca alba.*** Drawn by  
P.N.Honychurch.

hammock plant that students learn to recognize. I always tried to help them by telling them in practice sessions that it was a “nondescript, scrambling vine.”

Even Linnaeus and his predecessors had problems with these plants. They did not really know where to put them, and most of the early names put them closer to honeysuckles (Caprifoliaceae) than Rubiaceae, where they are now. Like those before him, Linnaeus first called these *Lonicera* in 1753. Soon afterward, he realized his mistake, and renamed them *C. racemosa* in 1759. However, by international rules, one cannot simply change a name because a mistake was made. So the modern name is the one Linnaeus first gave to the species (*alba*). That species finally was put in the genus *Chiococca* (created by Patrick Browne in 1756) by A.S. Hitchcock in 1893.

*Chiococca alba* is widespread, ranging from southern Florida and southern Texas to the Bahamas, through much of the West Indies, and south from Baja California, Sonora, and Tamaulipas, to Peru, Brazil, and Argentina.

Several of the common names of *C. alba* refer to animals, although for different reasons. For example, they are associated with pigs as in *bejuco de berac* (pig vine, Puerto Rico), *bejuco de berraco* [verraco] (pig vine, Cuba, Puerto Rico), and *raiz de verraco* (pig root, Cuba). Those common names are probably associated with the odor of the stem when cut and peeled. Others think the odor is more like that of a skunk. The Maya call the scrambling shrubs *pay-che'* [pax-che] (skunk tree, Belize). Because of the Mayan word construction, the name may also be given because the plant's dark leaves and white fruits reminded them of the mammal, or both reasons. Spanish speakers say it is a *zorillo* (little skunk, Belize), and English speakers in the same area say skunk root.

In addition, the species is compared to a mouse as in *croc souris* (mouse-colored hook, Hispaniola) and *oreja de ratón* (mouse's ear, Sonora, Yucatan), or a rat with "man rat root" (Bahamas), and "rat-bush" (Bahamas). It is even compared to a bat with *raiz de murciélagos* (bat root, Colombia). Perhaps these too refer to the foul odor of the cut stem, as each of these mammals has a distinctive smell.

One of the old names for the vines that is rarely heard now in Florida is snakeroot (Bahamas, Florida). That, and the Brazilian translation, *raiz de serpentária*, made no sense until I finally discovered the etymology of the most widespread name applied to these plants. That name is *canica* (Texas, Cuba, Mexico). Variants of this name occur as far south as Brazil, with *caimica* (Columbia), *cainana* (Brazil), *cainca* [*cainca*] (Brazil), *cainica* (Columbia), *casinga* [*caringa*] (Brazil), the *casinga cheirosa* (fragrant, *casinga* is the medicinal *Laetia suaveolens*, Flacourtiaceae), *quimaque* (Hispaniola), and finally *caninana* (Mexico, Brazil). These made sense only after determining that *caninana* is based on the Tupí word *ñakani'nã* (head by your foot), and refers to the snake *Spilotes pullatus*, a colubrid. Probably, without knowing the meaning, people carried that name throughout the New World wherever these plants grew. The variant *canica* resembles both Náhuatl (*canin*) and Otomí words (*caní*, herb), but presumably is unrelated to either. Morton records the name falsa *canica* (false canica) but does not give the region of its use. Although the spelling is markedly different, I suspect that *timaque* [*timacle*] (Hispaniola) and *bejuco timaque* [*timacle*] (timaque vine, Hispaniola) are cognates to *canica*.

Other common names make other comparisons. In Barbados they are briny roots, presumably in reference to taste. Brazilians think the somewhat square stems resemble a cross and call them *cipó cruz* (cross vine) or *cruzeirinha* (little cross). Martin Sessé and José Moçino, two Spanish explorers in the 18th century, called the vines *perlilla* (little pearl). Either that name was misunderstood or it has changed, because they are now called *perilla* (pear-shaped lobe, Nicaragua, Peru, Mexico). Either way, the names refer to the white fruits. Also alluding to the fruits is the name *acetillo* (little sour one, El Salvador).

The only reasons that seem to exist for comparing these vines to heaths (Ericaceae) is that both are medicinal, and both have somewhat tubular flowers. Yet, the comparison is made with *bois branda* (heather bush, Guadeloupe, Martinique) and *petit branda* [*ti branda*] (little heather, Guadeloupe).

Comparisons to *Jasminum* (Oleaceae) indicate that the flowers are fragrant at night for moth pollination. Those names include *jasmín bâtard* (false jasmine), and *jasmin bois* (jasmine bush, Guadeloupe, Martinique). In the Creole French of the islands, *bois* (literally tree) means "herb," with a medical connotation. Another suggestion of nocturnal fragrance is *dama de noche de pine ridge* (Pine Ridge lady of the night, Belize).

Several of the names make specific reference to the roots, one of the preferred medicinal parts. These are *purga preta* (black purge, Brazil), *quina de raiz preta* (black-rooted quinine, Brazil), *racine noire* (black root, French Antilles), and *raiz preta* (black root, Brazil).

Virtually all of the other common names refer directly or indirectly to medical usage. David's milkberry (Texas), David's root (Commerce), and milkberry (Texas) allude to previous commercial use of the herbal medicine in the United States and Europe. In those

pharmacopoeias the root bark was also known as *Radix Caincae*. Other names that refer to use as a medicine include *cuanecatashich* (*cuana*, remedy, Zapotec, Hidalgo), *damburé* (apparently a malady, Brazil), *lágrimas de María* (Mary's tears, Panama), *lágrimas de San Pedro* (Saint Peter's tears, El Salvador), *liane de sorciers* (sorcerer's vine, French Antilles), *madreselva* (mother of the forest, Nicaragua), *madreselva de las Antillas* (Antillean mother of the forest), *pegajoso* (easily caught, Sinaloa), pissabed (Bahamas), *poaia* (from *pu'aya*, ipecac, an emetic, Tupi, Brazil), *raiz de frade* (brother's [ecclesiastical] root, Brazil), *raiz de quina* (quinine root, Brazil), *suelda con suelda* (money-with-money, Yucatan, Cuba), tim-tom bush (Barbados), *tori naca* (Mayo, Sonora), and *x-kanchakche'* [*xcanchac-che'*, *canchacche'*, *kanchak-che'*] (*ka'an*, yellow and *chak*, red, *che'*, tree, in reference to the wood, Yucatan, Maya).

The medicine from different parts of the snowberry is considered acrid, tonic, astringent, vomitive, and pectoral. It is said to be anti-asthmatic, antihydrotic, diuretic, emmenagogue, emollient, febrifuge, hydragogue, and a purgative. It has been used against ailments including alcoholism, colitis, constipation, delayed menstruation, dementia, depression, dropsy, dysentery, edema, endometriosis, lymphatic system disorders, nervousness, and pain. It is used to expel gas, ease menstrual cramps, as an aphrodisiac, to cure sores, rashes, and ulcers, for snakebite, to dispel witchcraft and evil eye, to treat ulcers of the stomach or intestines, and against venereal diseases (Roig 1945, Morton 1981, Arvigo and Balick 1993, Vásquez and Jácome 1997, Mors et al. 2000).

Most users are quick to point out that this is a strong remedy and not to be taken internally by the elderly and very weak (Arvigo and Balick 1993). Preparations vary depending on the problem being treated, but roots are most often used internally (Mors et al. 2000). Boiling the roots produces a liquid that is ingested alone, or it may be prepared with other plants added. For example, the roots are boiled with *Picramnia pentandra* to treat gas and relieve menstrual cramps (Morton 1981). Flowers are emollient and are used to treat skin diseases.

One of the most interesting remedies is to inhibit alcoholics from drinking (Arvigo and Balick 1993). The method is to place one handful of chopped root in 1 quart of rum, vodka, or gin. This mixture is soaked in the sun for 5 days and strained. People seeking the cure should take one shot of this daily until the mixture is gone, or finish it all at once. Apparently, they will vomit violently after each drinking session, and after that the smell of alcohol will make them nauseous for years.

The plants are loaded with chemicals. Compounds identified include coumarins, alkanes, carbohydrates, lignans (El-Hafiz et al. 1991), cardiogenic glycosides, saponins, tannins, flavonoids (Schapoval et al. 1983), alkaloids (El Abbadi et al. 1989), and a triterpene (Bhattacharyya and Cunha 1992). An alcohol extract of dried leaves showed *in vitro* cytotoxic activity against cancer (65% inhibition). Stem extracts showed 77% inhibition, while roots gave 69.6% (Nascimento et al. 1990).

If you move into the pinewoods, there is another plant that resembles snowberry. This one, however, has smaller fruits and slightly darker flowers. That plant is *Chiococca parviflora*, which Wunderlin (1998) lists as synonymy of *C. alba*. Although opinions have varied over the years, elsewhere in the tropics others retain them as distinct. Roots of this species have been used to treat tuberculosis and bed-wetting in children. Much less is known about this species, but medicinally it may be similar to *C. alba*. Both of

these species have been used medicinally, and the information on one is perhaps applicable to both. Some people, like some taxonomists, may not separate them.

### *Chionanthus*

(From Greek *chion*, snow, and *anthos*, flower; alluding to the snow-white flower clusters)

#### *Chionanthus virginicus* (of Virginia)

flowering ash; poison ash (a name used for *Rhus vernix* by 1760; the result of confusion with *Chionanthus*, as by Porcher in 1863); white ash (the name usually given to *Fraxinus americana*)

#### *Chionanthus virginicus*. From Sargent 1905.

[American, white] fringe [tree, fringe-tree] (probably first used by Mark Catesby in 1731)

fringe-flower (in use by 1882, when John Smith wrote the name in his *Dictionary of Popular Plant Names*); fringe-tree (in use by 1730); white fringe tree (used by Williams [1837] 1962)

Grancy graybeard; granddaddy's beard; graybeard [tree] (first applied for the lichen *Usnea barbata* by 1599; later extended to the tree)

*hataks pone nepakwibe* (*hatak*, man, Choctaw)

*nita imilipa* (*nita*, bear, *im*, its, *ilpa*, food, Alabama); *nitá infakakcô* (*nitá*, bear, *im*, its, *infakakcô*, swamp privet, *Viburnum rufidulum*, Kosasti)

old man's beard (recorded for *Clematis* in 1542; later for *Tillandsia usneoides* by Patrick Brown for Jamaican plants in 1756; later applied to a number of plants including *Saxifraga* and *Chionanthus*)

privet tree (misapplication of the name for *Ligustrum* by John Brickell in 1737, although they are in the same family)

shavings (application obscure unless possibly the stems were used for handles of shaving brushes)

snow-drop tree [snow-drop-tree, snowdrop tree] (by 1731 when Philip Miller used it in his *Gardeners Dictionary*)

snow-flower(s) [snowflower(s), -tree] (snow-flower was used by 1664, probably for *Galanthus* as a commentary on medieval earring fashions,

not weather; by 1862 applied to *Hepatica*; finally, in 1862 it was being used for *Chionanthus*, with or without the suffix -tree)

Probably the first record of *Chionanthus* in Europe was the appendix written by London apothecary James Petiver in John Ray's *Historia plantarum* (History of Plants) in 1704. Petiver was an avid collector of plants from around the world, but he kept virtually no records of where they came from or when he got them. Therefore, the specimen that is now in the Linnaean herbarium has no provenance information.

Mark Catesby illustrated the plants in 1731, and Linnaeus studied them in cultivation at the *Hortus Cliffortianus* in 1738. Only a year later, Adrian van Royen listed the species being grown in Leiden. There is small wonder that the plants were spread so quickly as they are breathtaking when in flower. Catesby used the name "fringe tree" in 1731.

The Choctaw boiled the bark and used the extracts to bathe wounds. They also used the mashed bark as a poultice on cuts and bruises (Bushnell 1908). The Alabama and Koasati used the bark to treat toothache, and the Koasati used it on cuts and bruises like their relatives the Choctaw (Taylor 1940).

Rafinesque (1830) thought the roots made a cataplasm that would heal wounds without infection. Porcher (1863) wrote: "An infusion of the roots is given in long standing intermittents. It is tonic and febrifugal, with some acro-narcotic properties; used in the form of cataplasm as an application to wounds and ulcers." Millspaugh (1892) too was enthusiastic about the medical properties of the plants. He wrote: "The previous use of the bark of this shrub as an astringent vulnerary, and the bark of the root as a tonic after long and exhaustive diseases, is one that has a great merit. The bark in infusion is a remedy that was too long often neglected for foreign drugs."

Krochmal (1968) and Krochmal and Krochmal (1973) noted that the Appalachian pioneers applied a poultice to cuts and bruises. Leaves and flowers were used to treat inflammations and sores, ulcers in the mouth and throat, and diarrhea. Hocking (1997) considered the plant an alternative, bitter tonic, for use against liver problems, as a stimulant, and in controlling fevers. However, Foster and Duke (1990) warn that overdoses cause vomiting, frontal headaches, and slow pulse.

The best-known active chemicals in the plants are chionanthin and tannins (Hocking 1997). Duke et al. (2001) are not as enthusiastic as was Millspaugh (1892). They give the remedy a single plus (not as safe as a cup of coffee).

### ***Chromolaena*: Bitter-bush**

(From Greek *chroma*, color, and *chlaena*, cloak or blanket, perhaps referring to the bracts)

Along roads and trails, especially in the Florida Keys, there is often a mass of green sprawling over other plants. Near Christmas, the white to pale pink or blue flowers of this herb paint the landscape. These flowers are visited by a number of bees and flies and make the area buzz with life. Some people call the herb bitter-bush (Florida, Jamaica, Trinidad, Puerto Rico). Many of those who have immigrated from the Caribbean call it Christmas bush (Jamaica, Virgin Islands, Trinidad), Christmas rose, *fleurit-Noël* (Christmas flower, Guadeloupe, Martinique), or *flewí nwel* (Christmas flower, Trinidad).

A variety of different Florida plant species blooming near the end of the year are called Christmas flowers.

Opinion is divided about what the scientific name should be for this sprawling herb, as it has been since Linnaeus described *Eupatorium odoratum* in 1759. Some retain it in that genus, while others say that grouping is artificial and segregate this and 164 other species into another genus. They call *Chromolaena odorata* bitter-bush. Indeed, *Chromolaena* was created in 1836 by Swiss botanist Augustin-Pyramus de Candolle (1778–1841), but the specialists in the Asteraceae have not agreed about generic delimitation. Still, with added information views change, and the trend now is to accept the isolation of *Chromolaena* (King and Robinson 1987).

The name *Chromolaena* is often interpreted as referring to the bracts. Some think that instead the name alludes to the tendency of the herbs to smother other vegetation, and many of the common names support that view. The old name *Eupatorium* was in remembrance of Mithridates Eupator, the ancient king of Pontus, who used plants of this genus for preparing medicines. Among those who use the plants as cures, *Eupatorium* would have been a more appropriate term. The name *cihuapatli* [*ciguapazle*, *cihuapastle*, *ciguapaztle*] (*cihua*, woman, *path*, medicine, Náhuatl, San Luis Potosí) notes its use by women. That name is also applied to *Montanoa tomentosa*, another medicinal composite. The specific name *odoratum* refers to the fragrance given off by the leaves. That fragrance almost guarantees that people will have uses for the plant. Perhaps the common names paraffinweed, paraffinbush, turpentine weed, *varejón de caballo* (horse's [wild] sage, Colombia), and vanilla (Jamaica) also note the fragrance.

Bitter-bush was restricted mostly to the Florida Keys for many years and then, as the area was developed, it spread through more of the peninsula. *Chromolaena odorata* also is known from the Bahamas, the West Indies, Mexico (almost all states), and south to Argentina and Paraguay (Solomon 2002). Comparatively recently, it was introduced into the Old World tropics where it is a weed of croplands and forests (Cruttwell-McFadyen 1989, Rouw 1991, Peng and Yang 1998). Presumably, confusion about the origin of the plants led to the common name Siam weed.

Although these large herbs were in Florida before Europeans settled there, comparatively few residents have names for them. That is not true outside Florida, where many people recognize them. There are two primary categories of common names for the plants, with a third that is an uncertain collection.

Many people know the plants as medicines. Those having this information often note the cross that the leaves and stems make, and some take this as an emblem of the Holy Cross. These people call the herbs *crucetillo* (little cross, Oaxaca), *crucita* [*crucito*, *cruzeta*] (little cross, Jamaica, Texas, San Luis Potosí, Trinidad), *crucita oleroso* (fragrant little cross, Nicaragua), *cruz-de-campo* (wild cross, Brazil), *cruz-quem* (whose cross, Brazil), *cruzeiro* (cross, Brazil), *curarina* (little curer), and *curarina de monte* (wild little curer). Other names making holy references are *Santa María* (Saint Mary, Puerto Rico) and *caraquillo Santa María* (Saint Mary's *caraquillo*, Puerto Rico). The reference to *caraquillo* is to *Lantana camara*, and it is probably the same as in the name *alba-haquilla* (white *haquilla*, Cuba). Perhaps it is based on some Arawak word. Archangel (Jamaica, Trinidad) is surely another of these holy references. Perhaps kingsweed also belongs in this grouping. In Veracruz, it is called *krus tok'te* (cross *tok'te* which compares it to *E. albicaule*, Huastec).

The basis for some of the medicinal names is obvious, while for others it is obscure. For example, *langue à chat* [*langue chatte*, *langa chata*, *langi-chatte*] (cat tongue, Hispaniola, French Antilles) refers to the rough leaves. More obvious is *mejorana* (makes it better). The Cuban *filagrana* [*filagrama*] *de sabana* (savanna filigree) is an allusion to *Lantana camara*, a notorious medicinal plant. The more widespread *rompe-zaragüey* (shoe breaker, the same name given to *Vernonia menthaefolia*, Cuba, Hispaniola) and *zaragüey* (shoe, Hispaniola) presumably denote the curing of medical problems. The name hemp agrimony (Jamaica, Trinidad) compares it with agrimony (*Agrimonia*, which see), a well-known herbal medicine. In Panama, it is *paleca*, which may be a reference to *palco*, a mouth sore found in children.

In Cuba and Venezuela, some call it *chimuyo* [*chimojo*], a reference to *chimó*, a mixture of tobacco and lime that is chewed. Whether or not the mixture is considered medicinal depends on the viewpoint. If one is a field hand working in the hot sun with little food, it might seem like medicine against pain.

The remaining references are unknown: Armstrong's weed, Jack-in-the-bush [Jackney-bush, and Jack-in-bush] (Belize, Jamiaca, Trinidad), and *zanca de grullo* (crane's stilts, Cuba).

As a medicine, the plant has been used in various ways (Standley 1920–1926, Roig 1945, Martínez 1969, Liogier 1974, Petersen 1974, Morton 1981, Arvigo and Balick 1993). In several places, flowers are made into a tea used against coughs and diabetes. Leaf decoctions are considered a remedy for colds and coughs in at least Barbados, Belize, Panama, and Trinidad. In Jamaica the plant is used the same way, but mixed with other plants.

Internally, the medicine from bitter-bush has been used by the Maya of Yucatan against stomachache and kidney trouble. Guatemalans consider the bitter root tonic and use it against stomach problems. Other people in Mexico once used it against malaria, as an emmenagogue, and to treat gonorrhea. In Belize and Hispaniola, the tea is considered good for calming the nerves and to alleviate laryngitis, insomnia, and depression. In Jamaica, Cuba, the Virgin Islands, Barbados, and Belize it is used externally to treat fever, and in baths for skin diseases. Crushed leaves are even put on cuts to help them heal. There is a known anticoagulant property to the plants (Mabberley 1997).

The plants contain a number of toxic compounds, which is common for all medicines. Some of these compounds are so potent that the plant has been used as a fish poison. The species contains ceryl alcohol,  $\beta$ -sitosterol, aromatic acids, the flavone isosakuranetin, chalcone (odoratin), sesquiterpene alcohol (eupatol), trihydric alcohol, anisic acid, terpene alcohols (lupeol,  $\beta$ -amyrin), and flavone (salvigenin) (Baruah et al. 1978, 1993, El-Sayed et al. 1988, Her et al. 1994, Irobi 1997, Morton 1981, Nguyen et al. 1992, Wollenweber et al. 1995, Wollenweber and Roitman 1996).

Antibacterial activity of dried leaves and stems has been demonstrated against *Bacillus subtilis*. Dried leaves have a coagulant activity in rats and decreased prothrombin time. Fresh leaf extracts have antifungal activity against *Rhizopus* and *Ustilago maydis*. Leaf essential oils are antibacterial against *B. subtilis*, *Escherichia coli*, *Klebsiella acrogenes*, *Staphylococcus aureus* (Arvigo and Balick 1993), and a number of other microorganisms (Gupta 1995a).

The only reference to the plants being used as food may be from Venezuela (Pittier 1926). There they call it *pesebrito*. A *pesebre* is a manger for feeding animals. Perhaps

the people there use the rampant growth of greens as fodder for animals, although that seems doubtful. The plants are known to be toxic to some types of livestock (Mabberley 1997, Apori et al. 2000).

Those who hate the plants have a number of pejoratives for it. One of the derogatory things one might do is compare it with a blood-sucking ectoparasite, which is done by calling it a *garrapata* (tick, Nicaragua). People who have pulled it from their cultivated fields call it *guér it-tout* (conquers all, Hispaniola, Guadeloupe, Martinique), *guérit-trop vite* (conquers all life, Guadeloupe, Martinique), *guérit-vite* (conquers life, Hispaniola), *mata finca* (farm killer, Hispaniola), *rey del todo* (king of everything), *suplicio* (torture, an allusion to covering everything), and *tokabal* [*tocaban*, *x-tokabal*, *xtok'aban*] (plumb thief, Maya, Yucatán). That Mayan name is given because this is a frequent weed in groves of *ciruela* (*Spondias monbin*, Anacardiaceae). When allowed to grow below the trees, there is a marked decrease in the number of fruits produced. The Maya knew the allelopathic effects on maize long before they were discovered by others (Oguntimein and Elakovich 1991).

Meanings or references for the following names are obscure. The herbs are called *kluset* (Creole French, Trinidad), *niquibey* (probably Taino, Hispaniola), *sich* (Tzeltal Maya, Chiapas), tonka bean (Jamaica), triffid weed, *tsitsaque-teutzushu* (Totonac, Veracruz), and *yaxhatz* [*hotz*] (Belize).

In a deliciously ironic twist, these medicinal and poisonous plants are now providing another useful service in areas where they are not native (Holm 1991). Someone had the idea that they might provide good “green manure” under crops of black pepper (*Piper nigrum*). The side benefit is that they also deter a roundworm pest (*Heterodermarion*) of black pepper and the root-rot fungi (*Pythium complectans* or *P. splendens*).

### ***Chrysobalanus*: Coco-Plum**

(Based on the Greek, *chrysos*, golden, and *balanos*, acorn or glans penis)

***Chrysobalanus icaco*. Drawn by  
P.N.Honychurch.**

In areas where the beach is still intact in Florida, one occasionally finds a small shrub with dark green, egg-shaped leaves. There is a definite rosaceous look about the plants although technically they are not in that family. If you visit during the right season, you find drupes about the size of a quarter. The fruits are distinctive of the coco-plum, and come in several colors: white, yellow, red, or purple. If you go inland from the beach, you find the same kinds of plants in hammocks, on the edges of wetlands, and scattered throughout the Everglades. As the water table has been lowered by urbanization and “flood control” the shrubs have become more abundant than they were formerly.

Although the name coco-plum sounds like there should be some resemblance to the coconut (*Cocos nucifera*), there is no relationship between the names. The resemblance is a case of convergence in totally different languages to words that are spelled and pronounced the same (homonyms).

While this species was recorded by Fernández de Oviedo y Valdes Gonzalo (1478–1557) in the 1500s, it first became known to most Europeans when Hans Sloane published his study of Jamaican plants in 1696. Sloane called them *Myrobalanus minor*, *folio fraxini alato*, *fructo purpureo* (small perfumed acorn, with leaves winged like the ash, and purple fruits), but he pointed out that there were yellow-colored variations (...*fructo luteo*).

It was not until 1703 when Charles Plumier (1646–1704) told Europeans that the indigenous name for these plants in Haiti was *icaco*. However, Spanish explorers had long known the name because Barrientos (1567) reported that Menéndez and his men were forced to gather and eat “*cacos*” during their short war against the French Huguenots in 1565. That common name was so similar in languages from Florida to Venezuela that eventually it too became part of English. Linnaeus used Plumier’s information to give it its specific name. This shrub or small tree’s scientific name is *Chrysobalanus icaco*, applied by Linnaeus in 1753.

Most texts translate *Chrysobalanus* as the golden acorn. However, true to his personality, Linnaeus had selected a Greek word with a dual meaning. *Balanos* means an acorn, but it also refers to the glans penis of the male reproductive organ. It was not an accident that Linnaeus also applied the same word to the barnacle, *Balanus*.

The specific name taken from Plumier’s report on the island of Hispaniola included the indigenous name for the plants there in Taino. *Hicaco* [*icaco*, *jicaco*] was the word for the plants in Hispaniola, and there are variants in the languages spoken from Florida to Venezuela and Colombia. The Seminoles of Florida call the plants *hekako* [*hiká:ko*] (Creek) and *hiká:kî* (Mikasuki). Probably, this is the *tococo* (eat new fruit) of the Timucua. In Mexico and Central America there are variations including *caco* (Chiapas), *gicaco*, *hicaco*, *higágu* (Garífuna, Nicaragua), *icaco* (Cuna, Panama), *icaque*, *icaquier*, *jicaco*, *jicaquillo*, *xicaco* (Oaxaca), and *zicaque* (from Tamaulipas and Guerrero, Mexico, to Honduras). Surely *ka-ka-tà* (Belize) is a variation of the same name.

“Coco-plum” is used in the Bahamas as well as Florida. In the Caribbean it is *ecacs* or *ekaakes* (Aruba, Bonaire, Curaçao), *hicaco* [*jicaco*] plum (Belize), *icaco de costa* (coastal coco plum), *icaco de playa* (beach coco plum), *icaco dulce* (sweet coco plum), *kocho-rhum* (Belize), *prunier icaque* (coco plum tree), *zikak* (Trinidad), or *z’icaque* (Dominica). It may be that *uichup* (Cuna, Panama) is cognate to these names.

There are other names in different languages. To the Zapotecs of Oaxaca, Mexico, it is *nocuana bebebe* [*nocuana pebebe*, *nocuana be-bee*] (*nocuana*, edible herb, *bebebe*,

fruit), *pe-pepe niza-tao-pani* (seaside fruit), or simply *pepe* [*pe-pepe*] (fruit). Other people think it is more like a plum or prune, and it is *ciruelo de algodón* (cotton plum), *prune-coton* (cottony plum), *ciruelo de paloma* (dove plum, Yucatán), *prune de guyane* (Guyana plum, French Guiana), *prune de l'anse* (cove plum, French Guiana), or simply *pruim* (plum, Suriname). Although the name is usually given to *Coccoloba*, it is also known as pigeon plum (Guyana). My favorites are “fat pork” (Bahamas to Guyana) and “pork-fat apple” (Bahamas). The name fat pork is not pronounced as we would in the United States, but rendered “fat poke.”

With the shift of dominant indigenous languages in Brazil, the name becomes *abajeru* (from Tupí *waye' rá*, apparently formerly *Chrysophyllum*, Sapotaceae, Amazonas, Pará). Variations on this name include *ariu*, *ajurú*, *abagerú*, *guajuru*, *guagerú*, and *uajurú*. In Guyana and Suriname, the name is *kurimiru* [*caramio*, *koelimiro*, *kulimiro*], which is Arawak (Klooster et al. 2003).

The most widespread use of this plant is as food. The common name typically refers to the fruit. Fruits are consumed in several ways. Perhaps the most common form is fresh, directly from the plant. Fruits may also be canned or made into jam or jelly. According to some, the fruits are improved by soaking overnight and then peeling and stewing with sugar. Some even pierce them through the kernel before doing that because the seed is edible along with the pulp. Moreover, they were formerly the basis of businesses in Cuba, Brazil, and Costa Rica where they were canned and exported (Morton 1968b).

Students in my classes over the years were not always overly impressed with the flavor of the fruits. They gave a number of comparisons to the slightly sweet pulp of the fruit, but the one I favored was that it tasted like “sweetened cotton.”

Most who are familiar with the fruits know that eating the pulp from around the seed is only the first step. Breaking open the seed coat exposes the kernel within. This is edible raw or toasted, and it tastes somewhat like almonds. In Brazil, the oil from the kernel has been substituted for almond oil in medical ointments (Morton 1981).

Less known in the United States is that the seeds contain enough oil that they may be strung on sticks and burned like candles (Morton 1981). They were the original torches of the regions where they grew. Not only do the seeds produce light, but the oils also have been used to make candles, soap, axle grease, and other similar products. These kernels, along with the leaves, create a black dye. Along the Amazon, the kernels are used to dye fishing nets to make them resistant to decay (LeCointe 1947).

Oil in the seeds may be 20 to 22% by volume. The kernel contains palmitic acid, stearic acid, archidic acid, conjugated octadecadienoic acid, alpha-eleostearic acid, alpha-parinaric acid, alpha-licanic acid, and 4-oxooctadeca-cis-0, *trans*-11, *trans*-13, *cis*-15-tetraenoic acid.

Among the Seminoles, the plant is called *hika:ka: pi* (hikako, *apí*, tree, Mikasuki). The fruit is *hika:kí* [*hekaake*, *hikaaki*] (Mikasuki) or *hika:ko* (Creek). They considered them a source of food (fruits), arrows, and medicine (Sturtevant 1955, Bennett 1997). Indeed, the Seminoles used coco-plum in a medicine to remake a person through *aknoksahkí*. In situations where a person gossips too much, or whose presence makes other people no longer want that person around, a “cleansing” is needed. This cleaning is not just washing the outside of the body, but using a treatment that cleans the whole person. If the job is done correctly, everyone will like the person better. Logs are cut a specific size from live oak (*Quercus virginiana*), willow oak (*Q. laurifolia*), *mastic* (*Sideroxylon foetidissimum*),

satinleaf (*Chrysophyllum oliviforme*), coco-plum (*Chrysobalanus icaco*), and wax myrtle (*Myrica cerifera*). The logs are burned and the ashes boiled. After a particular song is sung over the medicine to bless it and make it potent, some is put on the patient's tongue. Then he or she bathes in cold water. The patient may not eat in the morning after taking the cure, but may either eat at noon or fast all day. Another bath is taken with specially prepared mud from a crawfish chimney, and then the patient returns to camp. The treatment is finished and the person should behave differently and be viewed differently by those around him or her.

Throughout its range, *C. icaco* is considered medicinal by all who know it (LeCointe 1947, Morton 1981, Mors et al. 2000). The bark and leaves are high in tannin and therefore astringent. One of the primary uses is to treat dysentery. For example, in Trinidad, a decoction of bark and roots is used to treat that problem. In El Salvador and Brazil, an infusion of fruits, leaves, and bark or roots in boiling water is taken to treat diarrhea.

In Brazil and elsewhere, the bark is considered antidiabetic. Roots, bark, and flowers are used against chronic diarrhea, blennorrhagia, leukorrhea, and bladder problems. The mixture of boiled leaves and bark or roots is also used to treat hemorrhages. In Costa Rica, a bark infusion is drunk to relieve kidney problems.

Tea from the leaves produces hypoglycemia in mice and protects against lethal doses of alloxane. The tea also inhibits intestinal absorption of glucose and controls blood sugar levels in type II diabetes.

### *Chrysophyllum*: Satinleaf

(Greek, *chrysos*, gold, *phyllon*, leaf)

*Chrysophyllum oliviforme*. a. Flowering branch, b. Leaf outline

showing venation. c. Flower, side view. d. Flower, from above, e. Flower, longitudinally dissected, f. Floral diagram, g. Branch with fruits. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

Before urbanization, there was an almost continuous West Indian forest along the southeastern Florida coast extending from at least Miami to West Palm Beach. Scattered through this forest were small trees with leathery leaves that are dark green above and satiny brown below. When the wind blew across these forests, they glistened like the gold that the Spanish *conquistadores* sought because of the exposed undersides of the leaves. The trees are satinleaf (Florida, the Bahamas, Puerto Rico), *Chrysophyllum oliviforme*.

By the time I arrived in Florida in 1970, most of the forests had been replaced by housing, and the few remaining fragment hammocks were devoid of the satinleaf in Martin, Palm Beach, and Broward Counties. In Miami-Dade County, there are still places where the trees persist. Moreover, on many of the tree islands in the Everglades and Big Cypress Swamp region, the trees remain. Sometimes their leaves can be seen from a distance as you approach those hammocks, and it is always an adrenalin boost to see this comparatively rare tropical plant.

Satinleaf is essentially circum-Caribbean, and is found in Florida, the Bahamas, Cuba, Hispaniola, Puerto Rico, Jamaica, Chiapas, San Luis Potosí, Oaxaca, Yucatán, Belize, Honduras, and Panama. It belongs in the genus *Chrysophyllum* with about 40 other species (Mabberley 1997). Some 15 or so species are confined to Africa, about 10 occur in Madagascar, and 2 or 3 grow from Indomalesia to Australia. All the others are American.

The satiny covering on the lower surface of the leaves is surely the source of the English common name. However, speakers of other languages and those deeper in the tropics use common names that have nothing to do with the leaves. The Seminoles call them *hilókwa inlokí:yaca:kitâ* (Creek) or *hacalo:pí:há: yickí:kí* (Mikasuki). Sturtevant (1955) translated both words to mean “to chew strangler fig berries.” However, that does not seem to be literal. The Creek is based on *helokwv*, chewing gum, *enlowake*, bud, and *yvaketv*, chew (Martin and Mauldin 2000). The small, black fruits are chewy, sweet, and gummy, and have been used by the Seminoles and others as “chewing gum.” They are edible, but you are forced to chew them an inordinately long time before you feel comfortable swallowing them. A related name is the Mexican *chicle de monte* (wild chewing gum, Chiapas).

A large variety of birds and mammals consume the fruits and spread them. It is largely because of animal dispersal that the seedlings appear in distant tree islands across southern Florida. The same occurs outside Florida where they are eaten by more tropical animals. In the Yucatán peninsula of Mexico, the Maya call the trees *chi'ik die* [*chikeh*] (coati tree). There the *tejon* or *coatimundi* (*Nasua narica yucatanica*) not only eat the fruits, but also make their temporary nests in the tree branches.

The leaves and the fruits are similar to a related species from deeper in the tropics that has long been a favorite. That is the *caimito* (*C. cainito*). Although the word *caimito* was

adapted by the Spanish from the Taino word in Hispaniola, it is now used and understood throughout Spanish-speaking Latin America.

The *caimito* was the first species that became known to Europeans. That name appeared first in 1633 in a book by Jan de Laët entitled *Novus orbis, seu Descriptionis Indiae occidentalis...* (The New World, or Description of the West Indies...). At first, people in Europe did not know what to do with this strange fruit. Hans Sloane thought it was more like a pond apple and called it *Annona foliis subtus ferrugineis, fructu rotundo majore laevi purpureo* (*Annona* with leaves rusty below, and having a large somewhat purple round fruit). Linnaeus capitalized on the leaves being reddish below and coined the genus *Chrysophyllum* in 1753. He did not learn about the satinleaf until later and named it in 1759 when he published *Systema Naturae*.

Many of the common names for the satinleaf have references to its relative *caimito*, usually called star apple in English. For example, *caimitillo* [*cayumito*] (little caimito, Chiapas, Cuba, Dominican Republic), *caimito* (from Haitian Taino, Caribbean, Oaxaca, Honduras), *caimito cimarrón* [*cayumito silvestre*] (wild caimito, Chiapas, Cuba), *caimito de perro* (dog [wild] caimito, Hispaniola), wild star apple (Belize, Jamaica), *zapote caimito* (caimito zapote, Oaxaca), and *zapotillo* (little zapote, Mexico). In those names referring to *zapote*, the speakers are using a Náhuatl word, *zapotli*, meaning “sweet fruit.”

Two instances of apparent misidentification are recorded with *canela* (cinnamon, Oaxaca), and *palo de canela* (cinnamon tree, Oaxaca). If misidentification is not involved, the application of *canela* is broader than has been found elsewhere.

Two of the common names compare the fruits to others. In Belize *C. oliviforme* is called damsel, and elsewhere damson-plum. That name compares it with the “true” damson plum (*Prunus ×domestica* ssp. *institia*). The comparison with damson is apparently because both are small acid purple fruits. The tastes of the two surely cannot be compared. In the Bahamas the people call it saffron-tree. The comparison with saffron (*Crocus sativus*) is uncertain unless it refers to the color of the leaf undersides.

Some names make other allusions. The comparison between the fruit and a mammary gland is clear in *teta de burro* (burro’s tit, Puerto Rico). Exactly what is meant by *quebracoyol* (*quebra*, break, *coyol*, a nut-bearing tree, Náhuatl, Chiapas) is not obvious. However, this may be another allusion to testes. Finally, *ocatlán* (place of *ocatl*, Náhuatl, San Luis Potosí) has the typical Náhuatl ending meaning place, *-tlán*. Unfortunately, no translation has been found of the first part of the word unless it might be transcribed as *ocotl*, which means pine resin. Any connection between pines or resins and *Chrysophyllum* is abstruse. *Thijul* [*thituy*] has been recorded as the name used by the Huastec of San Luis Potosí. That seems to be a variant of their name *thiiw*, for *C. mexicanum*, which is not translatable. Either the names are the same for both species, or there is some slight orthographic variation.

The remaining names all appear to be untranslatable and are perhaps simply the indigenous phonemes for the species. These include *chijilté* (Chiapas), *chuni* (Chiapas), *isi* (San Luis Potosí), *nensarrajo* (Choco, Panama), *pacuschumí* [*pascuschuni*] (Chiapas), *pipa* (Cuna, Panama), and *tuko* (Choco, Panama).

As with many other members of *Chrysophyllum*, the fruits are not large, and they are especially favored by children. The wood of all is valued. According to Liogier (1974), the wood of satinleaf is hard and difficult to work. Still, it is used for posts and rafters, and it is made into charcoal. Leaf decoctions are used to heal infected contusions. This is

also one of the species that the Miccosukee use in a medicine to “cleanse” a person (see *Chrysobalanus*: Coco-Plum, for details). Comparatively little seems to be known about this species, but saponins, coumarins, and an alkaloid have been reported for the genus (Schultes and Rafauf 1990). Furthermore, cyanogenesis has been found in one species. Myrcetin glucosides are known to be in *C. cainito*.

Certainly, the best-known species in the genus *Chrysophyllum*, and the one to which satinleaf is compared by most people, is *C. cainito*. That species apparently grows nowhere in the wild but is cultivated at least in Hispaniola and Cuba to Mexico, Central America, and northern South America. Some consider it to be native in the Caribbean and think that it subsequently was taken to the mainland in cultivation. From what is known, the uses of satinleaf and those of *C. cainito* are largely comparable.

As a comparison for common names *C. cainito* is called *abiu do Pará* (*abiu* or *Pouteria caimito* from Pará, Brazil), *caïmite* (Hispaniola, Trinidad), *caïmite des jardins* (garden caimito, Hispaniola), *caïmite franche* (free caimito, Hispaniola), *caimitero* (caimito tree, Puerto Rico), *caïmitier* (caimito tree, Hispaniola), *caimito* (Puerto Rico, Cuba, Colombia), *cainit* (English Antilles), *cainitier* (caimito tree, French Antilles), *cainito*, *cayumito* (Mexico), *goldenleaf*, *grande caïmite* (big caimito, Hispaniola), *kaimit* (Trinidad, Dutch Antilles), *kê-sê-weê-ree* (Yukuna, Arawakan), *so-da-deé* (Andoke, Witototan language group), *star apple* (Florida to Guyana), *star plum*, *sterappel* (star apple, Dutch Antilles), and *ta-uh* (Tikuna, Arawakan?).

The wood of this species is used in the same way that satinleaf is used. However, the fruit of *C. cainito* is large enough and sweet enough to provide a real treat. Many prize the fruits, while others dislike the gummy aftertaste. The fresh fruit is high in niacin (0.8 to 1.05 mg/100 g). Supposedly, the green fruit is astringent and becomes laxative when mature. Apparently, ample quantities must be eaten because a normal portion has no obvious impact on most people. To make the claim more confusing, it is also said that “overindulgence in fruit induces constipation and gastralgia” (Morton 1981). Leaves of this species too are used in medicine, and all parts of the tree are high in tannin. The latex has been used to adulterate rubber, and the Yakuna use latex for fungal infections of the crotch. The Tikunas use the latex on infected gums (Schultes and Raffauf 1990).

### *Chrysopsis*

(From Greek *chrysos*, gold, and *opsis*, aspect or resembling; from the golden inflorescences)

***Chrysopsis mariana*.** a. Flowering shoot. b. Basal rosette leaf, c. Dried head with only some florets shown, d. Mid series phyllary (involucral bract) with chlorophyllous zone dark. *Drawn by John C. Semple. Modified from Semple 1981.*

***Chrysopsis mariana*** (of Maryland) [Maryland] golden-[aster, star] (“golden,” in reference to color has been combined with various plants since at least the 1570s, and probably before; the OED 1971 lists 33 combinations; “aster” and “star” are not among them)

This genus was long part of the confusion involving what are now known as *Heterotheca* and *Pityopsis*. John Semple (1977, 1980, 1996, Semple et al. 1980) resolved those problems. More discussion is given under *Heterotheca*.

The Delaware used an infusion of roots to calm sick infants, and as a tonic for them (Moerman 1998).

### ***Cicuta***

(Latin for the poison hemlock, *C. virosa*; the Greek philosopher Socrates, charged by the government with impiety and corruption of youth, drank hemlock to commit suicide in the spring of 399 B.C.)

***Cicuta maculata*.** From Institute of Food and Agricultural Sciences.

*cicuta* (from Latin, Italian); *cicutaire* (French); *ciguë aquatique* (water cicuta, French)

cowbane

*fealladh-bog* (*fealladh*, false, *bog*, marsh, Gaelic) *selsnepe* (*selleri*, celery, *nepe*, turnip, Norwegian) *Wasserschierling* (*Wasser*, water, *Schierling*, hemlock, German)

***Cicuta maculata*** (spotted, noting colored spots particularly on stems) (= *C. curtissii*)

beaver poison (Texas)

*cafā:mcó:bī* (*cafā:m*=?, *có:bī*, big, Mikasuki); *ka: kīmba* (Creek)

*carrotte de Moreau* (Moreau's carrot, from a Frenchman who died from eating them; see Fernald et al. 1958)

[spotted] cowbane (USA)

*machiskatask* [*maciskatask*] (Cree); *manito-skatask* (*manito*, spirit, Plains Cree)

muskrat-weed (USA); musquat-root (variant of muskrat, USA)

[common, spotted] water hemlock (USA)

*yagodi* (Slave, Canada)

*zhon'-xa-shton-ga* (*zhon'-xa*, a counting stick, *shton*, habitually, *ga*, by blows, Osage)

That the Greek scholar Socrates (ca. 470–399 B.C.) used *Cicuta* to commit suicide indicates the antiquity of European familiarity with this genus, particularly *C. virosa*, the Old World species. However, there are seven other species in the genus, including the American plants. Mabberley (1997) thought that possibly *Cicuta* contains the most violent poisons of all northern temperate plants.

Although *Cicuta* contains the virulent poison cicutoxin, a resinoid that affects the nervous system, people have used it as a medicine. A single bite is said to be enough to kill a human (Diggs et al. 1999). Although it is a drastic poison, the Seminoles used it to treat fever (Sturtevant 1955). The Osage used the root to treat bruises and swellings and to reduce inflammation (La Flesche 1932). Farther north in Canada, the Ojibwa also used it and even “smoked the root” to attract deer (King 1984).

### ***Cirsium*: Thistles**

(From Greek *kirsion*, some kind of thistle)

We all know a thistle, even if we do not know much about plants. A thistle is a nasty prickly herb reaching head-high that sticks you when you pass. Essentially, the word “thistle” has been a generic name for spiny, armed plants since about A.D. 725. Not long after that date it was restricted to plants in the Asteraceae usually with lavender or purple flowers. We now put many of these in the genus *Cirsium*, and

***Cirsium horridulum*. Drawn by  
P.N.Honychurch.**

most of the others go in the related genera *Carduus*, *Cnicus*, and *Onopordum*.

As common as the plants are in temperate regions, there is a mystery about the origin of their English common name, thistle [*thistil*, *thistel*, *thystel*]. The best that can be said is

that it is Germanic. There are variants in German and Dutch (*distel*), Old Norse (*thistell* or *thistill*), Swedish (*distel*), and Danish (*tidse*). From about 725 until the 1500s, much of the literature equated the common name with *Carduus*. Then, with its creation in Philip Miller's *The Gardeners Dictionary* (4th edition, 1754), there was a shift to equating *Cirsium* with the common name "thistle." Since then, there has been a shuffling of species from *Cirsium* to *Carduus* with few agreeing exactly where one ends and the other begins. As it is now defined, *Cirsium* comprises about 250 species, with 50 in Europe and about 50 in temperate North America (Kartesz 1994, Mabberley 1997). Florida has seven species, only one of which is alien (Wunderlin 1998). At least six of the Florida species have been called *Carduus* at one time or another. Only *C. horridulum* and *C. nuttallii* are common species. Some consider Florida lucky to be free of the worst weedy species (Holm et al. 1991).

Plants called *Cirsium* have a venerable history. There was a kind of thistle called *kirasion* in Greek by Dioscorides (fl. A.D. 40–80), who used it to treat varicocele and other problems of the veins. Greek legend also records that Earth made the thistle in a moment of grief for the loss of Daphnis, shepherd and musician, poet and hunter. Although the Greek lamented the loss of Daphnis, the Norse esteemed the plants. Norse mythology records that Thor, the thunderer, protected the plant, along with all those who wore it. The Norse called them the "lightning plant" (Lym and Christianson 1996). Pliny (A.D. 23–79) Latinized the Greek name to *Cirsion*, and that use was continued by Miller in the 1750s with the spelling changed to *Cirsium*.

There is a strong association with Scotland and the thistle, including an image of one on its heraldic emblem. According to a notice published in 1488, that emblem is a "couering of...purpir tartar browdin with thissillis and a vnicorne" (covering of...purple tartan bordered with thistle and a unicorn).

According to legend, the Scottish people venerate the thistle because it saved them during a war. The event took place when Norsemen invaded Scotland during the reign of Malcolm I (A.D. 938–958). These Norsemen were trying to subdue Staines Castle. One night the invaders took off their footgear to wade through the moat surrounding the castle. Instead of finding water in the dark they found the moat dry and filled with cotton thistles (*Onopordon acanthium*). Their painful yells and curses aroused the garrison and the Norse were defeated. In memory of this victory the thistle became the floral emblem of Scotland, and the "cotton thistle" was renamed the "Scottish thistle." In 1540 King James V established the *Most Noble and Most Ancient Order of the Thistle*. King James VII revived it, knighting eight noblemen in 1687. In 1703 Queen Anne increased the number knighted to 12.

The thistles are such important plants in Scotland that there are two generic words for them in Gaelic. Some species are designated *fòthannan* (as in *fòthannan achaidh*, field thistle, *Cirsium arvense*; or *fòthannan Baltach*, Baltic thistle, *Carduus crispus*), and others are called *cluaran* (as in *cluaran deilgneach*, prickly thistle, *Cirsium vulgare*; or *cluaran Leana*, English thistle, *Cirsium palustre*).

People have uses for various species throughout the range of the genus *Cirsium*. By far, the most noted of the two common species in Florida is *C. horridulum* (the horrible thistle). That Latin name was given to these plants by Frenchman André Michaux in 1803 in his book *Flora Boreali-Americana* (Flora of North America). The continent seemed much smaller at that time because the Lewis and Clark expedition had not yet taken

place. That expedition's famous trip up the Missouri River system to the Pacific did not start until 1804. There is another connection between Michaux and that famous journey—that Frenchman almost became the botanist on the trip (Taylor and Norman 2002). If President Jefferson had not been fighting with the French over Louisiana and with the Spanish over the lands near California, it might have become the “Michaux Expedition.”

For some odd reason, the “accepted” common name of *C. horridulum* is yellow thistle in the United States. Since the flowers are purple in Florida (at least in the southern part), that name seems wrong. Reports say that flowers may be yellow elsewhere. Other people may call *C. horridulum* the bull thistle (Texas to the Bahamas), or simply say it is a thistle. This plant is almost confined to the southeastern United States coastal plain, from Texas to Florida to Maine and the Bahamas. There is also a record of it in Chiapas, and Correll and Correll (1982) indicate it has been found elsewhere in Mexico.

The Miccosukee know the plants as *tokifäski* (sharp thistle), their relatives the Creeks say *aká:co* [*aga'djo*], and in Muskogee the plants are called *vkaco* [*vkácv*, *vkacv*, *kotacv*]. Their relatives, the Chickasaws, call their plants *oktaak pilhchi*’ (*oktaak*, prairie, *pilhchi*, thistle). Choctaw say *shumatti* (blowgun dart) or *shumo* (down), which is the same meaning as Koasati *fohpô*.

The only use attributed to these plants by the Seminoles who talked with Sturtevant in the 1950s was to make blowgun darts. Presumably, they used the pappus from the fruit clusters as “feathering” on the base of their darts so that they would catch air in the gun. People in South America use a similar material from kapok trees (*Ceiba pentandra*) for their darts. Relatives of the Seminoles, the Houma of Louisiana, have more uses for thistle, which they call *chardron*, a local form of the French word (Speck 1941). They use an infusion of leaves and roots in whiskey and find it a strong astringent. Further, an infusion of leaf and root will clear phlegm from the lungs and throat. The tender white hearts are eaten raw. Probably, the Seminoles knew of those uses in the past. Even by the 1950s many were forgetting old herbal uses or dying without training apprentices. Alice Snow no longer uses *Cirsium* (Snow and Stans 2001), and Bennett (1997) did not find it in use. Other people also found that an infusion of *C. horridulum* could be used against colds, dyspepsia, and diarrhea (Hocking 1997).

People in the Bahamas also use the plants. As with the Houma, they eat the succulent stems. To do that they chop them up and eat them fresh, or they put them in salads. Sometimes they pickle them in vinegar (Correll and Correll 1982).

Raw thistle achenes are bitter but may be roasted and eaten. The young leaves of several species with the spines removed can be served as a salad or cooked like spinach (Fernald et al. 1958). The inner stem pith can be steamed and served like asparagus. The heads can be used as rennet to curdle milk for cheese making (Lym and Christianson 1996).

Both the Spanish and French depart in their common names from the *Cirsium* root words and call these armed herbs *car do* (Spanish), *cardillo* (New Mexico), and *chardón* (French). Those words are based on Latin *Carduus*. This was the name used by classical authors Virgil (70–19 B.C.) and Pliny (A.D. 23–79), and by Linnaeus ([1753] 1957) for a variety of bristly plants related to *Cirsium*.

There are reports of several groups using *C. mexicanum*. The Zapotec call it *guia dona* [*guie tana*] (*guia*, flower, *tana*, dry), and the Maya say *omil*. Other people in Mexico say

it is the *cardo santo* (holy thistle) or *cardo santo macho* (male holy thistle), and use it to treat colds as with other species. In the French Antilles the species is known as *chardón* (Guadeloupe, Martinique) or *chardón-amourette* (bitter thistle, Guadeloupe, Martinique). Other species are called *cardo* in Mexico and Central America, and sometimes called *cardón*. The cacti *Cereus aragoni* (Costa Rica) and *Pachycereus pringlei* (Baja California, Sonora) are both called *cardón*. Calling a cactus *cardón* never made any sense to me until I realized it was a comparison to other spiny plants in the same sense as using the word *cactus*. Both *cardón* and *cactus* are generic terms for prickly plants.

From the way people treat the names “thistle” and *cardo*, they seem to regard the species in *Cirsium* as being all the same. There are records of at least 29 species from Europe and the Americas being used. Most of the literature on the genus consists of attempts to control some weedy species, but a few discuss medically active compounds. Within the genus, people have identified acetates, alkynes, flavonoids, glucosides, flavone glycosides, and volatile compounds (Takano and Kawaminami 1988, Takaishi et al. 1990, Binder and French 1994, Martínez-Vazquez et al. 1998). These substances have been reported in Japanese, Mexican, and European species. The chemicals have been shown to reduce pain and inflammation, and control blood sugar, at least in the laboratory (Martínez-Vazquez et al. 1998, Iwashina et al. 1999, Pérez et al. 2001). As those are maladies the plants are used to treat, there is support for their medical effectiveness.

Several groups and uses are reported with only the generic name, which may represent several species. Even if that is correct, the uses reflect what was probably done historically in Florida. The Huastec call thistles *cholich* [*tzolich*] (San Luis Potosí, Mexico), and they are used against dysentery, aches and pains, and coughs. These same people consider them a *milpa* (corn field) weed that is also a forage readily eaten by horses (Alcorn 1984). Within the United States and Canada, some species of *Cirsium* has been used, in addition to those named above, by the Abenaki, Apache, Atsugewi, Blackfoot, Cahuilla, Cherokee, Cheyenne, Chiricahua and Mescalero, Comanche, Costanoan, Cowichan, Cree, Delaware, Flathead, Gosiute, Hopi, Iroquois, Kawaiisu, Kiowa, Kwakiutl, Meskwaki, Montagnais, Navajo, Nitinaht, Ojibwa, Okanagon, Paiute, Potawatomi, Quileute, Ramah and Kayenta, Spokane, Sushwap, Thompson, Tubatulabal, and Western Keres (Smith 1933, Moerman 1998). That pretty well covers all four corners of North America and Mexico.

### *Cissampelos*

(From Greek *kissos*, ivy, and *ampelos*, a vine; referring to foliage and similarity to *Cissus*)

***Cissampelos pareira*.** a. Lower part of the stem. b. Part of the pistillate inflorescence, c. Segment of staminate inflorescence with open flower, d. Staminate flower longitudinally dissected, e. Floral diagram of staminate flower, f. Pistillate flower, g. Pistillate flower longitudinally dissected, h. Floral diagram of pistillate flower, i. Fruit. Drawn by Priscilla Fawcett. Correll and Correll 1982.

***Cissampelos pareira*** (from Portuguese *parreira*, vine, alluding to a resemblance to the grape vine, *Vitis*)

*abútua* (twining plant in the family Menispermaceae, Tupí, Brazil)

*alcoán [de la tierra] [cotán]* (*alcoán* is usually a name given to a type of hawk; thus, *alcoán de la tierra* would be “hawk of the earth,” Nicaragua, Guatemala, El Salvador)

*aristoloche lobée* (lobed *Aristolochia*, Haiti)

*barbasco* (Peru)

*bejuco azul* (blue vine, Costa Rica); *bejuco de alcoán* (hawk vine, El Salvador); *bejuco de mono* (monkey vine, Puerto Rico); *bejuco de pitilla* (little flower vine, Cuba); *bejuco de preñada* (pregnant woman’s vine, Guatemala); *bejuco de ratón* (mouse vine, Dominican Republic); *bejuco*

- de sabana* (savanna vine, Cuba); *bejuco de terciopelo* ([snake] *Bothrops* vine, Cuba); *bejuco name* (yam vine, Dominican Republic)  
*butua* (Colima, Guerrero, Veracruz)  
*caapeba* (*caa*, plant, *peba* from *pewa*, large boat, Tupí, Brazil)  
*cipó de cobras* (goat vine, Brazil); *cipó de cobra* (snake vine, Brazil);  
*cipó de gota* (drop vine, Brazil)  
*curarina [de monte]* ([wild] little healer, Chiapas, Guatemala)  
*cuxbá [cuxogui]* (Quecchí, Guatemala)  
*erva de nossa senhora* (Mary's [our Lady's] herb, Brazil)  
*estrella de la preñada* (pregnant woman's star, Guatemala)  
false *pareira* root (a root confused with the "real *pareira*," *Chondodendron tomentosum*)  
*feuille coeur* (heart leaf, Haiti)  
*guaco [huaco]* (Veracruz, Guatemala; for more on *guaco*, see *Manfreda*)  
*hierba de la vibora* (snake herb, San Luis Potosí)  
*hierba ratón* (mouse herb, Venezuela)  
ice vine  
*imchich masha* (Quechua, Peru)  
*ischochichac* (Totonac, Veracruz); *ixcatú-can* (*kan*, yellow, Maya, Guatemala); *k'on k'ach* (Huastec, San Luis Potosí)  
*iztac-coanenepilli [istaconenepilli]* (*iztac*, white, *coatl*, serpent, *nenepilli*, tongue, an herb used as an antidote, Náhuatl, Mexico)  
*liane [a] serpent* (snake vine, Haiti, Guadeloupe, Martinique); *liane à coeur* (heart vine, Haiti, Guadeloupe, Martinique); *liane amère* (bitter vine, Guadeloupe, Martinique); *liane corde* (cord vine, Guadeloupe, Martinique); *liane gourde* (gourd vine; probably a corruption of *liane corde*, Haiti); *liane molle* (soft vine, Guadeloupe, Martinique); *liane patte cheval* (horse hoof vine, Haiti); *liane quinze jours* (15 day vine, Guadeloupe, Martinique)  
*oreja de ratón* (mouse's ear, Guerrero, Michoacán, Guatemala, Puerto Rico)  
*orelha de onça* (jaguar's ear, Brazil)  
*palikur* (probably from *palikar*; derived from Greek *palikaris*, valiant, Peru)  
*pareira* (used in English by 1715, from Portuguese *parreira*, vine); *pareira brava* (wild vine, Oaxaca, Veracruz, Jamaica, Barbados); *parreira brava* (wild vine, Brazil); *parreira do mato* (wild [forest] vine, Brazil)  
*pataka* [*pathaca*] (variant of *patate*, potato, Virgin Islands); *patacón* (big potato, Trinidad)  
*patte cheval [pat chawal]* (horse hoof, Haiti)  
*pegamo* (Colima)  
*peteltún* (Maya, Yucatán)  
*picamano* (hand stinger, Nicaragua)  
*quacori* (Cayman Islands)

*tamagás* [*tamasás*] (the poisonous viper *Bothrops*, Guatemala, Nicaragua)

*tomatillo de sabana* (savanna tomato, Cuba)

*tortilla de los sapos* (toad's tortilla, Veracruz)

*ts'its'uk-ak'* [*tsutsuc*] (*ak*, vine, Maya, Yucatán)

*uxum ichich* (woman medicine, Huastec, San Luis Potosí)

velvet-leaf (Jamaica, Virgin Islands, Barbados)

*venadera* (poisonous one, Costa Rica)

*walik ts'ohool* (evil eye plant, Huastec, San Luis Potosí)

*Cissampelos pareira* is one of those nondescript climbers that people rarely look at closely, even if they are supposed to be critical. This climber occurs in the American tropics, through the Old World tropics, and in Australia (Mabberley 1997). The vine has 101 scientific names that have been applied to it (synonyms) because of its variability and the fact that people did not examine it closely.

*Pareira brava* became known in Florida when it was collected in 1929 by E.C.Marquard in what is now Matheson Hammock Park, and then listed in the *Manual of the Southeastern Flora* (Small 1933). In Florida, the plants were confined to a small area in Miami-Dade County. Indeed, the plants have always been so rare in southern Florida that they almost did not exist. There are no specimens in the database maintained by Fairchild Tropical Garden, and I never saw the species in 31 years of fieldwork there. The Florida Department of Agriculture considered the vines endangered in the state (Coile 2000) and wondered if they had been extirpated. So far as known, the last plants were accidentally killed around 1993 at Matheson Hammock State Park when a restoration crew mistook the plant for an exotic that was meant to be destroyed (Gann et al. 2002).

The species is so widely and commonly used by people that it might even qualify as a floristic element introduced by humans. However, the bright red, fleshy fruits are relished by birds, so the human-introduced conclusion is at least uncertain.

The first European reference to these plants was made in 1648 by German pioneer in tropical medicine Georg Marggraf, who found it being used in eastern Brazil. He called them *Caapeba brasiliensibus*. From that point until Linnaeus studied them for his *Materia Medica* of 1749, confusion about their identity reigned. John Ray in 1686–1688 considered them a *Convolvulus*. Hans Sloane in 1696 thought the vines should be a *Clematis*. Leonard Plukenet in 1700 thought they were a *Hedera*. Charles Plumier thought he found another species in the Caribbean but continued calling them *Caapeba* in 1703.

In 1715, the British journal *Philosophical Transactions* of London published an article that included the following: “The *Pareira Brava* is a Root which comes to us from Brazil by way of Lisbon.” The OED (1971) says that “pareira” is a “drug made of the root of a Brazilian shrub, used in disorders of the urinary passages. Originally understood to be the root of *Cissampelos pareira* or ‘Velvet leaf,’ the *pareira brava* of the Portuguese, whence the name: now said to be that of a different shrub, *Chondodendron tomentosum*; the ‘Velvet leaf’ being distinguished by some as the *Spurious pareira*.” The same source confirmed that the “real pareira” is *Chondodendron tomentosum*; so, *Cissampelos*

*pareira* is relegated to being the false *pareira*. Both twiners are in the same family, the Menispermaceae, and they have been used for the same purposes.

People throughout the range of *pareira brava* have uses for the plants. It was those uses in Brazil that captured Georg Marggraf's (1610–1644) attention when he and Dutch physician Willem Piso (ca. 1611–1678) went there in 1637. In Mexico, where the Aztecs knew the plants under the name *itztaccoanepilli*, one of the important uses was to treat bites of poisonous animals, particularly snakes (Martínez 1969, Vásquez and Jácome 1997). Standley and Steyermark (1946) wrote: "Throughout much of tropical America they have a high reputation as a remedy for bites of snakes and other poisonous animals." Uphof (1968) also noted that the vines were used by Chinantecs and others for snakebites. Others noting that use include Liogier (1974), Duke and Vásquez (1994), and Hocking (1997). The snake-bite aspect was even noted by Rudyard Kipling's 'Kim' (Hocking 1997).

The species was treated among indigenous remedies in the journal *Economic Botany* in nine articles between 1947 and 1996 (Jain 1965, Duke 1970, Jain and Tarfder 1970, Lipp 1971, Wong 1976, Arenas and Moreno 1977, Bedi 1978, Manandhar 1991, Coe and Anderson 1996). Five of those were American uses, and the others were from India and Nepal. Medical use is also listed by Roig (1945), Uphof (1968), Liogier (1974), Morton (1981), von Reis and Lipp (1982), Duke and Vásquez (1994), Hocking (1997), Mors et al. (2000), and numerous other American publications. Duke et al. (2002) summarized the uses, listing its activities as alexeteric, analgesic, antiabortive, anti-inflammatory, antipyretic, astringent, bitter, curare, depurative, diaphoretic, diuretic, emmenagogue, expectorant, hemostat, litholytic, myorelaxant, piscicide, poison, sedative, stomachic, tonic, and vulnerary. They continue with uses that include treatment for acne, amenorrhea, asthma, bleeding, calculus, catarrh, childbirth, cough, cystosis, dermatosis, diarrhea, dropsy, dysentery, dyspepsia, dysuria, enterosis, fever, gastrosis, gravel, hemicrania, hemorrhoids, inflammation, insomnia, jaundice, nephrosis, nervousness, pain, prolapse, rash, sinus infection, snakebite, sore, sting, stomachache, stone, tuberculosis, ulcer, urethrosis, urogenitosis, uterosis, venereal disease, water retention, worms, and wounds. It would seem to be a panacea, but they give it a single "plus," which means they think it is not as safe as drinking a cup of coffee (and Jim Duke noted that he often drinks more than three cups of coffee a day).

Surely because of the worldwide use by indigenous people, and because the vines belong to the same family as some of the most famous sources of curare, they have been subjected to more chemical analysis than many others. Uphof (1968), Wong (1976), Morton (1981), Duke and Vásquez (1994), and Mors et al. (2000) note that the roots contains alkaloids including bebeerine (pelosine), cissamine, cissamparine, dehydrodicentrine, curine, cyclenine, dicentrine, hyatidine, hyatine, hyatinine, insularine, isochondodendrine, menismine, pareirine, and tetrandine. Of these, cissamparine has shown antitumor activity (Morton 1981), tetrandine is analgesic, anti-inflammatory, and febrifuge (Duke and Vásquez 1994), and chemicals of the bisbenzylisoquinoline type exhibit high cytotoxic activity (Mors et al. 2000). Hyatine has muscle relaxant and hypotensive effects (Wong 1976).

***Cissus*: Possum Grape**

(From the Greek *kissos*, ivy, referring to the climbing habit)

Although the plants had been known in Florida for many decades before David Fairchild introduced new genetic strains into the state, he worried about

***Cissus verticillata*.** a. Branch, b. Flower, side view. c. Flower longitudinally dissected, d. Floral diagram, e. Fruits. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982.

them. Fairchild quipped that those he introduced might lead to him being remembered as a “Damnable introducer of weeds” (Fairchild 1947). Anyone who has tried to pass through a tangle of these plants would understand his comment.

In Florida the species is called possum grape, and for many years it was *Cissus sicyoides*, a name Linnaeus gave it in 1759. However, in one of his uncommon lapses, Linnaeus had actually given these plants a name in 1753. The earlier name is the one that must be used. It appears that Linnaeus was misled by the citation from Hans Sloane published in 1696. In his treatise on Jamaican plants, Sloane had written that one was a *Viscum ramulis & folis longis dentissimis straitis & radiatis* (mistletoe with branches and long leaves toothed, ridged and rounded), and that it was a parasite. So, Linnaeus called Sloane’s plant *Viscum verticillatum*. When he encountered the same species in 1759, he did not recognize it and called it *Cissus sicyoides*. This vine was known as *C. sicyoides* until Dan Nicolson (Smithsonian Institution) and C.E. Jarvis (Natural History Museum, London) discovered the mistake and corrected it in 1984. This pair gave us the correct modern name of *C. verticillata*.

Although Sloane's was the first record of these American plants known to Linnaeus and most other Europeans, his was not the first report of them. Earlier, Francisco Hernández (1651) listed the climbers and recorded that the Aztecs of Mexico called it *tlacamatzcazqui y papan* (*tlacatl*, human, *maçatlozqui*, medicinal plant, *papan*, upon, apparently meaning "medicinal plant for use on humans"). More recently, it has been recorded in Náhuatl as *molonqui* (sprawler, Valley of Mexico), and *tepemecatli* (*tepetl*, in the mountains, *mecatli*, rope, so it is wild rope). It was supposedly also listed by Hernández as *temecatli* and considered a laxative herb. Its Spanish name *tumbavaqueros* (cowboy tumbler, Valley of Mexico, Morelos, Hidalgo) has the same connotation. *Tumba-vaqueros* is also applied to many species of Convolvulaceae that are notably laxative. That interpretation is further supported by the name bastard bryony (Jamaica, Trinidad). Bryony is *Bryonia*, a member of the Cucurbitaceae, and a notorious purgative.

All the Náhuatl ideas are recorded in other modern names. The fact that it "sprawls" over everything nearby is consistent with Fairchild's worries. Some of the names that convey the notion of scrambling plants covering everything are *achite* (synonym for *anil-trepador*, Brazil), *anil trepador* (blue climber, Brazil), *bejuco caro* (expensive vine, Puerto Rico, Hispaniola), *bejuco Castro* (Castro's vine, Colombia), *bejuco chirriador* or simply *chirriador* (*chirriar* is slang for going on a spree, plus vine, Colombia), *bejuco comemano* (hand-eating vine, Guatemala, Honduras, Central America), *bejuco de caro* (expensive vine, Puerto Rico, Dominican Republic, Venezuela), *bejuco loco* (crazy vine, Tabasco, Panama), *bejuco loco rojo* (red crazy vine, Tabasco), *caro* (expensive, Cuba), and *picamano* (hand biter).

Surely, a derogatory connotation is also implied by several other names. These include *bejuco de gallina* (chicken vine), *tripa de Judas* (Judas's guts, Valley of Mexico, Morelos, Hidalgo, Oaxaca), *tripa de vaca* (cow guts, Guanajuato), and *tripa de zopilote* (vulture guts, Sinaloa).

Names showing that the plants were used to create strings or rope are similarly varied. In Florida, the Creek-speaking Seminoles called it *chu:los:sho:a:kee* (*culoswuce*, possum grape =?) or *baksló:cí* (black strings). Their relatives the Mikasuki speakers have the same name in *baksó:cí* (black strings). Another Seminole name is *afoslasti*, based on Muskogee *vfuswv*, strings, and *lvste*, black. Both use the vines to make strings and ropes, and medicinally (Sturtevant 1955). Historically, Seminoles used the fibers from the stems to make bowstrings.

The Maya of Yucatan also use the stems for ropes. They say it is *tab-kanil* (*tab*, string, *kanil*, secondary root). In other words, it is a plant used to make cords that are used to carry things on the shoulders. The Maya also call it *tab-kaan* [*ta-kan*] (*tab*, cord, *kaan*, yellow, Yucatan, Belize) or *ya'ax-tabkanil* (yellow string rope). In Panama it is rock rope. Although the names do not say so directly, the stems are also used in making baskets (Mexico, Jamaica). Maybe *cortina de pobre* (curtain of the poor, Brazil) indicates fabrication of curtains from the stems.

Many of the names indicate medicinal uses. In Peru, two names associate it with souls or spirits. These are *ampato huasca* (defending spirit, Quechua) and *zapo-huasca* (toad's spirit, Quechua). In Brazil, the plants also are called by two different names. They are either *pucá* or *cipó-pucá* [*cipó-puci*] (*pucá* vine, from Tupí *pi'sá*, fruit of *Rauvolfia bahiensis*) to compare them with another medicinal plant. Alternatively, they may be called *caavurana de cunha* (*caá*, herb, *caavurana* is medicinal *Solanum caavurana*,

*cunha*, woman, Tupi). The most common usage of *Cissus* is for skin diseases, and this Tupi name compares it with one of the plants that they use to treat leprosy. Perhaps *caavurana* is a man's medicine, and *caavurana de cunha* is for women.

Other names that suggest remedies for skin problems include blisterbush (Jamaica, Trinidad), *cuacua* (a Creole word, Nicaragua), *herbe à ulcères* (herb for ulcers, Hispaniola), *pico de mono* (hand sticker, Nicaragua), scratch wys (scratch vine, Jamaica, Trinidad), and yaws bush (Jamaica, Trinidad). Some specific examples of uses include crushed leaves with an oily carrier used to treat itchy skin in Curaçao (Morton 1981). In Mexico, the bark is crushed in alcohol and used to treat skin problems (Martínez 1969). In Jamaica the stems are mixed with fat or castor oil and used on boils and bruises. In a number of places the leaves are used as poultices on tumors, boils, hemorrhoids, abscesses, and sores. The sap is also used on sunburn. In Guatemala the sap is used to treat gangrene.

Surely, the most inclusive common name is *sánalo todo* (cure-all, Veracruz). Sometimes the vines are compared to others, such as wild yam (yam is *Dioscorea*, in Jamaica, Trinidad) or *yedra* (ivy). Perhaps those associating the plant with snakes are alluding to its medicinal properties. Those names include *paja de la culebra* (snake straw), snake bush (Jamaica, Trinidad), and snake wys/withe (snake vine, Jamaica). Perhaps poison wyth (English Antilles) has the same meaning. Mary bush (Jamaica, Trinidad) carries an unspecified application. Probably the names *iasu* or *bejuco iasu* (*iasu* vine, Costa Rica) and *liane a minguet* (*minguet* vine, Hispaniola) indicate uses that are obscure.

Additionally, the leaf decoction taken internally or in baths is used to treat rheumatism in Mexico, Cuba, and Hispaniola (Roig 1945, Martínez 1969, Liogier 1974). Gargles of the decoction of the leaves are used against throat infections and flu (Hispaniola). In Brazil, tea from leaves is drunk as a treatment for heart problems, tachycardia, hydropsy, high blood pressure, and anemia (Mors et al. 2000).

As with the common name possum grape, many others make comparisons with other Vitaceae. The vines are called *bejuco de parra* (grape vine, Hispaniola), *bejuco ubí* (grape vine, Cuba), *parra de monte* (wild grape, Mexico), pudding bush (Jamaica, Trinidad), pudding vine (English Antilles), pudding wys/ withé (Jamaica), *ubí* (grape, Cuba), *uva* (grape, Oaxaca), *uva brava* (wild grape, Panama, Brazil), *uva cimarrona* (wild grape), *uva silvestre* (wild grape, Mexico), *uvilla* (little grape, Nicaragua), *uvilla silvestre* (little wild grape), and *vid silvestre* (wild vine, Hidalgo, Veracruz). Fruits are consumed by many animals; however, that should not be taken to imply that the fruits are edible for humans.

Although the sap contains enough saponin to make it lather like soap and be used like soap, it is also consumed. The names *bejuco de agua* (water vine, Colombia), *yucohuira* (water vine, Mayo, Sonora), and *liane a eau* (water vine, French Antilles) suggest that it may be used as a source of water. It is said to have a slightly acidic flavor, and it is used simply as a water source in Colombia and Sonora (Pérez-Arbelaez 1978, Yetman and Van Devender 2001). However, most people use the "water" medicinally. In Hispaniola a tea from the plant is used for colon inflammation to reduce fever, and it becomes diuretic when mixed with cactus fruits, maize silk, and sugar cane (Liogier 1974). In Amazonian Brazil, the sap is used against epilepsy, and preliminary data suggest possible anticonvulsive traits (Mors et al. 2001). Moreover, in addition to saponins, the species

contains anthocyanins (Toledo et al. 1983). Presumably, it also contains stilbenes, flavonols, quercetin, kaempferol, resveratrol, piceatannol, pallidol, and parthenocissine a, like its relative *C. quadrangularis* (Adesanya et al. 1999).

In Brazil, *C. verticillata* is called *tinta dos gentios* (gentile's dye). There and elsewhere it provides dyes (Morton 1981, Mors et al. 2000). In Colombia, Mexico, and Jamaica, the fruits are used to prepare a blue dye.

There are several names with obscure allusions. These include *boeng able ma* [*boen atti mama*] (tree heart mother, Sranan, Suriname), *cabuja di tranke* [*kaboeja di tranker a*] (*kaba*, end, *di*, for, *tranga*, strong, Sranan, Dutch Antilles, Suriname), *fei mush* [*feuille mouche*] (fly leaf, Jamaica, Trinidad), *feuille cotaire* (numbered leaves, Hispaniola), godmort (St. Lucia), lambrall (English Antilles), *omhein-ingtouw*, *paramaru* (Carib, Suriname), and pinakoop (English Antilles). *Prenada segunda* (Belize) seems to mean a "second light"; perhaps the stems were used for candles.

My favorite name is *coronilla* (Belize), the little crown. Although trying to get through a tangle of these climbers will elicit four-letter Anglo-Saxon words, they do crown their host admirably.

### *Citharexylum*: Fiddlewood

(From Greek *kithara*, an ancient lyre-like instrument, and *xylon*, wood)

*Citharexylum fruticosum*. a. Branch with flowers, on left, old male spike with most flowers fallen, b. Node, with axillary bud enclosed by leaf base. c. Flower, side view. d. Flower, from above, e. Staminate flower

longitudinally dissected. f. Staminode and two stamens in staminate flower. g. Pistillate flower longitudinally dissected, h and i. Floral diagram of staminate and pistillate flowers, respectively. j. Fruiting branch, st.=staminode. *Drawn by Priscilla Fawcett*. From Correll and Correll 1982.

There are two stories about how fiddlewood (*Citharexylum fruticosum*, Florida to Panama and Trinidad) got its name. One is that wood from it was used to make fiddles (violins for those of highbrow tastes). The other is that the tree was known as *bois fidèle* (faithful wood) to the French, and that the English misunderstood and mispronounced the name. Take your pick.

Either way, the wood is involved, and its use in musical instruments is recorded in the name *palo de guitarra* (guitar tree, Puerto Rico). We are left to presume that Linnaeus learned of this usage in making musical instruments and selected the generic name to commemorate that fact. Linnaeus based the generic name *Citharexylum* on Greek *kithara*, an ancient lyre like instrument with a triangular body and 7 to 11 strings. Indeed, wood from the trees has been used to make fiddles, violins, guitars, and other musical instruments (Little and Wadsworth 1964).

To us in the 21st century, it seems curious that Linnaeus would choose the Greek musical instrument *kithara* in naming this genus. However, he tried to create generic names based on classical language words, and that was the one available to him. Modern words such as “fiddle” or “violin” did not exist in classical times, but were derived later, some from Latin-based Romance languages. The original versions of violin were *violina* (Italian and Portuguese) and *violin* (Spanish), supposedly diminutive forms of *viola*. It was not until the 1570s that the word “violin” appeared in English.

The word “fiddle” has an even more obscure origin. No one is sure, but it has been speculated that “fiddle” was adopted into Teutonic languages from Medieval Latin *vidula*. That Latin word may have given rise to *virole* (French), and ultimately to *viola* (Italian, Spanish, Portuguese). Yet, the words *viol* or *viola* did not appear in Romance languages until the 15th century, and the word “fiddle” appeared in English much earlier than did “viola” or “violin.” Fiddle was recorded in English by about A.D. 1205. Since the Germanic usage of these words predates those in the Romance languages, a Teutonic origin and subsequent adoption into Latin-based languages seems equally or perhaps more plausible.

Some books record our plants (*C. fruticosum*) as Florida fiddlewood, but people in the field will not know what you mean by that name. That is probably a name applied in the lumber trade. Supposedly, there is reason to call it white fiddlewood in the Caribbean and Central America where there is also a yellow fiddlewood (*C. caudatum*). However, *C. fruticosum* is called yellow fiddlewood in Jamaica.

Several other names refer to the quality of the wood. It is so hard that it is called *bois de fer blanc* (white ironwood, Guadeloupe, Martinique). In the same region, it is called

*bois carré* (turtle wood), presumably because of its dense wood, and perhaps because it grows near the coast.

Perhaps because they have a different taxonomic scheme from ours, some people compare fiddlewood to coffee. They know the difference, but still see a similarity. These people call it *café cimarrón [marron]* (wild coffee, Dominican Republic), or wild coffee (Bahamas). Others think it looks more like pomegranate (*Punica granatum*) and say it is *grenade* (pomegranate, Haiti) or *grenade marron* (wild pomegranate, Haiti). Yet others say it is like cinnamon (*Canella winterana*) and call it *canilla de venado* (deer's cinnamon, Cuba). In Panama, it looks to some like a *manglillo* (little mangrove). Cubans use an old Taino word and call it *guayo blanco* (white *guayo*).

Some think the drooping fruit clusters resemble necklaces and say it is a *collarete* (little necklace, Cuba). People in the Greater Antilles sometimes are more direct and simply say the flower and fruit clusters hang down with *penda* (dangling, Cuba, Dominican Republic), *péndula* (drooping, Puerto Rico, Dominican Republic), and *pindoula* (drooping, Haiti). Bahamians simply think it is a dirty tree and call it trash-a-berry.

However, many have discovered medicinal properties in the plants and given them names that reflect those properties. Balsams are universally recognized as medicinal, and *Citharexylum* is *bálsamo* (balsam) in Puerto Rico. The reference is obscure, but medical usage is indicated by the names long Tom (Bahamas) and *madame Claude* (Haiti). The most widespread name after fiddlewood is old woman's bitters (Puerto Rico, Virgin Islands, Panama), a clear indication of herbal usage.

The strangest name found, *susanaleche* (Virgin Islands), may also reflect medicinal use. The name may be derived from St. Susana who was beheaded in Rome in A.D. 295. The Catholic festival celebrating that event is held on 11 August. So, in keeping with their earthy and (to outsiders) often obtuse humor, the people in the islands refer to the tree as giving milk from Susan, the virgin saint.

*Citharexylum fruticosum* grows from the southern part of Florida, in the Bahamas, the West Indies from Cuba to St. Vincent, Grenada, and Trinidad, and from Venezuela to Suriname. Much of that range it shares with several of the  $\pm 70$  species in the genus (Mabberley 1997). Other species grow as far south as Argentina. One of the species with which it shares its range was also named by Linnaeus. Indeed, it was the first species he named in the genus, *C. spinosum*. Both kinds have been recognized as distinct by all who studied them until recently when a revision was published that considered them the same. If indeed they are the same, the Florida plants will have to be called *C. spinosum*, as Wunderlin (1998) did. However, pending more information, the old familiar name is continued here.

Various parts of fiddlewood have been used by people throughout its range. Probably the most commonly used part is the wood. Not only is the wood used for fuel and fence posts, but it is also prized for cabinetwork and musical instruments in several places (Little and Wadsworth 1964). There is disagreement about the color of the wood, since Little and Wadsworth (1964) say "reddish," Morton (1981) describes it as "red," and Liogier (1974) calls it "ash-colored." As they do not specify, they could be talking about different parts, the heart and sapwoods, which are usually different colored. Because I have not seen the mature wood, I cannot determine which may be which. Both Morton and Liogier agree that the wood is hard, heavy, and compact.

Fruits are somewhat like cherries, and they may be eaten. Most agree that only children like them, and Morton (1968b) says that the “ripe fruit is edible but not good.” Like many things, it probably depends on how hungry you may be.

As the common name “old woman’s bitters” suggests, there are several medical applications of fiddlewood. When a plant has a bitter taste, it is almost certain that it has been used in medicines; likewise, when it is aromatic. In both cases, people have experimented and used them to treat some malady.

The whole view that bitter is medicinal was enforced when quinine bark (*Cinchona* spp.) was introduced as a cure for malaria in the late 1600s. Because the remedy came from the Catholics, and was called Jesuit’s powder and then Jesuit’s bark, it was shunned by the Protestant world until 1820. Once established in the Catholic and Protestant realms, bitters became even more popular.

In the Bahamas, and judging from the common names many other places, the plants are medicine (Morton 1981). In the Turks and Caicos, the leafy twigs are boiled and the decoction taken to banish pain from exposure to chilly wind. When that same decoction is mixed with strongback (*Bourreria succulenta*) and spoonbush (*Thouinia discolor*), the decoction is administered internally and externally as a remedy for “bright” (running sores on a child’s body).

Fiddlewood boiled with mahogany (*Swietenia mahagoni*), lignum vitae (*Guajacum sanctum*), roots of doctor’s club (*Zanthoxylum coriaceum*), and snowberry (*Chiococca alba*), with latex of papaya (*Carica papaya*) added, makes a tea to dispel indigestion.

Fiddlewood is probably cultivated more than anything else for the fragrant white flower. Those small flowers perfume the air, especially at night, and attract a wide variety of insects. During the daytime they are visited by bees, wasps, and butterflies, and at night by moths. The plant is a virtual grocery store for insects, and those who grow it find both the insects and fragrance an addition to an already attractive tree.

### *Cladium*

(Greek *kladion*, a branchlet; named by Patrick Browne in 1766, possibly referring to the inflorescence)

*Cladium jamaicense* (from Jamaica)

***Cladium jamaicense*.** From Institute of Food and Agricultural Sciences.

- caña amarga* (bitter cane, Dominican Republic)
- cortadera* (the cutting one, Dominican Republic); *cortadera de ciéniga* (marsh cutting one, Puerto Rico); *cortadera dos filo* (cutting leaves, Brazil)
- cumaní* (Taino?, Dominican Republic)
- cutting grass (Belize)
- herbe [z'herbe] rasoir* (razor herb, Haiti)
- holche [holsache]* (*hol*, hollow, *che'*, herb, Maya, Chiapas; unlike most sedges, the stems [culms] are hollow)
- pahikóslî* (cutting grass, Mikasuki); *pahikosnâ* (*pvhe*, grass, *kaske*, scrape, Creek)
- paint brush grass (Belize)
- prickly sedge
- saibal* (Lacandon, Chiapas)
- [Jamaica, swamp] saw-grass [sawgrass] (a comment on the cutting leaf margins; in use by 1822, Florida to Panama)
- serrucho* (little saw, Puerto Rico, Panama)
- siba* (Yucatán)
- sticky grass (Bahamas)

When Patrick Browne (1720–1790) named this species from Jamaica in 1766, he created a genus that now has three species. Two are found in North America, and the other, *Cladium mariscus*, is almost cosmopolitan. The Old World species was known as “elk sedge” in Anglo-Saxon and was formerly used in thatching houses in Great Britain (Mabberley 1997).

The growing heart (apical meristem) is edible (Morton 1968b). It is a bit tricky to extract the heart without being cut by the leaves, but it provides a moist bite when successful. There is a slight resemblance to palm heart, but sawgrass hearts are not usually as sweet. Sturtevant (1955) found the Seminoles using the hollow stems as a *'sakpofketv* (medicine blowing tube). This refers to the Creek tradition of “blessing” medicinal plants. Part of that ritual included the *heles hayv* (traditional doctor) bubbling his breath through the liquid using a tube (Howard 1984).

Juice of the grated fruit is used to treat high blood pressure, and a plant decoction soothes chicken-pox eruptions in the Bahamas (Ayensu 1981, Morton 1981). Leaves have been used to make baskets and cheap paper (Eldridge 1975, Morton 1981). Balick et al. (2000) simply record that the sedge is used in making products (including paint brushes according to its name), as an irritant, in medicine, and for fibers in Belize.

### *Clematis*

(Greek *klematis*, a shoot or vine-branch or twig; named by Linnaeus, but originally used by Dioscorides, fl. A.D. 40–80, for a climbing plant with long and lithe branches)

*Altermannshart* (hard old man [the devil], German)

*ampelomelaena* (*ameplos*, a vine, *melaina*, black, was used by Dioscorides for *Clematis vitalba*, Greek)

*clématite* (from Greek, French); *clematite* (Portuguese)

*hierba de los pordioseros* (beggar's herb, Spanish)

old man's beard (the reference here to “old man” is probably another allusion to the devil)

*skogranke* (*skog*, forest, *ranke*, climber, Norwegian)

traveler's joy (John Gerarde claimed to have coined the name in 1597 when he wrote, “Decking and adorning waies and hedges, where people trauell, and thereupon, I haue named it Traueiler's Iioe”; the name was used later by Williams [1837] 1962)

*tysk klematis* (German *clematis*; introduced, Norwegian)

***Clematis baldwinii*.** Drawn by  
*P.N.Honychurch.*

Virgin's bower (applied to the European climber, *Clematis vitalba* by John Gerarde in 1597; later extended to American species)

*Waldrebe* (woods vine, German); *woudtwijngaert* (wood twiner, Dutch by 1549)

***Clematis baldwinii*** (commemorates the Pennsylvania physician and botanist William Baldwin who died on an expedition to South America in 1819)

[dwarf, marsh] clematis (these have the earmarks of book names; plants do not grow in marshes, and few non-academics call them clematis)  
leather flower

pine-hyacinth ("pine" denotes the typical habitat, in pinelands; "hyacinth," from Greek *uakinthos*, rendered *hyacinthus* in Latin, originally a precious blue stone or simply the color; thus, the name alludes to the pineland habitat and the blue flowers)

virgin bower [virgin's bower]

***Clematis crispa*** (crinkled, referring to the sepals)

blue-bells

blue-jasmine [jessamine]

curl-flower; curly-clematis

[swamp] leather-flower (in use by 1866, and originally referring to *Clematis viorna*, which has thick leathery purple sepals)

marsh-clematis

*Clematis virginiana*

devil's [darning] needles (in used by 1854, but usually applied to insects also called dragonflies); devil's hair (alluding to the tangled stems, Virginia); devil's thread (alluding to the tangled stems)

gander vine ("gander" has meant a male goose since about A.D. 1000; the allusion seems to be that the vines wander aimlessly like a gander, South)

*herbe aux gueux* (beggar or rascal's herb, Quebec)

ladies bower ("ladies" is a form of "Our Lady's," and was in use by the time John Gerarde wrote his herbal in 1597)

leather flower

love vine (a name used for virtually any plant that twines about others)

old man's beard

pipe-stem (perhaps the stems were used in making pipes)

traveler's ivy; traveler's joy (New Hampshire)

Virgin's bower [*virginsbower*] (applied to this species by 1668)

wild hops (comparing it to *Humulus* because both twine, Maine, New Hampshire)

woodbine (originally a European term for *Convolvulus* and *Hedera*, dating to about A.D. 875, and alluding to the tendency of the climbers to wrap around others, Maine)

Europeans and Americans have had mixed feelings about these twining plants. Some obviously consider them sent by the devil himself, as in the names "devil's hair," "devil's thread," and "old man's beard." Presumably, that is because they climb over other plants, but it might be because of their irritant chemicals. Others are enchanted with the elongated, plumose stigmas, and colorful flowers. That view is indicated in names like "traveler's joy" and "Virgin's bower." Many have found the plants medicinal, dating from the 16th century herbalists including Leonard Fuchs (1542), William Turner in 1568, and John Gerarde ([1597] 1975).

*Clematis baldwinii*, endemic to the southeastern United States, was used by Seminoles to treat sunstroke (Small 1933). Cherokee used *C. virginiana* in "Green Corn" medicine, for stomach and kidney problems, and mixed with other plants for backache (Hamel and Chiltoskey 1975). Iroquois used it for venereal sores, kidney problems, and as a wash to induce dreams (Moerman 1998).

In addition to *C. virginiana*, Moerman (1998) listed eight other North American species that have been used from coast to coast. Rafinesque (1830) was among the first Europeans to record American uses for these plants. He recommended an oily liniment for curing the itch, and considered the plant, in minute doses, good for chronic rheumatism, palsy, and ulcers.

Porcher (1863) wrote of *C. crispa*: "This plant is ...employed in secondary syphilis, ulcers, porrigo, etc.; given internally with the powdered leaves applied to the sore. It acts also as a diaphoretic and diuretic... it possesses the properties of the *C. vitalba*, which is a dangerous vegetable caustic, used as a substitute for cantharides, and applied to

rheumatic limbs, and in paralysis and gout. The decoction of the root is alterative and purgative; and is also said to be valuable in washing sores and ulcers, in order to change the mode of their vitality, and to make them cicatrize. Shecut remarks that ‘the Spanish or blistering flies are very fond of the *Clematis crispa*, and it would be well for medical gentlemen in the country to propagate the plant about their residences, in order to secure a constant succession of these valuable insects.’... The American species are deserving of particular attention, and we would invite further investigation of them.”

The reference to “cantharides” and “Spanish flies” are to the soldier beetles (Cantharidae), considered a counterirritant and aphrodisiac since the 14th century (Borror and Delong 1954, Gillott 1980). Alcock (1985) discusses the chemical in association with beetles and their use of it as an antipredator compound.

Porcher (1863) said of *C. virginiana* plants that they had “also a caustic property, and are employed internally as diuretics and sudorifics in chronic rheumatism; and externally, in the treatment of eruptions, and as vesicants...a yellow dye may be extracted from both leaves and branches; the latter are sufficiently tough to make withs and fagots. The fibrous shoots may be converted into paper, and the wood is yellow, compact, and odoriferous, furnishing an excellent material for veneering.” Hocking (1997) added that the species was diuretic, diaphoretic, and used to treat rheumatism and indolent ulcers.

*Clematis* contains acrid, toxic compounds, including anemonin, a dilactone derived from protoanemonin, that are highly irritating to skin and mucous membranes (Lampe and McCann 1985, Diggs et al. 1999). Rafinesque (1830) noted: “Bark and blossoms acrid, raising blisters on the skin; a corrosive poison internally, loses the virulence by cooking.” The French (*herbe aux gueux*) and Spanish (*hierba de los pordioseros*) names referring to beggars are a reference to their past use to irritate the skin to simulate sores and induce sympathy from potential donors (Bown 1995). Ingestion of any part of extracts may cause vomiting of blood, severe diarrhea, and convulsions (Foster and Duke 1990).

### *Clethra*

(Linnaeus adapted the classical Greek name *klethra* for an alder and applied it to this group)

***Clethra alnifolia*.** a. Habit, b. Inner surface of sepal. c. Inner surface of petal with stamens, d. Young style and stigmas, e. Capsule with part of calyx removed. *Drawn by Vivian Frazier.*  
From Correll and Correll 1972.

***Clethra alnifolia*** (alder-leaved)

[spiked, white]-alder (Carolinas)  
puppy-tail [puppytail] (Carolinas)  
*Scheineller* (shining elder, German)  
soap-bush (Carolinas)  
summer-sweet  
[coastal] sweet-pepper-bush [coastal sweetpepperbush]  
white-bush

Linnaeus created the genus for these plants in 1753, although they had been discussed by Plukenet in 1696 and Catesby in 1731. Both Plukenet and Catesby called the trees *Alnifolia americana floribus pentapetalis albis in spicam dispositis* (The American alder-leaved plant, bearing five-petaled white flowers in spikes). So, Linnaeus translated the name “alder” into Greek. There are now 64 species in the genus, most of them in tropical America, but also found in Asia to Malesia (Mabberley 1997).

Moerman (1998) found no records of *Clethra alnifolia* being used by indigenous people. However, the Cherokee are known to have utilized *C. acuminata* as an emetic (specifically for bile). The bark was mixed with bark from wild cherry (*Prunus serotina*)

to lower high fever, and a bark infusion of *Clethra* alone was used to treat bowel problems (Hamel and Chiltoskey 1975, Moerman 1998).

Root decoctions are used as a foot bath for “ground itch”; leaves and flowers are diaphoretic, stimulant, and antipyretic, and applied for pulmonary disorders. The leaves are used to treat inflammations and swellings (Morton 1974, Hocking 1997). Leaves contain considerable amounts of tannin (Porcher 1863).

### *Cnidoscolus*

(Greek *knide*, nettle, *skolos*, thorn or prickle)

*Cnidoscolus stimulosus*. Drawn by  
P.N.Honychurch.

*Cnidoscolus stimulosus* (stimulating, an under-statement!)

bull nettle (“bull” implying potent)

finger-rot (an exaggerated comment on the impact of the stinging trichomes, Carolinas to Florida)

fly-fly (Carolinas)

*hashtapola* [*hashtapoila*, *hatapusha*] (Choctaw)

spurge nettle (“spurge” is from Old French *espurge*, in turn based on *espurgier*, and Latin *expurgare*, to cleanse or purify from impurity; the verb has been in English since about 1303 A.D.; the noun was in use by 1387)

stinging nettle (in use in English by 1525, although it was spelled “styngynge nettylles”; originally applied to European *Urtica*, later to American plants)

tread-softly (an admonishment to be careful of where one walks)

After the Austrian botanist Johann Baptist Emanuel Pohl (1782–1834) traveled and collected plants in Brazil, he returned home and published a book on his discoveries in 1827. That book, *Plantarum Brasiliae Icones et Descriptiones* (Descriptions and Drawings of Brazilian Plants), included one of his more stimulating finds, *Cnidoscolus*. Earlier, in 1813, André Michaux had named the southeastern United States species *Jatropha stimulosus*. It was not until 1845 that St. Louis physician George Engelmann (1809–1884) and Harvard professor Asa Gray realized that the Michaux species belonged in *Cnidoscolus*. There are now approximately 75 species in this American genus, with 4 in the United States (Kartesz 1994, Mabberley 1997).

Seeds and roots are edible (Morton 1968b) but barely worth the effort to obtain them. Murphee (1965) found people in the Panhandle making a tea to “give a man courage” (a sex aid). In the Carolinas, milky sap of the root was mixed with *Smilax laurifolia* and steeped in whiskey or gin to increase male potency (Morton 1974). Porcher (1863) wrote, “It might be employed like the nettle (*Urtica*), as a counter-irritant in epilepsies, and diseases requiring stimulating applications.”

### ***Coccoloba*: Seagrape and Pigeon Plum**

(From Greek *kokkos*, a berry, *lobos*, lobe or pod)

***Coccoloba*.** *Coccoloba diversifolia* (left). *Coccoloba uvifera* (right). Both drawn by P.N.Honychurch.

The name kino sounds like (and is) a card game Mark Twain played in the 1800s while making notes to write *Following the Equator* (Twain [1897] 1992). However, kino is also the plant known in Florida as seagrape (*Coccoloba uvifera*). Apparently, the first usage of the word “kino” dates from 1757, when it was recorded as a medicine by the prominent patron of botanical exploration physician John Fothergill (1712–1780) in his *Medical Observations*.

The first kino used in Europe was “Mandingo kino” or “Gambia kino” from western Africa. Then, in 1774, it was recorded as *gummi kino*. Later, kino came to be a commercial name, applied to several tannin-rich resin-like products, from several species.

'Kino' was described as a substance of brittle consistency and dark reddish-brown color. The material was widely used in medicines, for tanning, as an astringent, and for dyeing cotton. That name was even translated into Spanish as *quino* (Colombia).

Some time later, materials called West Indian kino, or Jamaica kino, or American kino became known. That variety supposedly was taken from what we call seagrape (Florida to Panama). However, it probably was also taken from the pigeon plum (*C. diversifolia*) because few distinguish between those two species.

A more obtuse reference to the same astringent extracts began about 1839, when the material was called false rhatany. The name has also been applied to rattan vine (*Berchemia*, more details are there and under *Krameria*). False rhatany was taken from both *C. uvifera* and *C. diversifolia*.

The first tendency is, however, to compare the fruits of *C. uvifera* with the cultivated grape. Like true grapes (*Vitis*), fruits of *Coccoloba* are purple when ripe and hang in clusters. For example, in the Virgin Islands and Belize *C. uvifera* is simply "grape." In other English-speaking areas, it is seaside grape (Bahamas, Jamaica, Trinidad, Guyana), wild grape, or bay grape (British West Indies).

The comparison with grapes had been made when Captain Gonzalo Fernández de Oviedo y Valdés provided the first record of the seagrape in the early 1500s. He wrote: "The Christians give the name *uvero* to the tree the Indians call *quiabara*." Subsequently, that indigenous name has been rendered *guiabara* and *buibasa*. Oviedo probably was using a Taino name because people still use *guayabón* (big *guiabara*, Dominican Republic) and *guaya-canejo* (Cuba) to refer to *C. diversifolia*. Many of the names for seagrape are also applied to pigeon plum, although there is little doubt that the people using the names know the difference between the two species.

Other people call the trees or their fruits *agraz* (unripe grape, Colombia), *papaturro* (sea grape, Honduras, Costa Rica), *papaturro extranjero* (foreign sea grape, Nicaragua), *uva* (grape, Yucatán, Veracruz, Dominican Republic), *uva caleta* [*uva de galeta*] (coastal grape, Cuba, Dominican Republic), *uva de [la] mar* (sea grape, Tamaulipas, Yucatan, Oaxaca, Puerto Rico, Dominican Republic), *uva de playa* (beach grape, Tamaulipas, Veracruz, Panama, Venezuela, Puerto Rico), *uvero* (grape tree, Tamaulipas, Panama, Colombia, Cuba, Puerto Rico), *uvero de playa* (beach grape tree, Tamaulipas, Veracruz, Panama, Costa Rica, Venezuela), *uva de la costa* (coastal grape), *uvero macho* (male grape), *uvilla* (little grape, Dominican Republic), or *uvita de playa* (little beach grape, Panama, Costa Rica). Pigeon plum is called *uva cimarrona* (wild grape, Dominican Republic), *uverillo* (little grape tree, Cuba, Puerto Rico), *uvilla de sierra* (wild [forest] little grape, Dominican Republic), and *uvilla* (little grape, Cuba, Dominican Republic).

French Caribbean areas also compare the sea grape with the grape. They call the seagrape *squinom raisin bord-de-mer* (wild sea grape) or *raisin [raisinier] du bord de mer* (edge-of-sea raisin tree, Dominica, Guadeloupe, French Guiana), and the fruits *raisin la mer* (sea raisin, Haiti) or *wezen* (raisin, Trinidad). Pigeon plum is called *raisin marron* (wild raisin, Haiti).

Dutch speakers also think the fruits look like grapes. These people say *druif* [*dreifi*, *druifi*] (grape, Dutch West Indies, Suriname), *dreifi de la mar* (sea grape, Suriname), *dreifi die lamán* (sea grape, Aruba, Bonaire, Curaçao), *zeedrieft* [*zeedruif*] (sea grape, Dutch West Indies, Suriname), and *zusterdruif* [*schuster-druif*] (sister grape, Suriname). These same people say that *C. diversifolia* is *dreifi sjimarón* (wild grape, Aruba, Bonaire,

Curaçao) or *paaloe die lamán* (seaside tree, Aruba, Bonaire, Curaçao). No meaning has been found for *bessji die kalakoena* (Aruba, Bonaire, Curaçao).

Some names are unique to *C. diversifolia*. For example, *escobillo de monte alto* (tall, wild little broom, San Luis Potosí, Veracruz, Quintana Roo) is a reference to using the branches for brooms. Mountain grape distinguishes the more inland *C. diversifolia* from the coastal *C. uvifera*. However, unless *palo bobo* (crazy tree) refers to the sometimes complex branching pattern, it is difficult to understand what it may mean.

When I first arrived in Florida I found some seagrape jelly for sale and bought it. On the first taste, I decided that I had been suckered into spending money on apple jelly falsely labeled as seagrape. Only much later did I learn that the two are so similar in taste that few can distinguish them. Some names for seagrape confirming that similarity are *manzano* (apple tree, Sinaloa) and *manzana extranjero* (foreign apple).

Other people make different comparisons, some obvious and others obscure. These names include *aragueque* (from Aragua, Venezuela), *baya de praga* [*boga de praja*] (beach berry), *cumare blanco* (white big bed), hopwood (British West Indies), *Juan garrote* (John thick tree, Colombia), *kiiche* [*kii-che*, *niiche'*, *niiche*] (*nii*, good flavor, *che'*, tree, Maya, Yucatán, Belize), *matora* [*matula*] (Arawak, Suriname), *micongo* (Colombia), *murta* (myrtle, Colombia), *nula* (Cuna), *papalón* [*papatón*] (big potato, Central America), and pigeonwood (British West Indies).

The name pigeonwood crosses over into *C. diversifolia*, which is also called doveplum (Florida, Puerto Rico), pigeon-plum (Florida), and plum-bush (Bahamas). In Spanish, that is rendered *fruta de paloma* (dove fruit, Cuba) or *uva de paloma* (dove grape, Cuba).

Surprisingly, there are comparisons with mangroves. Artist Mark Catesby in 1732 called it the "Mangrove Grape Tree." In Spanish areas seagrape may be *mangle de falda* (mangrove of the edge), while Dutch regions say *mangel die sabbana* (savanna mangrove, Bonaire, Curaçao).

Some names refer to the wood instead of the fruits. These people are impressed with the reddish color and say *C. uvifera* is *carnero* [*camere*] (meat-colored, Mexico), *corralero* (little coral tree, Colombia), horse-wood (British West Indies), or *palo mulato* (mulato tree, Panama). People often do not distinguish *C. diversifolia* and call it red-wood (Dutch Antilles) or *gateado* (color of a cat, a reference to the streaked wood). Oviedo compared the wood to *madroño* (*Arbutus*, Ericaceae) because both use red, but said *C. diversifolia* was stronger. In the early 1500s, people used the wood for houses, butcher blocks, and shoe lasts.

The Glades people used these plants because the pollen has been found in pre-Columbian coprolites from Fort Center on the western side of Lake Okeechobee (Hogan 1978). Moreover, fruits were among those of several plant species offered to Jonathan Dickinson and his party when they were shipwrecked off the Jupiter Inlet in 1699. So, the earliest known inhabitants of Florida used the fruits and most likely the wood.

As much as other people valued the fruits and other parts of the seagrape, there is confusion about whether the Seminoles of Florida used the species. They did, however, use the pigeon plum (*C. diversifolia*). Different individuals used the same names for both species, and it is unclear whether or not they distinguished between them (Sturtevant 1955). The name they apply is *bihcô:bî* (Mikasuki) or *ki:hołákko* [*ki:horákko*] (Creek), both meaning "big mulberry." Because the mulberry (*Morus rubra*) was a tree familiar to

them in their southern Georgia and northern Florida homelands, their designation of *Coccoloba* suggests that they were simply comparing it with an old familiar plant.

Presumably, the Seminoles used the fruits of both species in the same way, although those of *C. diversifolia* need more treatment to be edible. Another common name for the pigeon plum is tie-tongue, an allusion to the abundant tannin in the fruits. That astringency is diminished by drying and rehydrating, and the Seminoles are said to have used that method (Morton 1968b). Fruits of both seagrape and pigeon plum have not only been eaten and made into jelly and syrups, but some have also been made into potent alcoholic drinks.

Wood from both species has been used as fuel and in building cabinets (Little and Wadsworth 1964). Both yield a red dye, colored largely by the tannins. That tannin content has made them useful in medicines, whether called “kino” or not. The roots also are rich in tannins and have been used to treat dysentery. Bark from at least *C. uvifera* has been used as a febrifuge. Seagrape leaves have served as plates or were pinned together with thorns and used as hats.

One of the first Spanish uses was as impromptu paper. Oviedo, writing in the early 1500s, recorded: “At the time the wars were going on in Hispaniola and the other islands and on Terra-Firme, as the Christians did not carry with them paper and ink, they used these leaves like paper. The leaves are thick and green ...and with a pin or sharp point one can write anything on them, from one end to the other... Thus written upon, the leaves were sent by an Indian wherever the Spaniards wished them to go” (translation from Standley 1920–1926).

Although Oviedo told Spaniards in Europe about the seagrape, few other Europeans knew of his report. The oldest records Linnaeus had available when he named the species were two published in 1696 by Hans Sloane and Leonard Plukenet. Sloane called the plants *Prunus maritima racemosa, folio rotundo glabro, fructo minore purpureo* (racemose marine plum, with round glabrous leaves, fruits small and purple). Perpetuating Sloane’s error, Mark Catesby also called the plants “plums,” but Plukenet and Linnaeus knew better. Unfortunately, they really did not know what to make of the trees either. Plukenet called them *Uvifera littorea, foliis amplioribus fere orbiculatis crassis, americana* (seaside American grape, with leaves broad to almost orbicular and thick). Linnaeus in 1753 called seagrape *Polygonum uvifera* and wrote, “*Ex habitu hue retuli (flores non vidi), vel enim hujus generis vel promimi erit*” [From the habit, I retain the species in *Polygonum* (I have not seen flowers), because this genus has prominent nodes].

The generic name of seagrape and its relatives was first created by Patrick Browne in 1756. In his book, *The Civil and Natural History of Jamaica*, Browne introduced Europeans to many plants that were previously unknown. Browne created the genus *Coccoloba*, so Linnaeus simply transferred his own species to Browne’s genus to create *C. uvifera*. Pigeon plum did not become known in Europe until 1769, when it was named by Swiss botanist Nicolaus Jacquin. Now *Coccoloba* contains 120 species, all American (Mabberley 1997).

Humans are certainly not the only ones using the fruits from seagrape and pigeon plum. The common name pigeon plum itself indicates bird usage, and avians also consume seagrape fruits. One of the first years I was in Florida, I was walking along the remains of a tropical hammock beside the ocean in Palm Beach County. I heard a rustling

in the branches in front of me and paused to look. There, sitting on a seagrape branch, was a mockingbird (*Mimus polyglottos*). Something about the bird seemed odd; it was actually swaying unsteadily back and forth on the branch. Then, the gray and white bird reached out and ate an overripe seagrape fruit, and I realized that I had met a drunken Florida native.

### *Coccothrinax*

(Named by Charles Sprague Sargent in 1899 with Greek, *kokkos*, berry, *thrinax*, a fan)

#### *Coccothrinax argentata* (silvery)

*guano* (palm, Taino, Dominican Republic); *palma de guano* (Dominican Republic)

*latanier* [*latangnier*] (*latania* is an indigenous word from Mauritius for a palm there; apparently, this native plant became confused with the one from Africa, Haiti); *latanier* [*balai, d'Afrique*] ([broom, from Africa] palm, Haiti)

*miraguano* (*mira* probably corruption of *lana*, ocean, *guano*, palm, Taino, Cuba)

*palma coyau* (palm heart, Haiti)

silver [palm, thatch] (Florida)

*yarey* (*yerén* [*lerén*], fruit, Taino, Haiti); *yuraguana* (*yerén* [*lerén*], fruit, *guano*, palm, Taino, Cuba)

After collecting plants in the Caribbean, Austrian professor Nicolas Joseph von Jacquin returned to Europe and published his book *Fragmenta Botanica* (Botanical Fragments) in 1801. In that publication, he described *Palma argentata*. It was the early 1900s when Cornell professor and horticulturist Liberty Hyde Bailey (1858–1954) moved Jacquin's species to

***Coccothrinax argentata*.** a. Habit, b. Flowering inflorescence, c. Complete flower (above), flower longitudinally dissected (below), d. Branchlet with fruit, e. Floral diagram of two types of flowers. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982.

*Coccothrinax*. There are now 47 Caribbean species in the genus (Mabberley 1997).

As with most palms, the heart is edible, as are the fruits (Morton 1968b). Oil from the seeds is used in Haiti to “*reavivar el olfato*” (renew the sense of smell) (Liogier 1974). Leaves are used to make brooms. Stems are hard and are used to make pilings in salt water and for fences; leaves are used to thatch houses and to make baskets, ropes, twines, and hats. Stems were used by the early Europeans, and perhaps by indigenous people, for turtle *craals* or corrals (Austin and McJunkin 1978). Scott Zona (personal communication 2003) says that the most important modern application is in making brooms.

### *Cocculus*

(Diminutive of Greek *koccus* or Latin *coccum*, a scarlet berry, and *-ulus*, the diminutive; an old name, thought to be a source of dye, which turned out to be from cochineal insects on the berries rather than the fruits themselves)

#### ***Cocculus carolinus*** (of Carolina)

coral-[beads, berry, vine] [coralbead, coralberry]  
*hierba de ojo* (eye herb, Coahuila, Tamaulipas)

margil (English?)

[Carolina, red-berry, red] moonseed (according to the OED 1971, the “moonseed” is a translation of the Latin and was first used by Philip Miller in the *Gardeners Dictionary* of 1739)

[Carolina] snailseed (compared with a snail because of the coiled seed)

The first European mention of what we now call *Cocculus* was in 1753. That year Linnaeus published *Species Plantarum* and wrote, “*Menispermum carolinum, foliis cordatis subtus villosus. Habitat in Carolina*” (*Menispermum* from Carolina, with cordate leaves villose below. Grows in Carolina). That is all most people know about this twining species.

It was not until 1817 when Augustin-Pyramus de Candolle created the genus *Cocculus*. Both genera belong to the Menispermaceae, a family notorious for species used in curare, fish poisons, sweeteners, and contraceptives (Mabberley 1997). The family is famous for containing sesquiterpenoids that act as poisons. However, little seems to be known about the North American members and Hardin and Arena (1974) simply say “may be poisonous.” Perkins and Payne (1978) did not add much, but they make it clear that the related species *C. laurifolius* in southeastern Asia contains alkaloids cocculidine, coclaurine, coclamine, coclifoline, coclifoline, laurafoline, and trilobine. Of these, coclaurine is a curare-like compound. Hocking (1997) adds that it contains benzyloquinoline derivatives. It seems likely that the species in the eastern United States contains many of the same chemicals, but no cases of poisoning have been recorded.

These vines grow in the heart of Muskogean territory in the southeastern United States. Plants range from North Carolina to northern peninsular Florida, west to Kentucky, southern Missouri, eastern Oklahoma, and Texas. Rhodes (1997) says they also grow in Mexico, maybe Coahuila or Chihuahua, but he does not say which state.

Given the poisonous nature of most members of the family, it would be best to heed Hardin and Arena’s (1974) warning that they might be poisonous. Standley (1920–1926) said that the fruits were edible, but Correll and Johnston (1970) made it clear that they “had not tried them.” Because the Choctaw used the berries to poison fish (Swanton 1946), eating them would not be advisable. Swanton’s informant Jackson Lewis also pointed out that in catching fish, they poisoned a pool with berries but cut down bushes and piled them about it to keep livestock away and cautioned their people not to drink it. Eventually, when the Choctaw began raising European-introduced cattle and chickens, they stopped using the berries for beads because they were afraid they would kill those domestic animals (Swanton 1946).

The only other notation found is among the Houma who used the root to make a drink taken as a blood clarifier (Speck 1941). However, in the south-western United States, *C. diversifolius* is used identically with *C. carolinus* (Hocking 1997). Brazilians use *C. filopendula* to promote menstruation and to treat liver and bladder afflictions and snakebite (Lewis and Elvin-Lewis 1977, Mors et al. 2000).

*Collinsonia*

(Named for Peter Collinson, 1694–1768, a London cloth merchant and naturalist who used his overseas agents to provide plants for his and his friend’s gardens)

***Collinsonia canadensis*.** From Britton and Brown 1897.

***Collinsonia canadensis*** (of Canada)

archangel (named for St. Michael the Archangel, who held the highest rank among angels; the name has been applied to a number of mints since about A.D. 1000, presumably for their medical uses)

citronella (alluding to the strong lemon fragrance, resembling citron, *Citrus medica*)

Collinson’s flower

[broadleaf, Canada] *Collinsonia* (book names)

gravel-root (applied to *Eupatorium purpureum* by 1866; the name reflects treatment of kidney or bladder stones; “gravel” has been applied to urinary crystals since ca. 1400)

hardtack (figuratively “hard-fare”; a name applied to a ship-biscuit by 1841; probably derived from “hard-bread,” which began to be used as a biscuit in the 1400s)

heal-all (anything considered a universal remedy, a panacea; in use by 1577 as a term for plants and other medicines)

horse balm (see horse-weed); horse-weed [horse-weed] (explained by John Bartram in 1751 as “not only because horses are very greedy of it, but it also is good for sore gall’d backs”; Kalm added in 1753 that it had that name because “horses eat it in spring, before any other plant comes up”)

knob grass [knobgrass, knob root, knobroot, knob weed, knobweed] (all names alluding to the knotty roots)

mountain-balm (akin to the name mountain-balsam or *Abies*, but alluding to use in external medicines, Virginia)

ox balm (see horse-weed)  
 rattlesnake-root (recorded by John Bartram in the 1740s, West Virginia)  
 richleaf; richweed (said to have been given because of the strong lemon fragrance; in use by 1830)  
 stone root [stoneroot] (two versions exist for the application of this name; one is that it was applied because of the stone-hard rhizome; the other is that it came to reflect use in treatment of kidney or bladder stones)

***Collinsonia serotina*** (late-flowering)  
*citronelle* (because of lemon scent, French)  
 horse balm  
 richroot  
 stone root

*Collinsonia* is an endemic North American genus of four species (Kartesz 1994, Mabberley 1997). The original specimen of *C. canadensis* was sent to Peter Collinson by John Bartram in 1735. Collinson sent the specimen to Gronovius and then it was used by Linnaeus in his *Hortus Cliffortianus* of 1738 where he coined the genus *Collinsonia*. The surveyor-general of New York, Cadwallader Colden (1688–1776), used the name *Collinsonia* in his *Plantae Coldenhamiae in provincia Noveboracensi Americes sponte crescentes* (Plants Collected by Colden in the Provinces Where They Grow in North America), published in 1743.

The Cherokee used *C. canadensis* on swollen breasts and as an emetic, and they used mashed flowers and leaves as a deodorant (Hamel and Chiltoskey 1975, Moerman 1998). The Iroquois applied leaves to stop headache, to treat diarrhea, rheumatism, the blood, boils, heart trouble, and kidney problems, and as a bath to strengthen children (Moerman 1998). John Bartram recorded that Conrad Weiser, his interpreter when he visited the Onondaga in 1743, had been told that the Onondaga used the plants to counteract rattlesnake bites (Berkeley and Berkeley 1982, Coffey 1993).

Rafinesque (1830) also commented on *Collinsonia*. He called it “richweed,” and said indigenous people used it in a tincture to heal wounds. People in Appalachia make a tea from the plant and use it to treat headache, cramps, and indigestion (Krochmal and Krochmal 1968). Hocking (1997) considered it diuretic, diaphoretic, astringent, a tonic, and an expectorant, and useful in treating hemorrhoids.

Perhaps no distinction is generally made between species because *C. serotina* has some of the same names as *C. canadensis*. Hocking (1997) wrote that it was used as tea (“French tea”), and was medicinal (Hocking 1997).

These medicines are not without potential problems. Peter Kalm ([1753–1761] 1972) said that *C. canadensis* “has a peculiar scent, which is agreeable, but very strong. It always gave me a pretty violent head-ach [*sic*] whenever I passed by a place where it stood in plenty, and especially when it was in flower.” Foster and Duke (1990) warn that minute doses of fresh leaves may cause vomiting. Hocking (1997) attributes those reactions to volatile oils, resins, and mucilates. Still, Duke et al. (2001) gave *C. canadensis* two plus marks, indicating it is as safe as a cup of coffee.

***Colubrina*: Snakewood**

(From Latin *colubrinus*, like a serpent, alluding to the stems or stamens)

My former student, now a working anthropologist, had surveyed one region of the Big Cypress for archaeological sites used by indigenous people. In one hammock, he had found a tree that he did not recognize. The area was covered with historical and pre-European materials and had been used by more than one ethnic group, including the Glades and Seminole people. He suggested we visit the hammock to check on the unknown tree. As we walked across the wet prairie, mostly dry in this season, we talked about the area we were going to visit and some of the surrounding region.

Climbing up a slight rise into the hammock we had to dodge piles of cow dung and bones, because a herd of Seminole cows was roaming the fields and forests. We stopped at the tree my friend said had stumped him. At first, I too was at a loss as to its

*Priscilla Fawcett*. From Correll and  
Correll 1982.

identity. The branches were limber and the egg-shaped leaves were coated with red pubescence on the lower surface. I kept running through my mind the possibilities from this area southwest of Lake Okeechobee in Hendry County. Then, I realized what the plant was. I said to him, "Well, if I were in Everglades National Park, I would call this *Colubrina arborescens* or snake-wood."

The other areas where I had seen this species were far to the south of this spot. According to the books, this species did not grow this far north (Little 1978). Obviously, this tree had not read the books because it was growing about 50 miles north of its known range. The species is tropical, and only within the temperature-moderating hammock forest where it grew could it withstand the freezes of this region.

Typically, this snakewood was known from southern Miami-Dade County on the mainland, the Florida Keys, the Bahamas, and the West Indies as far south as Barbados. Plants are also found in Central America, but they are said to have been introduced and primarily grown for shade from Yucatán through El Salvador and Honduras to Guatemala (Morton 1981). There are herbarium records of the species also extending south into Colombia, Ecuador, and Peru.

Several other species of *Colubrina* are in southern Florida, all on the northern fringe of their tropical ranges. Some of the species are so rare in the United States that they are considered endangered. *Colubrina arborescens*, *C. cubensis*, and *C. elliptica* are among those considered endangered within the United States (Coile 2000). Miami-Dade, Collier, and Monroe Counties are the regions where those endangered plants were formerly known. My student and I were looking at one of the endangered trees far north of those counties.

The name snakewood has a complicated history, and it is not clear whether or not the common names gave rise to the scientific, or vice versa. However, I suspect the name snakewood is much older. Apparently, the first recorded association with snakes was in 1760 with Nicolaus Jacquin. In his book *Enumeratio Systematica Plantarum* (Systematic Enumeration of Plants) he described plants now called *Colubrina ferruginea*. However, Jacquin did not call them that. Instead, he thought they belonged in another genus and called them *Rhamnus colubrinus*. The temperate genus *Rhamnus* was known to this Swiss botanist, and he did not realize that those he studied in the Caribbean were generically distinct. It fell to two French botanists, Louis C.M. Richard and Adolphe T. Brongniart (1801–1851), to create a new generic name for this red-pubescent plant and its relatives. This pair called these plants *Colubrina*, basing the name on the *Rhamnus colubrinus* of Jacquin.

No one is sure whether Jacquin meant to note the snakelike sprawling stems of the plants or their stamens (Quattrocchi 1999). There is nothing about the stamens that appears snakelike to me, but the stems do twist and turn in a way that might cause someone to think of a snake. Charles S. Sargent (1905) suggested that the name probably was given "on account of the peculiar twisting of the deep furrows on the stems of some of the species." Tomlinson (1980) agreed with Sargent and added that "the name was Latinized as *Arbor colubrina* (serpent tree) by early botanists."

Even today, the plants are called common snake-bark (Bahamas), snake-bark (Puerto Rico), or snake wood (USA, Jamaica). The related species *C. elliptica* is called smooth snakebark (USA, Puerto Rico) or snake root (Virgin Islands). Curiously, no names in any other language make reference to snakes.

Some of the names compare snakewood with other known plants. For example, in Puerto Rico it is called *abeyuelo* [*abeuello*, *abuejuelo*]. That suggests that it resembles the *abey*, a tree known scientifically as *Jacaranda bahamensis* (Bignoniaceae). Both are favored herbal medicine sources. In Cuba, snakewood is sometimes called *achiotillo* (little achiote or *Bixa*) or *bijáguara* [*birijagua*] (*bijá* is *Bixa* in Taino). Both names compare the plants to *Bixa orellana* (Bixaceae). *Bixa* is the source of a medicinal red dye that is now used throughout the tropics. Snakewood has also been called wild ebony (Jamaica) and mountain ebony (Jamaica).

Several of the names indicate substitution for other plants, such as coffee colubrina (USA, Puerto Rico) and wild coffee (USA). As the plants have been used as soap substitutes, it is not surprising to find them being called scrubbing bush (British Antilles), soap bush (Bahamas), soap tree (Puerto Rico), and soapwood (Bahamas). Uses in treating digestive problems are surely shown by names like bitters (Bahamas) and *palo amargo* (bitter wood, Dominican Republic). Several species are said to be bitter, antiscorbutic, stomachic, tonic, laxative, a febrifuge, and a vermifuge (Roig 1945, Morton 1981). The bark contains saponins, particularly colubrinoside, and alkaloids (Colard et al. 1976).

Another curious name for the genus is nakedwood (USA). I have seen the plants in all seasons and even in droughts. Never have I seen them lose their leaves, so they could not be called “naked” because of that. The application dates to at least the late 1800s. Perhaps the genus was named because of plain wood. Sargent (1905) described the wood of *C. elliptica* as “heavy, hard, very strong, dark brown tinged with yellow, with thin light yellow sapwood.” Almost the same description is given for *C. arborescens* by Little and Wadsworth (1964) and they commented that both species are used for posts. Formerly, *C. arborescens* was used as pilings because it was resistant to decay in water. Little and Wadsworth (1964) add that the specific gravity of *C. arborescens* is 0.7 and of *C. elliptica* is 0.8. That density probably explains why the plants were called *bois de fer* (iron wood, Haiti) and *bois fer blanc* (white iron wood, Haiti).

Other names for *C. arborescens* are black velvet (Jamaica), *corazón de paloma* (dove heart, Dominican Republic), *cuerno de buey* (ox’s neck, Dominican Republic), *fuego* (fire, Cuba), and greenheart (Jamaica, Puerto Rico, Barbados). Of all the names, surely the most curious is *trejo* (Dominican Republic). This name seems to apply to a table shot in *trucos*, a game resembling billiards. Perhaps the balls are made from the wood of this tree. Black bead tree (Barbados) is the only name found that refers to making necklaces and other ornaments from the seeds.

*Colubrina* is a genus with rampant taxonomic uncertainty. Some sources (e.g., Standley 1922–1926) say that *C. arborescens* is not present in Central America and Mexico, but that the species there is actually *C. greggii*. These two names represent species so similar that they are not easily distinguished, at least in herbarium specimens. For example, the Missouri Botanical Garden database (TROPICOS) and the herbarium in Mérida, Yucatan, both have specimens listed as both species.

The situation is complicated by the fact that the “real” *C. arborescens* was brought into southern Mexico and Central America for cultivation long ago (Morton 1981).

Whether wild or cultivated, there is a series of local common names for this species. Surely related to the cultivated plants is the name *chaquira* [*chaquirio*] (El Salvador), which alludes to an ancient vessel (*abalorlos*) that brought the Spanish to the Americas to trade with indigenous people. Perhaps the cultivation of the trees in Central America dates from the time of that ship.

In Chiapas, Mexico, the trees are called *cascalote* [*cascalata*] and *cascarillo*. Those names allude to the medicinal bark and also perhaps to its use to adulterate *cascara sagrada* (*Rhamnus purshiana*), a famous laxative from western North America. Since *cascara sagrada* is loaded with anthraquinones, as are several other members of the genus, perhaps *Colubrina* also contains those chemicals. This species is in turn related to *Rhamnus frangula* of Eurasia and the Mediterranean, which itself has a long history of purging inhabitants of the Old World (see *Rhamnus*). Probably related to *cascarillo* is the name *churumai* (Campeche); *churumo* is juice from something, alluding to a medical use.

Other names suggesting medical use include *guayabillo* (little guava, Guatemala), *pimiento-che'* (pimiento tree, Yucatán), and *tzecui* (Zoque, Chiapas). Both guava and canella remain useful for treating several maladies.

Two names recorded from Guatemala seem to be Mayan—*costex* and *coxté*. Because dialects of that language vary considerably the meaning cannot be certain, but an apparent cognate appears in the Maya of Yucatan. The infinitive of that word is *koxok* (to tie with cord). To *koxtik* is to tie something, and *k'oché'* is a bed or platform on which ill or deceased individuals are carried. It seems the flexibility and resistance of the wood make it useful in constructing these beds and also in constructing the framework for roofs on buildings covered with palm leaf thatch. Those uses do not seem to be recorded elsewhere for the genus, and they illustrate the ethnobotany often hidden in common names.

### ***Colubrina*: Soldier-Wood or Mabi**

(See preceding entry for etymology)

Of all the Caribbean region members of *Colubrina*, the most famous is *C. elliptica*. That species is usually called *mabi* [*maabee*, *mabie*] in Puerto Rico, Haiti, and the Dominican Republic. There are variants of that name in several places, including *mabee tree*, *mambee* (Guadeloupe), *maubee* (Virgin Islands), *mawbie* (Lesser Antilles), *palo [de] mabi* (Puerto Rico), *mabit* (Haiti), and *bois mabi* (*mabi* tree, Haiti, Dominican Republic, Guadeloupe). Everything we know about that common name indicates a Caribbean origin, and it is a Taino word. A comparison with other Arawakan words is instructive. For example, “remedy or medicine” in Arawak is *ibihi*, and in Karina, the Cariban language spoken in Suriname, it is *e:pit*. In Island-Carib, medicine is *ibie*. All those words are close enough to *mabi* that they could be cognates.

Anyone who has visited the island of Puerto Rico has seen stands along streets where *mabi* is sold. The bark is steeped in water to make a cooling drink, *mabi* or *mabi champan*. Alternative common names for this drink are *amargo* (bitter, Dominican Republic) or *palo amargo* (bitter wood, Dominican Republic).

Inhabitants of the Caribbean considered this beverage a tonic and antidote for indigestion and dysentery. Coll y Toste (1972) comments, “*Su hoja sirve en Puerto Rico*

*para hacer una bebida refrescante, tónica, de uso generalizado. Viene a ser la cerveza criolla*" (Its leaf serves in Puerto Rico to make a refreshing, tonic beverage of general use. It is becoming the Creole beer). The plants have many other uses. Because the bark is resinous, astringent, and bitter, a decoction is applied in Mexico to pimples and itching skin (Morton 1981). In Cuba, it is taken as a febrifuge and a remedy for liver and pulmonary diseases, dysentery, gonorrhea, and syphilis (Roig 1945). The leaf decoction is taken in Cuba as a treatment for fever, diarrhea, and dysentery. That preparation also serves as a vermifuge and an emmenagogue, and it is applied to ulcers of the gums. Names associated with the treatment of diarrhea include seaside buckthorn and wild guava (Cayman Islands).

A factory on Curaçao made *mabí* beverage, and Morton (1981) gave details of its manufacture. Bark is shipped to the island from farther north. This bark is brewed with cloves and brown sugar, and the froth is skimmed from the surface. A "starter" (small portion) from a previous batch is added to the new preparation to encourage fermentation. The decoction is left standing for 1 day, skimmed again, and then bottled but not capped. If closed, the bottle will blow off the cap because of the accumulated fermentation products. The product is much appreciated locally as a refreshing drink and a bitter tonic, as it is farther north in the Caribbean.

Few chemicals in the plant have been studied, but it is known that the leaves are high in tannin and the bark is high in saponins. A major component is the saponin mabioside (Seaforth et al. 1992, Oulad-Ali et al. 1994). The bark also contains a bitter chemical called colubrinin. Surely, the species contains colubrinol and colubrinin, which have been found in related species (Wani et al. 1973, Colard et al. 1976a, b).

The name soldier-wood (USA) is perplexing. The combination of the word "soldier" with plants and animals has been made since at least the first part of the 1800s, but the other cases recorded are plants that have some red or purple coloring. The oldest instance with animals is soldier-insect, which dates from 1699. Other names applied to animals are from the 1800s. For example, there is soldier-beetle (1855), soldier-ant (1857), soldier-bird (1857), soldier-fish (1880), and soldier-moth (1880). The first records of soldier-wood were from the 1820s and applied to the legume *Calliandra purpurea*.

Sometime between the 1820s and the early 1900s, the name soldier-wood was applied to *Colubrina elliptica*. The fruit is the only thing about this plant that is red or purple and that would cause people to use the term soldier in the name. Perhaps that is the reason for the name. On the other hand, could it be a reference to medical use by soldiers?

There seem to be three basic uses of *mabí* in addition to the drink—soap, wood, and charcoal. In Mexico, the plants are called *amole* (soap, Náhuatl, San Luis Potosí). There and throughout the range of the species, from southern Florida, the Bahamas, West Indies, Veracruz to Yucatan, Mesoamerica, and northern Venezuela, the leaves are a soap substitute (Morton 1981).

Several common names refer to the wood. These include *bois costiere* (coastal tree), *bois de fer* (iron wood, Haiti), *palo de arco* (bow tree), *palo de hierro* (iron wood), *madera de hierro* (iron wood), and *guitarán* (big guitar, Puerto Rico). The references to iron allude to the hardness of the wood, which is also heavy, with a specific gravity of 0.8. The wood has the reputation of being durable and has been used for posts, among other things (Little and Wadsworth 1964).

Another name that is somewhat obscure is naked-wood (USA, Puerto Rico). Tomlinson (1980) thought this name was given because the bark of older trees peels off in strips. However, the name may allude to the wood color since there are similar references in other languages. In Puerto Rico, the plants sometimes are called *catire*. That word is a name for a pale-skinned person resulting from a cross between a white and mulatto. In Cuba, it is *jayajabito* [*jayajabico*]. Although the etymology is uncertain, it may be a combination of Taino *yaya* and *jabiya* (*Hura crepitans*). *Yaya* is the Taino common name of annonaceous *Oxandra lanceolata* and also colloquial Cuban for “become pallid.” Thus, it would be the pale *Hura*.

The Maya of Yucatan make the most vivid allusion with *sacna-che'* [*sak-nak-che'*] (*sak*, white, *nak*, intestines, *die*, tree). That name is given because the *Colubrina* climbs through neighboring plants and the stem is the color of intestines.

Names such as *carbonero* (charcoal tree, Cuba), *carbonero de costa* (coastal charcoal tree, Cuba), and *palo carbonero* (charcoal tree) indicate the hard wood is made into charcoal. Charcoal is often in demand as fuel in many parts of the Caribbean, Mexico, and Central America.

To avoid confusion, the correct scientific name of the *mabí* is *Colubrina elliptica*. That name is based on *Rhamnus elliptica* given to these plants by Swedish professor Olaf Peter Swartz in 1788. Unfortunately, another name (*Ceanothus reclinatus*) was given to the plants that same year by the celebrated French magistrate and botanist Charles-Louis L'Héritier de Brutelle (1746–1800). Because of confusion or misinterpretation, L'Héritier's name was thought to be correct. The name used in the older literature is *Colubrina reclinata*. In some sources, the two are considered distinct species. It was only in 1958 that George K. Brizicky (1901–1968) and William L. Stern realized this complication and made the name *C. reclinata* synonymous with *C. elliptica*.

This *Colubrina* has the most restricted range of the species in Florida, being confined to small areas of hammocks in southern Miami-Dade County and nearby Monroe County. To see the species it is best to go to preserved areas on upper Key Largo. There, or on one of the wilder sites like Adams Key in the Biscayne National Monument, it is possible to find these trees reaching 50 feet in height. Their dark bark flakes off in large patches, and the inconspicuous yellow flowers turn into orange-red fruits. Those fruits are easily noticed against the green of the canopy by a variety of birds.

Given its restricted range in Florida, and the fruits that are probably dispersed by birds, we must wonder how the trees came to be there. Perhaps the seeds were carried by birds since they flower and fruit with little regard to season. However, knowing the value the Caribbean people place on the plant as a medicine and beverage, one has to wonder. There was a long history of Cuban and Bahamian plantations along the coasts of southern Florida during its early history. Could people on one of those plantations have brought the plants for local usage?

### *Commelina*

(Commemorating three Dutch botanists of the name Commelin or Commelijn; Linnaeus said that the two blue petals of the original species reminded him of Jan, 1629–1692, and

his nephew Kaspar [Caspar, Casparus], 1667–1732; the small white petal reminded him of a third relative who died young)

*comméline* (French)

*Himmelsauge* (heaven vessel, German)

***Commelina erecta*** (upright)

bluebird (a Creole name, Nicaragua)

*canutillo* (widespread Spanish name for the genus, maybe “little cane,” from *caña*)

[white-mouth] day flower [whitemouth dayflower] (alluding to the duration of each flower, USA); dew-flower

*espuelitas* (little spurs, Coahuila)

*hierba de pollo* (chicken herb, Texas)

little bamboo (Belize)

*mataliste* [*mataliz*, *matalis*] (maybe from *mata*, plant, *lisa*, smooth, used for several members of the Commelinaceae, Tabasco, El Salvador)

*okí ahissí* [*oybá ahissí*] (water [*oybá*, literally “rain”] medicine, Koasati)

*pah-tsá* (*pah*, something bitter, *tsá*, to mix in, perhaps because the *Commelina* is mixed in

***Commelina erecta*.** Drawn by  
*P.N.Honychurch.*

with maize dough to aid fermentation in the preparation of *pozol*, Maya, Yucatán)

*tamakusi* (Carib, Suriname)

*utek'* (Huastec, San Luis Potosi)

*x-habul-ha* (*ha*, water, *bul*, submerge, Maya, Yucatán)

*ya'ax-ha-xiu* (*ya'ax*, green, *ha*, water, *xiw*, herb, Maya, Yucatan)

***Commelina virginica*** (of Virginia)

[Virginia] day-flower [dayflower] (R.Holme wrote in 1688, "The Virginian Spiderwort...may be called the Day Flower, for it opens in the day and closes in the night")

dew-flowers (maybe a comment on the nectar within the bracts)

When Linnaeus created the genus *Commelina* in 1753, he included nine species, although not all of those are now retained in the genus. None of those he knew is native to Europe; they come instead from the Americas, Africa, and Asia. The genus now has about 170 species growing in the tropical and warm parts of the world (Mabberley 1997).

P.P.Sheehan in 1912 (in von Reis and Lipp 1982) and J.K.Small (1933) were told that the Seminoles use the sap of *C. erecta* to soothe irritations even though it contains oxalic acid crystals that may be highly irritating to mucous membranes (Lampe and McCann 1985). Sturtevant (1955), Bennett (1999), and Snow and Stans (2001) were unable to find them still using the plants. The Huastecs of Mexico use the water trapped in the inflorescence bracts for eye problems (Alcorn 1984), and the plant is used in a similar way in Bolivia (von Reis 1973) and Belize (Balick et al. 2000). Kimball (1994) thought the Koasati formerly used it in tanning leather.

There has been so much confusion between *C. elegans* and *C. virginica* that it is likely both have been used similarly. A decoction is considered diuretic and is used for intestinal problems and to staunch the bleeding of surface wounds (Hocking 1997).

***Conocarpus*: Buttonwood**

(From Greek *konos*, a cone, and *karpos*, fruit)

*Conocarpus erectus*. Drawn by  
P.N.Honychurch.

When I first arrived in Florida from the midwestern city of St. Louis, Missouri, I had read about “driftwood” and seen it for sale in shops. Those gnarled pieces of wood sold for high prices in the Midwest, and it had been something of a mystery to me where the wood originated. Not long after arriving in the state, I made a pilgrimage to the Florida Keys, where the answer to that old mystery was revealed. In several places along the road south, there were shops with stacks of “driftwood.” I even found men in pickup trucks harvesting the wood from the edges of mangroves—driftwood and buttonwood were the same *Conocarpus erectus*. On one occasion, my class and I helped a man extract his truck from the mangrove mud where he had been stuck for some hours. The bed of his truck was loaded with several hundred pounds of buttonwood root systems and stumps. We never learned exactly what the harvesters were paid for the products, but it was markedly less than the selling price in St. Louis.

In the Romance languages, the name of a flower bud is a *botón* (Spanish), *botão* (Portuguese), *bottom* (Italian), or *bouton* (French). These are supposedly based on Latin *bottare*, meaning “to thrust or put forth.” That sense is much older than in English where it came to mean that about A.D. 1400. Older in English is the meaning of a “fastener.” That idea has been traced to about A.D. 1340. In English, linking the word “button” with a plant name has been traced to about 1598.

Still, when someone now says “buttonwood,” are they talking about the fastener or the globose cluster of flower buds? Few would even be aware of the connection between buds and buttons.

In the past, buttons were not always flat objects. Button shapes have varied over the centuries, with the older kinds tending to be globose; those of more recent derivation tend to be flattened. Just when the tropical trees now called buttonwood received that name is unknown, but the usage surely must go back to the early 1600s. Yet, looking at the names

given to the plants before we began calling them *C. erectus* in 1753, one might not suspect the antiquity of the common name.

Probably the first reports of the trees in the New World were published in 1696. That year Leonard Plukenet called them *Alnus maritima myrtifolia coriariorum* (the oceanside alders with leathery myrtlelike leaves). The same year, Hans Sloane, in his book on Jamaica plants, also called it an alder, but Linnaeus realized that the plants were not that similar to *Alnus*. To make a unique place for them, Linnaeus created a new generic name, *Conocarpus*. The fruit cluster is globose, but Linnaeus dissected out the individual parts and saw that each flower in the group had produced a cone-shaped mature ovary. Presumably, he was talking about the upright stance of the trees when he named the species *erectus*. By modern international rules of nomenclature, all scientific names must be based on a “type” (permanent reference point for identification). Sloane’s drawing (plate 161, figure 2) published in 1725 in his second book, *A Voyage to the Islands Madera...and Jamaica*, is the type for buttonwood.

People who use common names are often not aware of scientific appellations. Most people either allude to the buttonlike nature of the flower and fruit clusters, or to the fact that the trees are mangroves, or both. Some of the names noting the buttons are black buttonwood, *botoncahui* (button tree, mixture of Spanish, *botón*, and Náhuatl, *cahuítl*, Sinaloa), *botoncillo* (little button tree, Puerto Rico, Dominican Republic, Veracruz, Chiapas, Yucatán, Belize, El Salvador, Venezuela), button alder, button bush (Belize), button mangrove (USA), button tree, button-wood (Florida to Virgin Islands, Panama), *palo botón* (button tree), silver buttonwood (Florida), and white buttonwood (USA). Those comparing them to buttons and mangroves say *mangle [de] botón* (button mangrove, Puerto Rico, Cuba, Panama), *mangle botoncillo* (little button mangrove, Campeche, Venezuela, Puerto Rico), *mangle botón* (button mangrove, Puerto Rico), or *mangue de botão* (button mangrove, Brazil). Surely, *mangle garbancillo* (little bean [garbanzo] mangrove, Colombia) also belongs in this group.

Those comparing the trees with the other mangroves often use colors. Some think the trees should be white and say *estacahuíte [estachahuíte]* (*iztac-cahuítl*, white tree, Náhuatl, Oaxaca), *mangel blanco [mangel blancu, manguel blancu]* (white mangrove, Aruba, Bonaire, Curaçao), *mangue bronco* (white mangrove, Brazil), white mangrove (Belize), and *witt mangel* (white mangrove, Dutch Antilles). Others think the trees should be gray and call them *grize manguel* (gray mangrove), *grijze mangel* (gray mangrove, Aruba, Bonaire, Curaçao), *mangle cenizo* (ash mangrove, Oaxaca), *mangle gris* (gray mangrove, Guadeloupe, Martinique), *manglier gris* (gray mangrove, Guadeloupe, Martinique), and *paleuvier gris* (gray mangrove, Guadeloupe, Martinique). Still others think they should be black and say *mangle negro* (black mangrove, Costa Rica, Oaxaca) or *mangle prieto* (black mangrove, Dominican Republic, Tabasco).

Some make no reference to colors but simply say *mangel* (mangrove, Dutch Antilles), *mangle* (mangrove, Sonora, Campeche, Guerrero, Dominican Republic), *manglier* (mangrove, St. Lucia), *mangue* (mangrove, Brazil), *manguel* (mangrove, Dutch Antilles), or *paleuvier* (mangrove, Haiti).

Other names note that the trees are mangroves but indicate some association other than color. There is *mangle jeli* or simply *jele* (Ecuador), *mangle lloroso* (crying mangrove, Venezuela), and *mangle torcido* (twisted mangrove, Panama). The most complex of the group is *mangle marequito* or just *marequito [mariquito]* (Costa Rica). The word

*mariquito* has several meanings. Three of the meanings seem to have nothing to do with these trees. Those are a black and red hemipteran, locally called *vaca de San Antón*; a climbing parrot; and in Cuba, *miel con almibar con queso fresco* (honey with carmel with fresh cheese). Finally, it is simply translated as “mangrove.”

The Seminoles of Florida claim uses for only the buttonwood, although they have named all the other mangroves (Sturtevant 1955). The Miccosukee call this tree *ahilo:chiskoposki*, and their relatives the Creeks say *tolastisilopócki*. Both names mean “small leaved black tree” (*eto*, tree, *esse*, leaf, *lopocke*, small, *lvste*, black). The Seminoles used the plants to dye buckskin and the wood in fires to barbecue meat. All who know the plants consider the wood of high quality for fuel.

Down on the Yucatán peninsula and Belize, the Maya also have names for the trees. Instead of making the color comparisons other people use, they sometimes say trees are the *xkan-che'* [*canche*, *kanche*, *k'ank-che'*, *k'ank-ank-che'*, *k'an-inche*, *x-kanche'*] (*ka'an*, yellow, *che'*, tree). An equally common name they use is *tabche'* [*taabche'*, *x-tabchéem taabche*, *tabche'*] (*taab*, fixed or steady, *che'*, tree). The Mayans give the tree this name because they find the trees well established by their roots in muddy soils of the mangroves.

In Mexico, some say the trees are the *madre de sal* (mother of salt, Oaxaca, Chiapas). That name apparently alludes to the deposition of salt on the bases by seawater evaporation. In Panama and Colombia, buttonwood is called *saragoza* [*zaragosa*] (*Zaragosa*, the capital of Aragon, Spain). No reason for comparing the trees with that city has been found. Finally, in Cuba buttonwoods are called by their Taino name, *yana*.

Buttonwood has an extensive range. It is found in Florida, Bermuda, the Bahamas, West Indies, on both coasts of northern Mexico, south to Panama, and also on the coasts of South America. This is one of the comparatively few species that also occurs in West Tropical Africa. Pond apple (*Annona glabra*) is another of those species (See *Annona*: Pond Apple), and many think that the distribution of both species was by seawater dispersal.

The wood has been used for rafters, boats, and cabinets. Posts made from buttonwood are durable in the soil, whether wet or dry. Leaves and bark have been used throughout the range for tanning leather. In the Virgin Islands, buttonwood has been used as a fish poison (Petersen 1974). In Mexico, the bitter bark is used as an astringent and tonic medicine; it is applied to prickly heat in the Bahamas (Martínez 1969, Morton 1981). Brazilians take the fragmented bark and leaves and boil them together, strain them, and give them sweetened to weak, anemic, and convalescing individuals (Morton 1981). Cubans have given the dried powdered bark in a more palatable beverage to reduce fever (Roig 1945).

Charcoal making has been the most common use for buttonwood throughout its range in the Americas. Although few people have seen them, there were formerly great mounds in southern Florida where people had made charcoal from the wood of button-wood (Tebeau 1955, 1966, 1968). The last charcoal mounds I found were in the Flamingo area of Everglades National Park and on Chokoloskee Island in Collier County. Those mounds in Collier County have now been replaced by trailer courts and houses.

***Conoclinium***

(From Greek *konos*, a cone, and *klinion*, a little bed, referring to the receptacle)

***Conoclinium coelestinum*.** a. Habit, b. Flowering head. c. Receptacle with one flower, d. Anthers. *Drawn by Vivian Frazier. Correll and Correll 1972.*

***Conoclinium coelestinum*** (sky blue, the flowers) (= *Ageratum conyzoides*)

blue mistflower

*bouton blanc* (white bud, Dominica)

*celestina [azul, blanca]* ([blue, white] heavenly, Cuba)

*herbe a bouc [a femme, à la vierge, à pisser, aux sorciers]* (billy goat [woman's, Virgin's, urination, sorcerer's] herb, Dominique, Martinique)

*mastruço* (from Latin *masturtiu*, the crucifer; comparison obtuse, Brazil); *mondastro [mentastro]* (Puerto Rico)

*petit pain doux* (little sweet bread, Dominica, Dominique, Martinique)

*rompezaragüey* (shoe breaker, same name given to *Vernonia menthaefolia*, Dominican Republic)

*yerba de cabro [cabrio, chivo]* (goat herb, Puerto Rico, Dominican Republic)

*zeb a fam* (woman's herb, French Antilles)

Because of extensive parallelism and convergence, generic definition in the Asteraceae has long been problematical. Linnaeus put this species in *Eupatorium* in 1753, as had

Plukenet, Dillenius, and Gronovius before him. De Candolle put it in *Conoclinium* by in 1836, and even then, some did not accept the disposition. However, as now understood, *Conoclinium* is a genus of three species endemic to the eastern United States and nearby Mexico (Mabberley 1997). Like many plants in *Eupatorium*, this one has a long history of medicinal use.

*Bouton blanc* is used in Dominica as a tea for colds or simply as a cooling tea (Honychurch 1987). Formerly the herb was widely used as a diuretic, against coughs and colds and dysmenorrhea, to induce abortion, and as a bath for skin eruptions (Roig 1945, Ayensu 1981, Honychurch 1987). Plants contain alkaloids, cyanogenic glycosides, and volatile oils such as eugenol, coumarin, and decoumarol (Ayensu 1981).

### *Conopholis*

(From Greek *conos*, cone, and *pholis*, scale, a reference to the bracts on the flower and fruit clusters making them resemble pine-cones)

***Conopholis americana*.** From Britton and Brown 1898.

#### *Conopholis americana* (of America)

cancer-root (by 1546, there were references to herbs called “cancer” or “herbe cancer”; John Gerarde’s *Herball* of 1597 mentioned “cancer-wort,” which apparently referred to *Linaria* or *Veronica*; however, “cancer-root” in association with plants seems to have appeared in 1714, and was clearly associated with this species by 1856)

squaw-root [squawroot] (apparently first published in association with “a medicinal plant put up by the Shakers,” in 1848. By 1856, Asa Gray’s *Manual of Botany* identified both “squawroot” and “cancer-root” with *C. americana*)

These plants belong to the family Orobanchaceae, partly defined because many members are saprophytic or parasitic. *Conopholis americana* grows on the roots of trees, much like

its relatives *Epiphagus* and *Orobanche*. There are only two species of *Conopholis*, and both grow in the southeastern United States.

Although Europeans had never seen *Conopholis* when they arrived in the New World, they were familiar with *Orobanche* (which see), as there are 45 species in Europe (Mabberley 1997). In fact, Linnaeus first named the Florida species in 1767 and called it *O. americana*. It was not until 1825 when Carl Friedrich Wilhelm Wallroth (1792–1857) created *Conopholis americana*. Some 19 years later, F.M.Liebmann described the second species, *C. alpina*, from Puebla, Mexico. Now, *Conopholis alpina* (= *C. mexicana*, = *C. alpina* var. *mexicana*) is known to grow from Texas, New Mexico, Arizona, and Mexico south to Panama (Correll and Johnston 1970, Mabberley 1997).

Although no records have been found of *C. americana* being used by indigenous people, there are records that *C. alpina* was used. Moerman (1998) recorded that the Keres near Albuquerque, New Mexico, used it to strengthen weakened tuberculosis patients. Their relatives in the same area, the Jemez, used it in magic to make runners faster.

Both Hocking (1997) and Mabberley (1997) note that *C. americana* is medicinal, and that it has been used as an astringent. The common name “squawroot” perhaps indicates that the settlers learned the use of these herbs from women in eastern tribes. As the Shakers are known to have learned much of their herbal lore from local tribes, that interpretation becomes more likely. Whether or not the name “cancer-root” suggests use in treating malignant sores is uncertain.

### *Conyza*

(Latin *conyza*, and Greek *konyza*, a flea, a name originally used by Aristotle, 372–287 B.C., Nicaner, Theophrastus, 372–287 B.C., and Dioscorides, fl. A.D. 40–80, for two kinds of European composites; Christian Freidrich Lessing, 1809–1862, reapplied the name to these plants)

***Conyza canadense*.** a. Habit, b. Flower head, c. Disk flower, d. Achenes.  
*Drawn by Regina O. Hughes. From Reed 1971.*

***Conyza canadense*** (from Canada) (= *Erigeron canadensis*)  
*atakló:lásti* [atakro:lásti] (*takli*, bush, *lvste*, black, Creek); *taklô:ci* [takrô:ci]  
 (black bush, Mikasuki); *vtaklv lvste* [vtakrv lvste] (*vtaklv*, plant, *lvste*, black, Muskogee)  
*atsil-sun'ti* (fire-making material; *ajila*, fire, Cherokee)  
 bitterweed (New Mexico); butterweed (corruption of “bitterweed”?, USA)  
*canhlo'gan was'te'mna iye'cece* (resembling sweet-smelling herb [*Ambrosia*, which see], Lakota)  
 colt's tail (New Mexico); horsetail (USA); [smooth] horseweed (USA)  
 fleabane (repels fleas, New Mexico)  
 fox tail (Dutch Antilles)  
*gababi'kwuna'tig* (knotted tree, Ojibwa)  
*ha mo u'teawe* (leaf ball flowers, Zuni)  
*hierba de burro* (donkey herb, Sinaloa)  
*no'sowini* (sweat, because it is used in the sweat bath, Meskwaki)  
*pazotillo* (little skunk feces or little *Chenopodium ambrosioides*?, from Náhuatl *epatl*, skunk, *tzotl*, filth, New Mexico)  
 pride weed (New Mexico)

German physician Lessing created the genus *Conyza* in his *Synopsis Generum Compositarum* (Synopsis of Genera of Compositae) published in 1832. Most people continued putting this species in *Erigeron* until Arthur J. Cronquist (1910–1992), an influential student of the family Asteraceae who worked at New York Botanical Garden, insisted that it was distinct in 1943. Now the genus contains about 60 species that grow in temperate and warm regions around the world. Europe had no native species, but this one and another are naturalized there (Mabberley 1997).

People throughout the range of the species use it for medicine to treat a variety of ailments (King 1984, Kindscher 1992, Vásquez and Jácome 1997, Moerman 1998). Curtin (1947) recorded a number of uses for the herbs in New Mexico. The Seminoles told Sturtevant (1955) they used the plant to treat coughs and colds. They also told Bennett (1997) that it was still in use but would not explain the application. The Houma used it to treat leukorrhea (Speck 1941).

### *Corallorhiza*

(From Greek *corallion*, coral, and *rhiza*, root; the name was applied to these orchids in 1755 by Abraham Gagnebin, 1707–1800)

***Corallorhiza odontorhiza*.** From Britton and Brown 1896.

coral-root (translated from the Greek name, apparently not in English until ca. 1845)

*freumh corail* (coral root, Gaelic)

*Korallenwurz* (coral root, German); *korallrot* (coral root, Norwegian)

*racine de corail* (coral root, French)

***Corallorhiza odontorhiza*** (toothed-root, from their shape)

chicken-toes

[autumn, late] coral-root [coralroot]

crawley root  
 dragon's claw [dragon-claw] (used for the orchid by 1832)  
 fever-root (in use by 1884 for the root-parasitic *Pterospora andromeda*, Ericaceae, and for *Triosteum perfoliatum*, Caprifoliaceae; use for *Corallorhiza* is either a confusion or comparison with *Pterospora*);  
 dever-root [deverroot] (a corruption of "fever-root"?)  
 turkey claw

Willdenow named these terrestrial orchids *Cymbidium odontorhiza* in 1805. Shortly afterward, French botanist Jean Louis Marie Poiret (1755–1834) moved the species to *Corallorhiza*. Currently, the genus contains 15 species that grow in northern temperate regions around the world. One species is native to Europe (Mabberley 1997).

These orchids have no chlorophyll (Mabberley 1997). Instead, they rely on their relationship with the fungi on their roots for survival (mycotrophs). The plants are typically a reddish color, sometimes marked with darker blotches.

No records have been found of indigenous people using *C. odontorhiza*, but farther north and west *C. maculata* was used by the Iroquois, Navajo, Paiute, and Shoshone (Correll 1950, Moerman 1998). Correll (1950) speculated that it was used to make a tea to build up blood because of its red coloration.

Other indigenous uses of *C. maculata* are as a diaphoretic, febrifuge, and sedative. Those are the same as for non-indigenous application of *C. corallorhiza*, and it seems likely that both species were used similarly. Ellingwood and Lloyd (1898) and Felter (1922), prominent Eclectic physicians in their time, used the Florida species as a diaphoretic, for fever, and as a sedative. Ellingwood and Lloyd (1898) considered it a diaphoretic *par excellence*.

These are endangered plants in Florida (Coile 2000). Because of their special habitat requirements, they seem to be declining throughout their range.

### **Cordia: Blood-berries and Dog Tits**

(Named by Linnaeus in honor of the German botanist and pharmacist Valerius Cordus, 1514?–1544, one of the fathers of pharmacognosy)

In the early 1970s, blood-berry (*Cordia globosa*) was one of the rarest shrubs in the pinelands of Miami-Dade and Monroe Counties. Then, the butter

***Cordia*.** *Cordia globosa* , a. Flowering branch, b. Flower bud. c. Flower from above, d. Flower, side view. e. Flower longitudinally dissected, f. Pistil. g. Floral diagram, h. Fruit in cluster on left, enlarged fruit on right. *Cordia sebestena* , a. Flowering branch, b. Details of base of inflorescence , arrow showing sympodial renewal shoot from leaf axil. c. Leaf with details of lower and upper surfaces (right); inset is of *C. globosa* for comparison of size. d. Long-stamened flower, longitudinally dissected, with detail of throat , e. Short-stamened flower, with detail of throat , f. Flora diagram, g. Fruits, h. Fruit in longitudinal section and transverse section . Both drawn by Priscilla Fawcett. From Correll and Correll 1982.

fly enthusiasts discovered the plants and *C. globosa* appeared everywhere in cultivation. These devotees may well have invented the name blood-berry, because it is not in any of the older literature. The same people, or their horticultural friends, surely created the more recent name, butterfly sage.

Blood-berry is perhaps based on *yerba de la sangre* (blood herb, Cuba) or maybe *sanguinaria* (for the blood, Cuba). The red fruits following the small clusters of white flowers make the names seem appropriate. However, the Spanish versions were based on medical uses. In Cuba and Hispaniola, a decoction of the plants is highly esteemed as an astringent and hemostat in instances of pulmonary hemorrhage. Throughout the range of the species, the main application is for lung problems (Roig 1945, Liogier 1974, Morton 1981). That use holds through the range of *C. globosa* in southern Florida, the Bahamas, Cuba, Hispaniola, and Puerto Rico to Aruba, Bonaire, Curaçao, and Margarita, thence onto mainland Venezuela, Colombia, and in Central America through Belize, Guatemala, El Salvador, Honduras, Nicaragua, Costa Rica, and north to Mexico (Yucatán, Chiapas, Campeche, Morelos, Quintana Roo). Jamaicans use a tea to treat colds and tightness of the chest. In the Grenadines the plant is used as a remedy for colds, chest congestion, and for menstrual cramps (Morton 1981).

The name butterfly sage is also related to black sage (Caymans, Jamaica), man black sage (Jamaica), and wild sage. Those are simply English variants of the Spanish *salvilla cimarrona* [*savilla cimarrona*] (wild sage). People everywhere have learned that *Salvia* (Lamiaceae) is a useful medicine, and any plant that resembles it may have “sage” applied. People use the name sage because the leaves of the blood-berry are somewhat fragrant.

Many of the other common names make more or less obvious reference to medical applications. Several plants in the French Antilles are called *bonbon* (candy), with different modifiers, and some are medicinal. *Cordia globosa* is *bonbon rond* (round candy, Guadeloupe, Martinique). The Jamaican gout tea may be a valid name (and use), or it may be a misunderstanding of the French *guérit-tout* (cure all, Guadeloupe, Martinique, Trinidad). Several Carib bean medicinal plants are named after people, perhaps because they were renowned healers. For blood-berry, it is John Charles [John Charley] (Jamaica) or *Juan prieto* (black John, Dominican Republic).

There may be more than one message in *rompe camisa hembra* (female torn shirt, Cuba). That is especially true since the antonym is *rompe camisa macho* (*Turnera diffusa*). *Turnera*, known in the herbal industry as *damiana*, is touted as an aphrodisiac. Maybe *C. globosa* is also used that way.

Several other names are probably allusions to herbal medicines. Comparison with the avocado (*Persea americana*) with the name *aguacatico* (little avocado, Venezuela) surely denotes medicinal use. Some names comparing the shrubs with Verbenaceae include *caraiquito negro* (black *Lantana*, Venezuela) and *cariaquito de sabana* (savanna *Lantana*, Venezuela). Maybe the inclusion of indigenous words *saraguaso prieto* (black *saraguaso*, maybe Taino, Puerto Rico) complicates this imperfectly known name. No translation has been found for *ateje* (Taino?, Cuba), but it is used for more than one *Cordia*.

Both *copillo* (little cup, Puerto Rico) and Curaçao bush (British Antilles) allude to medicines. However, it is not clear what is meant by *cuajatina* (coagulates ink [or coffee], El Salvador), unless it is an allusion to a terrible taste. Other names with obtuse allusions are *herbe à boue* (filth herb, Guadeloupe, Martinique), *muñeco* (doll, Dominican Republic), *palo negro* (black stick [tree]), and *papita* (little potato, Cuba).

A decoction of blood-berry with fever grass (*Andropogon citratus*) and bamboo (*Bambusa vulgaris*) is used against fever (Ayensu 1981). A simple decoction of blood-

berry has been used in Cuba and elsewhere as a depurative for troublesome skin eruptions (Roig 1945). This mixture is used internally and in baths. In Jamaica the plant decoction is used as a beverage. People in Yucatán employ the leaves as seasoning in cooking armadillo (*Dasypus novemcinctus*) to improve its flavor.

It is hard to see how *mierda de gallina* (chicken feces, Cuba) or *zompopo* (simpleton or a species of ant, El Salvador) might indicate any human use, but perhaps they do. *Cenigal* (*ceniza*, ash, with the suffix *-al*, an ash-colored thicket, Dominican Republic) may also suggest a use or simply be descriptive. The names *diente de chucho* (dog's tooth) and *diente de perro* (dog's tooth) surely refer to the distinctive leaves. In Maya, the name is simply a mention of a pest, *hauche* (*hau* [haw], open the road, *che'*, tree, Maya). This name is given because the trees grow frequently in paths and need to be removed.

No further information was found on *achechive* [*achechibe*]; it seems to be an indigenous name. I would not be surprised if the name had not been derived from *anacahuite*, a Mexican name originally given to *C. boissieri* and then to *C. sebestena*.

*Cordia globosa* is not unique among species in the genus in having people use it. Linnaeus put three species in *Cordia* in 1753, and two of them had reputations as medicines. The one best known in Europe was the Old World *C. myxa* (Grigson 1986), which Linnaeus had grown at the botanical garden in Uppsala. He had previously reported on it in his book *Materia Medica* in 1749.

A first-hand report of American species was made by Hans Sloane from the time he spent in Jamaica. Although Linnaeus visited Sloane in Chelsea in 1736, he was dismayed that the herbarium was bound up in books and could not easily be studied. The names Linnaeus created based on Sloane came from his publications and not from the herbarium.

Because of the difficulty and time needed to browse through the 265 volumes of Sloane's specimens, perhaps it is understandable that Linnaeus did not mention what is now called *C. globosa* being among them. On the other hand, perhaps he did not know what to do with it. In those cases, he simply kept quiet.

Sloane's illustration of *Caryophyllus spurius inodorus*, *folio subrotundo scabro* (false odorless carnation, with almost round scabrous leaves) served as the basis for what Linnaeus called *C. sebestena*. We have to wonder if Linnaeus knew the meaning of the Arabic name *sebestena* (from *seg piston*, dog tits, Grigson 1986), but I would bet he did.

The other reference Linnaeus used for *C. sebestena* was Mark Catesby. In his text, Catesby (1734–1747) reported that the wood of that tree “contains much Gum, in Smell and Appearance resembling Aloes, and is by the Inhabitants of the Bahama Islands (where it grows) called *Lignum Aloes*.” Even today, aloe-wood remains a common name for the species in the Bahamas.

Because of the tree's similarity to the Mexican species *C. boissieri* it is known by the Náhuatl name for that species, *anacahuite* [*anacahuitta*, *anacagüita*, *anaconda*] (paper-tree, Yucatan, Cuba, Puerto Rico). The Maya of Yucatan call it *kopte* [*copté*, *sak-k'opté*, *zak-k'opté*, *zac-copté*] (*sak*, white, *kopte'*, with a hard center). The Spanish *siricote* [*ciricote*, *ziricote*] (Yucatán, Guatemala, Belize) or *siricote blanco* (white *ciricote*, Yucatán) is surely a corruption of the Mayan. These names are used for the tree whose wood is hard, and whose fruits are used for food (Rico-G. et al. 1990). Fruits are made into preserves or jam, and they have a good flavor. The fresh fruits directly from the tree

are considered edible, but the taste is not good. Apparently, sweetening and preserving fruits improve the taste.

Cubans call it *vomitel* (vomit) or *vomitel amarillo* (yellow vomit), and use it for stomach problems (Roig 1945). In the Lesser Antilles *C. sebestena* is called *bois râpe* (rough tree, because of the sandpapery leaf surface, Guadeloupe, Martinique), *manhage* (Aruba, Bonaire, Curaçao), scarlet *accordia* (Dutch Antilles), scarlet flower (Dutch Antilles), *sébastienier* (Guadeloupe, Martinique), and *ti-soleil* (little sun, French Antilles). It is also called *caujaro Español* [*cawara spaño*, *karawaara spanjool*] (Spanish *caujaro*, Aruba, Bonaire, Curaçao). *Cordia alba* in Venezuela was the original *caujaro*, perhaps a name of Arawakan language origin.

*Cordia sebestena* is also in Florida, but it is questionable that it is native. The legend says that John James Audubon gave it the name “Geiger tree” because of the specimens that 19th-century ship captain John Geiger planted at Key West (Little 1979). According to Acevedo-Rodriguez (1996), the species is only native to the Greater Antilles, the Bahamas, and the Virgin Islands. He considers it introduced elsewhere as an ornamental. Indeed, it has been cultivated widely through the Americas and elsewhere for its orange-red flowers and white fruits. Some of the plants may also have been grown for their edible fruits and medicinal traits. Certainly, the species has a venerable reputation for both.

While no chemical studies seem to have been made on either of these Florida plants, several other members of *Cordia* have been examined. There are multiple biologically active compounds in those species, including arabinoglucan, essential oils, terpenes, meroterpenoid naphthoquinones, and taxifolin (Srivastava and Srivastava 1979, Velde et al. 1982, Basu et al. 1986, Bieber et al. 1990, 1994, Fun et al. 1990, Nakamura et al. 1997). Other studies have shown these and other *Cordia* extracts to be antifungal, anti-inflammatory, antiulcer, antiviral, hepatotoxic, and larvicidal (Tiwari and Srivastava 1979, Marston et al. 1988, Hayashi et al. 1990, Sertie et al. 1990a,b, Rapisarda et al. 1993, Akhtar and Ahmed 1995, Ioset et al. 1998).

A Lesser Antillean name summarizes the utility of *Cordia* although it refers directly to *C. sebestena*. *Mapou rouge* (red *mapou*, Guadeloupe, Martinique), contains a Cariban element (*mápuia*, bush-spirit, Hodge and Taylor 1957). Maybe the *Cordia* species house the essence of the healing force.

### *Coreopsis*

(From Greek *koris*, a bug, and *opsis*, resembling, an allusion to the seeds)

*Coreopsis leavenworthii* (honors M.C. Leavenworth, 1796–1862, a student of southern U.S. botany)  
tick seed (southeastern USA)

***Coreopsis leavenworthii*.** Drawn by  
P.N.Honychurch.

Linnaeus was familiar with eight species of *Coreopsis* when he described the genus in 1753. All but one of those he knew was from North America. Later it was found that the genus is endemic to the Americas, and now it contains 50 species (Mabberley 1997). Several have been used in medicines.

The Seminoles used an infusion of *C. leavenworthii* to treat heat prostration (Small 1933). However, Sturtevant (1955), Bennett (1997), and Snow and Stans (2001) have not subsequently found the Seminoles using it.

### *Cornus*

(The Latin name of the cornelian cherry, *Cornus mas*, from Greek *keras*, and Latin *cornum*, horn; akin to Akkadian *qarnu*, and Hebrew *qeren*)

*chàpacor* (Carolina Algonquians); *vtchappoc* (Powhatan, Virginia) (both forms were interpreted by Geary 1955 as a *Cornus* whose roots were used to make a red dye)

*còrn* (Gaelic); *cornel* (from Latin *cornum*, horn, perhaps from the color; akin to Greek *kerasos*, cherry; first applied in the 1550s by William Turner and other herbalists); *cornouiller* (cornel tree, although originally referring to the fruit, French; related German names are *Cornellbaum*, cornel tree, and *Kornel-berre*, cornel berry)

dogwood (derived from “dog-tree,” which in turn was taken from “dog-berries,” also called

**Cornus.** *Cornus alternifolia* . From Sargent 1905. *Cornus amomum* . From Britton and Brown 1897. *Cornus asperifolia* . From Sargent 1905. *Cornus florida* . From Sargent 1905.

hound's tree or hound's berry, from at least 1550 and Turner's *Herbal*; the leaves were incorrectly considered a cure for hydrophobia)

*hakchupilhko* [*hakchipilhko*, *akchupilhko*, *hakchupilhkaš*] (*hakchuma*, tobacco, *pilhko*=?, Choctaw)

*Harriegel* (heart rail, German)

*ka-na'-si-ta'* (Cherokee)

*nan'taxpa'yudi* (Biloxi)

*shen-don-shu-gah* (bitter red berry, Osage)

*vtvphv* [*atvp'ha*, *atapha*] (Creek, Muskogee); *cofi* (Hitichiti)

***Cornus alternifolia*** (alternate leaved)

alternate-leaved dogwood [alternateleaf dogwood, alternate-leaf dogwood]

[blue, purple] dogwood

green osier [green-osier] ("osier" from Latin *ausaria* or *osaria*, willow-bed, because the word was originally restricted to willows, *Salix*)

*gwai-gee-àp-aip* (Kiowa)

*mowo'samic* (moose wood, Potawatomi); *muj'omij'* (moose plant, Ojibwa)

pagoda [dogwood]; pagoda-cornel

pigeonberry

umbrella-tree

*zaikh-'koñ-a* [*sek'a'n*, *sai'kañ*] (arrow wood, Kiowa)

***Cornus amomum*** (a Latin name of some shrub)

*chan-shasha* (*chan*, wood, *shasha*, red, Dakota); *ruhi-shutsh* (*shutsh*, red, Winnebago)

*kinnikinnick* [*killegenico*, *killickinnick*, *kinnakinnec*] (mixture, Algonquin)

*ninigahi* (*nini*, pipe, *igahi*, to mix, because it was mixed with tobacco for the pipe, Omaha-Ponca)

*rapahat* (*ra*, stick, *pahat*, red, Pawnee)

red dogwood; red willow

silky cornel; silky dogwood

***Cornus asperifolia*** (rough-leaved)

*mansa-hte-hi* (*mansa*, arrow, *hte*, real, *hi*, plant, or “real arrow tree,” Omaha-Ponca); *mansi-hotsh* (Winnebago); *mon'-ça hi* (arrow shaft stalk, Osage)

*nakipistatu* (*nahaapi*, tree, *kipis*, arrow, *tatu*, real, Pawnee)

rough [rough-leaved, tough-leaved, toughleaf] dog-wood

***Cornus florida*** (flowering)

American box; [New England] boxwood; cornel box; dog box; false box [false boxwood]

[Indian] arrow-wood; *bois fleche* (arrow-wood, French)

*blomsterkornell* (flowering cornel, Dutch); [flowering, white] cornel;

Cornelian-wood; corneliustree; *corniolo americano* (American cornel, Italian); *cornouiller de la floride* (Florida cornel, Quebec)

*cornus americano* (American dogwood, Spanish)

country-timber

[common white, eastern flowering, Florida, flowering] dogwood; *bois de chein* (dogwood, French)

*hattawanominschi* [*hat-ta-wa-no-min-schi*] (*minschi*, plant, Delaware); *monhacaniminschi* [*mon-hacan-ni-min-schi*] (*moon-hak-an*, digging stick, *hee*, thing indicated, *minschi*, plant, Delaware)

*kanunsi'ta* (Cherokee)

*nahiskilá* (Koasati); *naskila* (Alabama)

nature's mistake (some think the bracts are aberrant petals)

red [osier, willow]

*tá'si yapare* (dog tree/wood, Catawba)

***Cornus foemina*** (female; so considered by Philip Miller, 1691–1771, as opposed to the “male,” *C. florida*)

[blue-fruit, stiff cornel, stiff, swamp] dogwood stiff-cornel [stiffcornel]

Europe has four native species of *Cornus*, although Linnaeus ([1753] 1957) included only three of them; the other two he described were American *C. canadensis* and *C. florida*. There are now about 65 species, most of them in the north temperate zones (Mabberley 1997). The common names in diverse European and American languages give some indication of how important the genus has been to people.

Two widespread uses of branches and leaves of *Cornus* were for making arrows and in smoking. At least the Comanche, Omaha, Pawnee, Ponca, and Winnebago used *C. asperifolia* stems to make arrow shafts (Gilmore 1919, Moerman 1998). The Comanche also used *C. florida* branches for arrows (Tull 1999). One of the widespread names for

*Cornus*, especially *C. amomum*, was *kinnikinnick*. That designation was used for several plants, but often implied that they were smoked alone or added to tobacco. The Lakota, Menomini, Omaha, Pawnee, Ponca, and Winnebago added dried *Cornus* inner bark to tobacco (Gilmore 1919). The Micmac used dried *C. foemina* bark to mix with their tobacco (Moerman 1998). Probably among all these people, but at least with the Winnebago, *Cornus* was used as a ceremonial smoke (Moerman 1998).

The Cherokee used *C. alternifolia* wood for carvings and loom shuttles; the Ojibwa used the wood for awl handles, mauls, and war clubs, and the twigs for thatch and other materials (Moerman 1998). The Anglos used the wood for small articles, tool handles, wheel hubs, and pulleys (Vines 1977). Kalm ([1753–1761] 1972) added that settlers made weaver's spools, joiner's planes, and wedges. Unspecified tribes used the roots to make a dye (Vines 1977). The dye probably was like that made from *C. florida*, either rusty brown or bright yellow, depending on the mordant. Tull (1999) added that numerous tribes used several *Cornus* species to color baskets and porcupine quills.

Documentation was found for only two groups of Muskogean people using dogwood. The Houma made a decoction of *C. florida* and *C. foemina* roots or bark to alleviate fever, including malaria (Speck 1941). The Alabamas used the bark of *C. florida* to relieve diarrhea (Swanton 1928a). However, the Creek name *vtvphv* [*atapha*] and the Mikasuki name *atopa:bi* (dogwood replica; see *Psychotria*: Wild Coffee) suggest a wider application among Muskogean people. Considering the wide use of *Cornus* by indigenous groups and subsequent immigrants, it seems likely that all species were used by everyone who lived near them.

The tannins in *Cornus* are well known, and are at least some of the active compounds involved in their use as remedies (Yazaki and Okuda 1989, Hatano et al. 1990, Wedge et al. 1995). Felter (1922) recorded that *C. florida* contained 3% tannin, presumably in the bark. He also noted that it contained a bitter chemical called cornine [cornin]. Millspaugh (1892) was of the opinion that the bitter compound was an alkaloid; however, a more recent study did not find alkaloids in *C. florida* (Barbosa et al. 1990). Instead, cornin is an iridoid glycoside, and it seems to occur in many species of *Cornus* (Stermitz 1998, Tanaka et al. 2001).

Old World species are also known to contain medically active glycosides (Hatano et al. 1990). *Cornus officinalis* includes triterpenoids, ursolic acid, saponins, cornin, morroniside, loganin, and sweroside (Hsu 1986). As Millspaugh (1892) reported several of those compounds for *C. florida*, it would appear that there is a shared variety of chemicals in *Cornus*.

The tannins at least would explain the widespread use for skin problems and piles. The Cherokee, Iroquois, Menomini, and Winnebago used *C. alternifolia* and *C. amomum* to treat skin problems (blisters, cancer, navel, ulcers, venereal sores) (Hamel and Chiltoskey 1975, Moerman 1998). At least the Menomini used a bark infusion of *C. alternifolia* to treat piles (Moerman 1998). The Cherokee also employed a bark infusion of *C. alternifolia* and *C. florida* for measles (Hamel and Chiltoskey 1975).

One of the prime applications of *Cornus* was to treat chills, coughs, laryngitis, and fever associated with colds and flu. For this purpose decoctions or infusions of stems, bark, or roots from *C. alternifolia*, *C. florida*, and *C. foemina*, were used by the Cherokee, Ojibwa, Iroquois, and Potawatomi (Smith 1933, Hamel and Chiltoskey 1975,

Moerman 1998). The Iroquois also prescribed a bark infusion of *C. amomum* for chest congestion and one of *C. alternifolia* for tuberculosis (Moerman 1998).

The Cherokee treated colic with both a root bark and flower infusion of either *C. alternifolia* or *C. florida* (Hamel and Chiltoskey 1975). The Iroquois and Winnebago made a remedy for indigestion with an infusion of the inner bark of *C. amomum* (Moerman 1998). The Cherokee, Menomini, Rappahannock, Winnebago (Hamel and Chiltoskey 1975, Moerman 1998) treated diarrhea with an infusion of root bark from *C. alternifolia*, *C. amomum*, or *C. florida*. Worms, especially in children, were expelled with a bark infusion of either *C. alternifolia* or *C. florida* by the Cherokee (Hamel and Chiltoskey 1975). The Iroquois used bark infusions made from either *C. alternifolia* or *C. amomum* (Moerman 1998) internally for urinary problems and venereal disease.

*Cornus* was considered both emetic and laxative. A bark infusion of either *C. alternifolia* or *C. amomum* was used by Iroquois and Ojibwa as an emetic, and an infusion of *C. amomum* was used as a laxative by the Iroquois (Moerman 1998). Root bark infusions or decoctions of *C. alternifolia* and *C. florida* were considered stimulant by the Cherokee (Hamel and Chiltoskey 1975); the Delaware and Rappahannock considered *C. florida* a tonic (Moerman 1998).

People from the Iroquois of New England to the Cherokee of the Carolinas considered *Cornus* analgesic. The Iroquois applied a bark infusion of *C. alternifolia* to swollen areas (Moerman 1998). The Cherokee used a bark infusion of *C. alternifolia* and *C. florida* to treat headache and women's backache (Hamel and Chiltoskey 1975). The Iroquois used a bark infusion of *C. amomum* as a bath to help babies sleep (Moerman 1998). Tannins and some of the other compounds in *Cornus* are known to be antibacterial, which would explain why the Cherokee, Ojibwa, Iroquois, and Potawatomi used a root bark infusion of *C. alternifolia* and *C. florida* to treat sore eyes (Smith 1933, Hamel and Chiltoskey 1975, Moerman 1998).

There was a widespread belief among indigenous people that the blood could become "tainted" and thus cause sickness. That belief persists in some people in the United States and among many Bahamians today. The Cherokee and Rappahannock believed a root bark infusion of *C. alternifolia* and *C. florida* improved the blood, and thus made a sick person well (Hamel and Chiltoskey 1975, Moerman 1998). Perhaps the Iroquois were also aware that goiter was caused by a diet deficiency, although they surely did not know it was iodine. In any event, they took a bark infusion of *C. amomum* for that malady (Moerman 1998).

Fruits of *C. florida* are typically considered somewhat poisonous, although they have been soaked in brandy as a "bitter digestive tonic and for acid stomach" (Foster and Duke 1990). Rafinesque said the people in Louisiana ate *C. amomum* fruits (Hedrick 1919).

A widespread historical application for *Cornus* stems was to make "chew sticks" for cleaning the teeth (Millspaugh 1892, Uphof 1968, Coon 1974, Lewis and Elvin-Lewis 1977). This practice was unknown among indigenous people although they used other materials to clean their teeth (Lewis and Elvin-Lewis 1977). The fact that they adopted use of dogwood stems to clean their teeth from the black slaves confirms they were close observers (Coon 1974). Both *C. amomum* and *C. florida* were preferred, but all were likely used. Coon (1974) noted "the astringent properties of the bark being valuable for hardening the gums." Millspaugh (1892) and Lewis and Elvin-Lewis (1977) similarly comment how effective *C. florida* stems were in removing plaque, leaving the gums pink

and firm, and the teeth white and decay-free. However, Foster and Duke (1990) warn that the hard fibers tend to erode the teeth much as a hard-bristle toothbrush does.

An important ethnobotanical aspect of *C. florida* that is often overlooked was to keep track of seasons. Several groups planted corn when the dogwood bloomed because that was considered a sure sign that winter was over (Millsbaugh 1892, Coon 1974).

### *Crataegus*

(From Greek *krataigos*, an ancient name for a kind of flowering thorn used by Theophrastus, 372–287 B.C.; composed of *kratus*, strong, *akakia*, *akis*, thorn)

***Crataegus*.** *Crataegus aestivalis* .

From Sargent 1905. *Crataegus*

*crusgalli* . From Sargent 1905.

*Crataegus flava* . From Britton and

Brown 1897. *Crataegus spathulata* .

From Sargent 1905.

*a'ho* (Ofo)

*aubépine* (from popular Latin *spina alba* of Pliny, A.D. 23–79; coexisted as *aubepin*, masculine form, because *spinus* is shrub, while *spina* is spine, French); *biancospino* (white thorn, Italian); *epine blanche* (white spine, France); *Weissdorn* (white thorn, German); *wittedoorn* (white thorn, Dutch)

*cenellier* (Quebec)

*chanafila* [*shanafila*] (black haw, Choctaw); *selvuv* [*cate*] ([red] haw, Muskogee)

[red] haw [hawthorn] (from Old English *haga*, hedge; akin to Dutch *haag*, German *Hage*, Danish *have*, garden; see *Celtis*: Hackberry for more on etymology)

*machkigen* [*machkigenamúnschi*] (*kiminschi*, plant, Delaware); *mine'saga'wunj* (having fruit and spines, Ojibwa)

*oki'neyak* (Plains Cree)  
*pommettes* (little apples, Quebec)  
*ta-çpon'* (Osage)  
*tschigachrèchtes* (Onondaga)  
*uath* (Gaelic)

***Crataegus aestivalis*** (summer-flowering)

*a'stantka'* (Biloxi)  
*chommilámhi* [*chommilámmi*] (*chommi*, anus, *lomhi*, hidden; the name refers to the dimple on one end of the fruit, Alabama)  
 [apple, May, May hawthorn] haw

***Crataegus crusgalli*** (spur of a cock)

*squimenuckee* (Shawnee, fide Edgar 1891)  
 [cockspur, pin]-thorn [hawthorn]; thorn-[apple, bush]

***Crataegus flava*** (yellow)

summer haw (used by Williams [1837] 1962); yellowleaf hawthorn

***Crataegus marshallii*** (named for dendrologist Humphrey Marshall, 1722–1801, who first described it)

*cittihómma cobácobá* (*chi*, you, *ititi* eye, *hommá*, red, *cobá*, big, Koasati)  
 parsley hawthorn (superficially, the leaves resemble those of parsley, *Petroselinum crispum*)

***Crataegus spathulata*** (wedge-shaped, referring to the leaves)

*chittihámma* [*chittiomma*, *chittihomma*, *chittihomma sawwa*] (*chi*-, you, *ititi* eye, *homma*, red, *sawwa*, small, Alabama); *cittihómma* [*tithómma*] (*cíl*, you, *ititi* eye, *hommá*, red, Koasati)  
 little-hip hawthorn [littlehip hawthorn]; [pasture, small-fruit] hawthorn  
 spathulate haw (a book name); summer haw (used by Williams [1837] 1962)

***Crataegus uniflora*** (one-flowered)

dwarf hawthorn; winter haw (used by Williams [1837] 1962)

Fernald (1950) recognized 103 species of *Crataegus* in the northeastern United States. Many people believe that there are fewer species than that. To illustrate the chaotic condition of the taxonomy of the genus, a story made the rounds when I was in graduate school at Washington University in St. Louis, Missouri, in the late 1960s. The prevalent expert on *Crataegus* was suspected of naming every minor variant as a new species. So, a cunning colleague went into the field, made multiple collections from a single tree, and gave them all fictional numbers and localities. These samples were then sent to the expert for identification. Specimens from the single tree were returned with more than a dozen species names. Mabberley (1997), who usually puts numbers of species with no comment, wrote for *Crataegus* that there were 186, plus maybe 78, species.

Europeans and indigenous Americans are known for eating the fruits of hawthorns—particularly when there is nothing better available. There are records of fruits having been eaten from *C. aestivalis*, *C. crusgalli*, *C. flava*, *C. marshallii*, *C. spathulata*, and *C. uniflora* (Yanovsky 1936, Hocking 1997). Moerman (1998) lists 12 other species whose fruits were eaten across North America.

The wood from all *Crataegus* is hard and heavy, and it was used by Europeans and Americans. Harrar and Harrar (1946) say that the famous Irish shillelaghs (cudgels) were made from the wood of black hawthorn. In the Americas, at least the wood of *C. crusgalli* has been used for tool handles (Uphof 1968).

The Cherokee considered an infusion of the bark of *C. spathulata* good for the circulation and to prevent spasms. Berries were eaten to improve the appetite, particularly when ill (Hamel and Chiltoskey 1975). They also drank a bark tea or bathed in it to “ward off tacklers” during ballgames (Hamel and Chiltoskey 1975).

There are three other *Crataegus* in Florida that surely were used. Foster and Duke (1990) consider all the species in the genus and comment that *Crataegus* is a famous herbal heart tonic used throughout the world. For example, Culpeper (1653) wrote: “The seeds in the berries beaten to powder being drunk in wine, are good against stone and dropsy.” Lewis and Elvin-Lewis (1977), Foster and Duke (1990), Swerdlow (2000), and Duke et al. (2002) record that modern research has confirmed its use for hypertension, weak heart, angina pectoralis, and arteriosclerosis.

Some of the other uses for species in Florida are in other medicines. Roots of *C. crusgalli* were aperatives, deobstructants, and diuretics in Mexico (Hocking 1997). *Crataegus marshallii* is considered a substitute for *C. oxyacantha* as a hypotensive (Hocking 1997). Unripe fruits of *C. uniflora* were used as an astringent in bladder disorders and as a cardiotonic among the Meskwaki (Vogel 1970, Hocking 1997).

### *Crinum*

(From Greek *krinon*, a lily; Pliny, A.D. 23–79, used the name *crinon* for the red lily and Linnaeus reapplied it to the American plants)

#### *Crinum americanum* (from America)

*halpatcolasi* [*halpattcolaçi*] (alligator tongue, Mikasuki)

*lirio de San Pedro* (Saint Peter’s lily, Cuba)

[Florida, southern] swamp lily

Linnaeus ([1753] 1957) knew four species of *Crinum* when he created the genus, one from the Americas, two from India, and the fourth from Africa. *Crinum americanum* he knew from cultivation in Uppsala and from the literature. There are now perhaps 120 species in the genus, all from tropical and warm temperate zones (Mabberley 1997).

Bulbs are used to heal wounds and flowers are pectoral (Roig 1945). Several species in the genus are used in the Caribbean for a variety of ailments (Morton 1981).

Bulbs, and presumably other plant parts, contain lycorine, crinidine, crinamine, and other alkaloids (Perkins and Payne 1978). The Lubber grasshopper (*Romalea*

*microptera*), ranging from North Carolina to Texas, is adapted for using these poisons, and advertises its toxicity in its aposematic coloration (Capinera 2001).

***Crossopetalum*: Maiden-Berry**

(Based on Greek *krossos*, fringe, and *petalon*, petal, an allusion to their ornamented margins)

***Crossopetalum rhacoma*.** a. Flowering branch, b. Terminal bud, c. Leaf outline, d. Flower clusters, e. Flower, front-side view, at early (male) stage, f. Flower at male stage, longitudinally dissected, g. Flower, front-side view, at later (female) stage, h. Flower at female stage, longitudinally dissected, i. Floral diagram, j. Fruiting branch. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

Scattered through the pinelands of Miami-Dade and Monroe Counties are small shrubs some call Christmas-berry or maiden-berry. People apply these two names to different species of *Crossopetalum*, the first belonging to *C. ilicifolium* and the second to *C. rhacoma*.

We might expect the name “Christmas-berry” to be young, because that celebration is not that old (Austin 1998a). The word “Christmas” did not exist until 11 centuries after the time of Christ. Use of the name Christmas-berry goes back to at least the early 1900s,

although maiden-berry seems to be of more recent application. However, the combination of “maiden” with other words in plant names is a venerable practice, dating to 1589 or earlier. The meanings of “maiden” are varied in English and in the plant names, and why the word has been applied to Florida plants is uncertain. We might speculate that the red fruits were compared with the blushing cheeks of a young woman, but it could just as well be one of the other meanings. For example, two other ancient interpretations are a plant grown from seed and a plant that has not been budded, lopped, pruned, or transplanted.

Older names for *C. rhacoma* in Florida and in other English-speaking areas include poison cherry (USA, Bahamas, Jamaica, Puerto Rico), snake berry (Cayman Islands), tobacco berry (Cayman Islands), wild cherry (USA, Puerto Rico), and wild tobacco (Cayman Islands). In these names “poison,” “snake,” and “tobacco” are modifiers applied to any unknown fruit that resembles a known and usually cultivated type. In other words, those modifiers are equivalent to “wild.”

The comparison with fruits is also common in other parts of the Caribbean. For example, they are *palo de paloma* (dove tree, Puerto Rico), *pico de paloma* (dove beak, Puerto Rico), *palu di pushi* (*pushi* tree, Dutch Antilles), and *petit merisier* (little wild cherry, French Antilles). Comparisons with other species include *lemoncillo* (little lime, Cuba), *limonejo* (lime tree, Cuba for *C. latifolia*), *limonejo de costa* (coastal lime tree, Cuba), and *membrillo* (quince, *Cydonia oblonga*, Rosaceae).

Names even compare the fruits with candy, perhaps because of their bright red color. These include *bonbon rouge* (red candy, French Antilles), *coral* (Spanish), *ti bonbon* (little candy, Guadeloupe, Martinique), and *ti bonbon rouge* (little red candy, French Antilles).

There also are a number of obscure references. In Cuba the plants are called *jinca pata* (*pata*, foot), although I have been unable to find native speakers of Spanish who understand the word *jinca*. In the Dutch Antilles, *Crossopetalum rhacoma* is *kuragoga*, surely because of its similarity to the related species *C. uragoga*. One species is named *mala mujer* (bad girl, Puerto Rico for *C. latifolia*), although we do not know why she was bad. Elsewhere, *mala mujer* is used for thorny and (usually) stinging plants.

Also in Puerto Rico, *C. rhacoma* is *manto* (mantle), a name most often given to members of the Convolvulaceae that blanket others with their growth. Finally, there is *maravedi* (Cuba, Puerto Rico), which turns out to be another Arabic word in Spanish. Not only is that name applied to *C. rhacoma*, but in Cuba it is also applied to *C. uragoga* (see below). For some reason the word was taken from the name of an old gold coin and applied to these plants. Perhaps it was the similarity of the coin and the shape of the leaves.

Both of Florida's *Crossopetalum* species have extremely limited ranges, and both are considered endangered by the state (Coile 2000). Essentially, both species are confined to Miami-Dade and Monroe Counties, although historically *C. rhacoma* was also found in Broward, Palm Beach, Collier, Lee, and Sarasota Counties. Outside Florida, *C. rhacoma* ranges through the Bahamas, from Cuba to St. Lucia, Aruba, Bonaire, and Curaçao, and southern Mexico to Colombia and Venezuela. *Crossopetalum ilicifolium* has a similar range.

Both species of *Crossopetalum* have edible fruits, although each is small and not very filling. These small drupes are produced sporadically at least through the warm months

and soon disappear because they are greedily consumed by birds and other fructivores. The most widespread and common use made of these rare plants is for treating kidney problems (Morton 1981). Throughout the Caribbean, a root decoction is used to expel kidney stones, as a diuretic, and against bladder and kidney infections. In Cuba, a decoction of leafy branches and roots is taken hot or cold as a diuretic and to counteract kidney inflammation (Roig 1945).

Perhaps because the plants are uncommon and small (rarely exceeding 1 m tall, although they can grow to 5 m), little has been written about their uses. That should not diminish the favor they have been given in regions where they occur, at least in the Caribbean.

The Celastraceae, to which *Crossopetalum* belongs, is rife with taxonomic problems and confusion. Historically, what is now one genus was thought for decades to be three—*Crossopetalum*, *Rhacoma*, and *Myginda*.

*Crossopetalum* was created by Patrick Browne in his *The Civil and Natural History of Jamaica* published in 1756. Subsequently, Linnaeus rejected the genus in his *Systema Naturae* published in 1759, and created *Rhacoma* (Latin *rhacoma* or *rhecoma*, root, rhubarb from Pliny, A.D. 23–79; Greek, *rhakoma*, rags, *rhakos*, tattered garment). He applied the name *R. crossopetalum* to the species Browne previously had named in 1756. That action is considered illegal, as there was an available genus that Linnaeus should have used. Therefore, his *Rhacoma* becomes a synonym of the correct name, *Crossopetalum*. That legal aspect was not corrected until 1766 when Heinrich J.N.von Crantz (1722–1797), professor of medicine in Vienna, made the change. Crantz should have been followed, but for decades, people followed Linnaeus and used the genus *Rhacoma*.

The latest interpretation is that *Crossopetalum* and *Myginda* also are the same genus even though the *Flora de Cuba* and other publications recognized them as distinct. Apparently, the authors of the *Flora de Cuba* kept them apart based solely on having four locales in *Crossopetalum* and two in *Myginda*, leaving a single species in the latter genus.

*Myginda* was created in 1760 by Nicolaus K.von Jacquin to commemorate his friend, the Austrian botanist Franz Mygind (1710–1789). Jacquin's *M. uragoga* is now correctly *C. uragoga*. That species grows in Cuba, Puerto Rico, Colombia, and in Mexico from Veracruz and Oaxaca south, and apparently disjunct, to Nicaragua. As indicated by the species name *uragoga* (promoting urine), the plant had been famous as a diuretic in the Caribbean long before it was described in Europe. In Cuba, this is the *hierba [yerba] maravedí*, making that allusion to the old coin with an Arabic word.

The only information found on human uses of *C. uragoga* in Mexico was provided by Alcorn (1984). She recorded that the Huastec had several names for these plants. In San Luis Potosí they were usually called *ts'amuts' uxkwe'* (old lady's earrings). However, they also call them *tsakam itsal koox* (koox-large bird chile), *ts'amuxlaab ts'ohool* (earring plant), *ts'amuts'laab ts'ohool* (earring plant), *ts'amuts' uthu'* (monkey earrings), *tsatsa' ilaal* (*Hylocereus undatus* medicine), and *ts'amuts' an thakchaam* (Náhuatl earrings). In the Veracruz dialect they are *ch'amuxlaab te'* (earring tree) or *chakam granadillo* (little granadillo). The plants are used for dermatological problems including blisters, calluses, and corns. The bark and root are mixed with other plants (*Ehretia anacua*, *Lantana camara*) and used to stop hemorrhage associated with obstetrical problems. Roots and bark also are boiled and used in medicinal baths to stop pain

associated with dysentery and burning eyes. All of the applications are topical and not internal, differing markedly from the Caribbean use as a diuretic.

The family is noted for containing a variety of cardenolides, sesquiterpenes, and terpenoids. Several of those compounds have recently been found in the genus *Crossopetalum*. However, little is known about the chemistry of the genus. It is clear that the sesquiterpenes serve as deterrents to insect pests in the Panamanian species (Tincusi et al. 1998), and that cardenolides in the Mexican species are cytotoxic (Ankli et al. 2000). If similar chemicals occur in the Florida species, those traits would make them useful for several of the maladies they have been used to treat.

This group of medicinal plants is another whose application has almost been lost. Few people in the Caribbean and apparently in Mexico now seem to remember that there are curative traits associated with these small shrubs. Maybe we humans should blush like the maidens of maiden-berry's namesake at endangering useful organisms before we even know their potential.

### *Crotalaria*: Rattlebox

(From Greek *krotalon*, a rattle or castanet)

*Crotalaria pumila*. a. Branch of flowering and fruiting plant, b. Inflorescence, c. Flower longitudinally dissected, d. Standard (banner), e. Wing. f. Keel. g. Stamens united, h. Floral diagram, i. Pistil. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

Europeans were fascinated by plants from other parts of the world that produced fruits like rattles. Beginning in the 1600s, herbalist-physicians like Leonard Plukenet and Hans Sloane recorded these *Crotalaria* from the Americas. Others, including Hendrik van Rheede and Paul Hermann, noted them in India, elsewhere in Asia, and in Africa. Some say that these authors used a translation of the Sanskrit *ghantār avamu* to establish their Greek name *Crotalaria* (Watt [1889] 1972). Linnaeus continued using the established name for the genus when he published his *Species Plantarum* in 1753, providing the foundation of modern usage. He knew of 13 species, and that list has now grown to about 600 (Mabberley 1997).

At almost the same time that the Europeans were learning about rattlebox legumes, they were encountering another kind of rattling American. The first to record that one in English was Capt. John Smith, who wrote in 1630 about “the danger of the rattell snake.” It was not until 1759 that Linnaeus named that snake *Crotalus*, using the same Greek base word as *Crotalaria*. We now know that there are two genera of rattlesnakes (*Crotalus* and *Sistrurus*), but they are both poisonous pit vipers. The genus *Crotalaria* is also poisonous, and using the same base word for their genera was a good way of emphasizing that potential danger, although that was not Linnaeus’s primary intent.

Obviously, the plants and the saurian relatives are poisonous in different ways, and they have distinctive toxins. Most, if not all, members of *Crotalaria* contain pyrrolizidine alkaloids (Williams and Molyneux 1987, Deyo and Kerkvliet 1990, Nellis 1997). Some species, like *C. incana*, have retrorsine in the whole plant, which causes liver and kidney neoplasms, plus the alkaloid integerrimine in the seeds, which causes liver and lung lesions. A related plant, *C. retusa*, has both retrorsine and microcrotaline (Nellis 1997). Since several species are used as bush teas in the Caribbean, they can cause major health problems. Those problems are not confined to adults, but can be passed to infants through mother’s milk.

The snake, on the other hand, is highly evolved to deliver a mixture of poisons through hollow fangs serving much like hypodermic needles. Its poisons consist of enzymes, glycoproteins, polypeptides, and other chemicals that inhibit blood clotting and actually begin to digest tissues.

Additionally, the snake’s “rattles” too are derived in totally different ways. The rattle in the ophidian is partly the result of incomplete shedding of the skin and accumulations of horny materials at the base of the tail. When snakes are agitated, they vibrate their tails and they “rattle,” perhaps incidentally warning off organisms that possibly might otherwise step on the snake and harm it. The plants have legumes that become somewhat inflated when ripe, and their numerous small seeds detach from the placenta. When the plants are bumped or shaken by the wind, the seeds rattle against the walls of the dry fruits.

Shortly after I arrived in Florida, I had a student who decided to frighten the new professor. He knocked on my office door, stuck in his head, and said, “I have a present for you.” With his hand behind his back and out of view, he shook the dry fruits of *Crotalaria*. Because I knew that he was full of mischief, and because I was fascinated by snakes of all kinds, I replied, “Fine! Bring it in and let’s have a look.” The smile faded from his face and he entered to display the dried legumes. The sounds of the fruit and the rattlesnake are remarkably similar, and I could not distinguish them then or now. I have

been startled more than once in the field when I bumped into dry branches of *Crotalaria* and momentarily mistook them for *Crotalus*.

There are several *Crotalaria* introduced into Florida and nearby regions, including *C. incana*, *C. lanceolata*, *C. retusa*, and *C. spectabilis*. Burkill (1966) and others think that *C. incana* is native to the Americas, although a more exact provenance is not indicated. *Crotalaria lanceolata* is from South Africa; *C. retusa* is from the Old World tropics; and *C. spectabilis* was introduced by David Fairchild from the Old World when he worked for the U.S. Department of Agriculture. Throughout the native ranges of these species, they are used for a variety of purposes, with high-quality stem fibers used in ropes, strings, and fabrics. Those fibers have been substituted in some areas for the famous sunn hemp (*C. juncea*) of India. The second most widespread use of plants in the genus has been to provide a green-manure crop for fertilizing lands. Indeed, *C. spectabilis* was introduced by the U.S. Department of Agriculture in 1921 and touted as a soil conditioner and forage crop. Subsequently, it was discovered that the seeds were toxic, and even then some encouraged people to grow it to deter nematodes and other garden pests. According to them, if planted around garden species, the toxins in the leaves and stems discouraged aboveground pests and the poisons in the roots stopped nematodes from attacking below the ground.

Throughout the range of the genus *Crotalaria* in the Americas, the species often have common names alluding to the rattling dry seed pods. Perhaps the most famous to English-speaking people is shake-shake, mostly applied to *C. incana*. However, that species and others are known as *tcha-tcha* (onomatopoetic for the rattle sound) or *sonnette* (little bell) in the French Antilles. People in Belize call it wild-piss-a-bed. *Crotalaria pumila* is called *pois-savanne* (savanna bean), *pois-sonnette* (little bell bean), and *tcha-tcha* at least in Martinique and Guadeloupe. In Spanish areas the various species tend to be called *cascabelillo* (little bell), *matraca* (a type of musical instrument), or *sonajuelas* (little bells).

The American native species *C. incana* perhaps encouraged others to be used in curing rituals also. In several places in the Caribbean and in South America where the plants are called shake-shake, they are used to treat mute children. The reasoning seems to be that they will help “because the plant speaks” (Nellis 1997). Discussions with herbalists in the Guyanas indicate that they do not always distinguish between *C. incana* and several other species (Austin and Bourne 1992). Also, the widespread application of the “rattler” common names may denote lumping of similar species. Root teas from several species have been used in the Americas and the Old World to treat skin problems. The name *chipil* (Sonora) is probably related to treating skin diseases with *C. pumila*. That name seems to be based on *chipeliui* (Náhuatl), which refers to curing lesions caused by a skin disease.

Both *C. incana* and *C. retusa* are now in Florida, but they are not included in the native ethnoflora because they are aliens introduced within historic times. We do have one native that has been used. *Crotalaria pumila* appears in the vocabulary of the Seminoles as *casapó:cí* [*sacasapkó:cí*, *satecasapkotci*] (*svcvsakkv*, rattle, *o:cí*, small, Mikasuki). Those names are close if not identical to *shachachapkooche* (*svcvsakkv*, rattle, *oce*, little, Mikasuki) and *kvsvkakuce* (*kvsvkicetv*, rattle, *uce*, little, Creek) reported by Snow and Stans (2001) for *C. rotundifolia*. It may be that more than one species was

used. The Catawba called it *sé'sere?ha* (rattle) or *tapasi'sare* (something rattles), but they used it to treat mental problems and teething in infants (Speck 1934, 1944).

The Mikasuki name came from an unpublished 1941 manuscript used by Sturtevant (1955), but he found no informants who knew the plants. Perhaps any use previously known had been lost by his consultant, but Alice Snow now remembers it (Snow and Stans 2001). The people of Mexico still use it.

Names for the plants appear in Mexican languages. The Mayans of Yucatan know *C. pumila* as *sakpet* (*sak*, white, *pet*, small portion). The Mayan name is said to be used because the plants grow in small clumps that contrast with the other vegetation because of its whitish-green color. The plant is used in “small portions” as a condiment in some areas of Cozumel and perhaps elsewhere in Mexico (Valdez et al. 1989).

There are older records of people using the plants elsewhere in Mexico and Central America. A collection of *C. pumila* from Temascaltepec in the state of Mexico (George B. Hinton 1636 NY) made in 1932 notes, “edible, boiled with ripeseed” (von Reis and Lipp 1982, Hodgson 2001). The Zapotecs in Oaxaca gather *C. pumila* from maize fields and call it *sij* in their language or *chipil* in Spanish (Messer 1978). To distinguish it from *C. incana*, they call that wild plant *sij gihs* (wild *sij*) or *chipil de campo*. The young foliage is eaten, often made into *tamales de chipil* with dough from *maize de elote* (green corn). Similar use has been made in Guatemala (Macbride 1945 in Messer 1978).

Farther north in Sonora, the plants are *cascabel de víbora* (snake rattle), *bull de Díos* (God’s rattles, Guarijío), *huevitos del toro* (little bull “eggs,” usually a euphemism for testes), and *jojolino*. *Cascabel de víbora* notes the old similarity of the rattles in the plants and snakes. The Guarijío name alludes to a similar sound made by rattles during dances. *Jojolino*, however, seems to be a variant of *ajonjolí*, or sesame (*Sesamum indicum*). That common name, *ajonjolí*, is applied to *C. incana* in the Sonoran region (Hodgson 2001).

Seeds of *Crotalaria* and *Sesamum* are about the same size, and bear a slight resemblance to each other. Perhaps the common names comparing both these species to *Sesamum* are relics from past widespread utilization.

Knowledge of human usage in Sonora has almost ceased to exist, except for a few records. Gentry (1942, 1963) observed the Guarijío eating the seeds of *C. incana*, and also grinding the seeds of an unidentified species before eating them as *pinole*. Modern Guarijío recall that the plants were eaten but have never tried them (Yetman, Feb. 2002, personal communication, Yetman 2002).

The common names plus the records in Mexico suggest that the practice of eating the plants as a condiment or the seeds as *pinole* was previously more widespread. Perhaps the Seminoles learned the usage from their predecessors in Florida, the Glades people.

### ***Croton*: Grannybush**

(From Greek *kroton*, the name of “ticks,” noting the similarity of the seeds to those blood-engorged ectoparasites)

Start walking in the pinelands in the lower Florida Keys and you will find small herbs known locally as grannybush (Bahamas, Florida) or pineland croton (Florida). You find the same plants if you continue up the coast to Miami-Dade County. However, by the time you reach Broward County, the plants are gone. Just as you think they have

disappeared completely, they reappear in northern Palm Beach and Martin Counties. These pineland herbs have a disjunct distribution in southeastern Florida.

Technically, the herbs are *Croton linearis*, and they usually grow up to about 1 m (3 feet) tall. Wherever they grow, they are the unique host for the Goatweed butterfly (*Anaea andria*), so its colonies are similarly disjunct.

In the neighboring Bahama Islands, the herbs may be called bay wormwood, marigold, or muckle (mispronunciation of “myrtle”). The plants grow throughout the islands and are not always associated with pinelands. There, as in Jamaica, they tend to be on limestone substrates. Maybe it is the overburden of

***Croton linearis*.** a. Fertile branch, b. Staminate flower, side view, c. Staminate flower, longitudinally dissected, d. Floral diagram of staminate flower, e. Pistillate flower, side view, f. Pistillate flower, longitudinally dissected, g. Floral diagram of pistillate flower, h. Fruiting branch. *Drawn by Priscilla Fawcett.*  
From Correll and Correll 1982.

acid to neutral sands that prevents them from being in Broward and most of Palm Beach Counties.

In classical Greek literature, the word *kroton* referred to plants and to the ectoparasitic arachnid we call a tick (Anglo-Saxon *tica*; also Greek, *zecke*; Germanic about A.D. 800 and equated with *ricinus*). When Linnaeus came to study the plants, he discovered the old confusion of naming plants and the parasitic animal with the same word.

There were other classical words available. For example, Romans such as Pliny (A.D. 23–79) also used *ricinus* (diminutive of Latin *rica*, little veil) to indicate what we now call the castor bean. Linnaeus continued that application with *Ricinus communis*.

Most of the earlier botanist-herbalists had used *Ricinoides* (resembling *Ricinus*) for the other group of plants. Linnaeus needed a better word to distinguish between these two different kinds of plants, and so he adopted the old Greek *kroton*. Both names now designate distinct members of the spurge family, Euphorbiaceae. To end the confusion with animals, he called the most common tick genera *Dermacentor* (Greek, skin-piercer) and *Ixodes* (Greek, *ixod*, bird-lime, because they stick to the skin).

Anyone who has ever tasted, or even seen anyone taste, castor oil knows that there are incredibly foul chemicals in the liquid. The same may be said for extracts of *Croton*, and seeds in both genera contain oils that may be lethal if ingested in the wrong quantities. In spite of their inestimably poisonous nature, people have used extracts from seeds of both plant genera as medicines for thousands of years. Some species of *Croton* contain oil that can be lethal if as few as 20 drops are ingested.

One famous medicinal species is Asian *C. tiglium*, which has up to 30 to 50% oil. In the oils are compounds that have been called “croton,” but they are actually two phytotoxins (Hocking 1997). Properly diluted, these oils have been used as laxatives longer than history records. The oil and its constituents (including resins containing phorbol, tiglic acid, and other compounds) are drastic cathartics in humans, and expel worms in domestic animals. That oil has been used as an epispastic, and by malingerers to simulate skin diseases because it is a vesicular counter-irritant and corrosive (Hocking 1997). The croton oil is also found in leaves and stems of many species but in lesser quantities. The compound itself is not carcinogenic but may augment carcinogenesis initially induced by aromatic hydrocarbons, at least on the skins of mice (Lewis and Elvin-Lewis 1977). The compounds in the seeds also have tumor-inhibitory properties.

From this extreme species, the other end of the spectrum of chemical constituents and human uses is *C. eluteria* (cascarilla bark, sweet bark, sweetwood bark, Eluthera bark, Bahamas). That plant has been used to flavor liqueurs (quinine substitute), mixed as an aromatic with tobacco, and as a fumigant (Morton 1981). Until about the 1920s, it was part of the U.S. Pharmacopoeia and U.S. National Formulary. These plants contain the volatile oils eugenol, limenone, vanillin, cascarillin, and they are bitter, tonic, and spicy.

*Croton linearis* was not named until 1760, after being discovered by Nicolaus von Jacquin. People living where it grows find it closer in the chemical spectrum to *C. eluteria* than *C. tiglium*. In fact, grannybush has been used as an adulterant for cascarilla bark.

John K. Small (1933) recorded that people in Florida used grannybush as a tea. That must have close to the end of the time it was used there because no usage has been found in the state since. However, people continue to use it in the Bahamas, Cuba, and Jamaica. They consider the plant decoction a remedy for colds, fevers, rheumatism, stomach trouble, menstrual cramps, and insect bites. To make the brew for insect bites, the plant is boiled longer to make it particularly strong (Morton 1981).

This is an important medicine for women’s problems. Old grandmothers are its primary prescribers, and that is how it got the name “grannybush.” For those purposes, the plant is tied in a bundle and boiled with rum. The resultant mixture is given as a refreshing, restorative drink to new mothers for 9 days after they give birth. To reduce

fever, patients are bathed with a combined decoction of the plant and *Pluchea carolinensis*. Jamaicans use a hot bath of *C. linearis*, which they call rosemary (Caymans, Jamaica), to relieve colds. Formerly, the dried powdered leaves were prescribed in Jamaica as a remedy for colic. Jamaicans also use it, as they do true rosemary (*Rosmarinus officinalis*), in washing their hair.

The Jamaican common name is related to comparisons with rosemary elsewhere. For example, in the Dominican Republic it is *romarin* (false rosemary). Cubans say *romero de costa* (coastal rosemary). Others may say it is Spanish rosemary or wild rosemary (Bahamas, Jamaica). Those names, and *Croton* substitution for rosemary, are perhaps related to the Creole French name *trop faire pain mourri* (make too much bread, and you will die, Haiti).

Other names in the Caribbean are more obtuse and obscure. For example, in Haiti it is called *copahy*, a word whose meaning is unknown. Perhaps *copahy* was derived from Taino *cabs*, often rendered as *capá* (Coll y Toste 1972). Although it does not sound like it, the name *escupe culebra* (snake spit, Dominican Republic) alludes to a medicinal use. Surely, the appellation sassparilla does the same. For decades after its discovery in the Old World, all *Smilax* roots were called either China root or sassparilla (see *Smilax*: Green-Briar). There is no obvious similarity between *Smilax* and *C. linearis*, so the allusion must be to their uses as beverages or medicines.

The name *tremolino prieto* (black little trembler, Dominican Republic) may indicate the plants blowing in the breeze, but more likely that is another medicinal comment. That suggestion is made more probable when it is noted that several species of irritant *Croton* and *Oxalis* are called *tremolino* in Hispaniola. Moreover, the people there separate *tremolino prieto* from *tremolino blanco* (applied to *Corchorus hirsutus*, *Croton discolor*, and *Phoradendron anceps*).

Grannybush contains a series of alkaloids. Among those alkaloids are bases A (pronuciferine, *N,O*-dimethyl-crotonosine), B, and E. The plants also contain 8,14-dihydronorsalutaridine, 8,14-dihydrosalutaridine, linearisine, and pronuciferine. Plants are able to create crotonosine from linearisine (Willaman and Hui 1970). Additionally, proaporphine and aporphine alkaloids have been characterized (Casagrande et al. 1975), as has a diterpene with insecticidal properties (Alexander et al. 1991).

Of the 750 or so species in the genus *Croton* (Mabberley 1997), a surprisingly large number have been used by people. Most (possibly all) of the plants are apparently chemical factories for a complex of compounds. Extracts range from the most drastic laxative known (*C. tiglium*), to palatable and healthy beverages (*C. linearis*), flavor additives and enhancers (*C. eluteria*), host plants for lac insects (*C. laccifer*), hosts for butterflies (*C. linearis*), and as a source of timber (*C. megalocarpus*), and wound-healing chemicals (*C. lechleri*, Porras-Reyes et al. 1993). Hocking (1997) lists 36 species that have been used worldwide, and Moerman (1998) lists five for temperate North America.

Still, ingestion of *Croton* is a gamble that you have identified the species properly. One species is lethal, and another provides pleasing teas. Perhaps too many mistakes occurred and that is why grannybush is no longer used in Florida.

*Ctenium*

(From Greek *kteis* or *ktenos*, a comb, diminutive *ctenion*, a small comb, from the appearance of the flower spike)

***Ctenium aromaticum*.** Drawn by Mary Wright Gill and Agnes Chase. From Hitchcock and Chase 1950.

***Ctenium aromaticum*** (fragrant)

tooth-ache grass [toothache] (first located in Williams [1837] 1962)

*Ctenium* was named in 1813 by German taxonomist Georg Wolfgang Franz Panzer (1755–1829), who called the grass *C. carolinianum*. Technically that species name is a synonym of *C. aromaticum*, because Walter had named it in another genus in 1788. However, Panzer's *C. carolinianum* was used until the principal at the Brooklyn Female Academy, Alphonse W. Wood (1810–1881), made the correction in 1861. As now known, *Ctenium* has 17 species confined to the Americas and Africa. Not only is the widespread North American *C. aromaticum* in Florida, but *C. floridanum* is endemic to the northeastern part of the state. Like wiregrass (*Aristida beyrichiana*) with which *Ctenium* grows, it flowers only after fires burn through the pinelands (Mabberley 1997).

No actual records of human use of *Ctenium* for toothache have been found. However, the common name suggests that its pungent taste has been used to relieve that problem. Moreover, Williams ([1837] 1962) wrote, "It affects the breath and milk of cows, who eat it when young and tender. The root is bitter, and affects the salivary glands." Hocking (1997) also indicated that the grass has been used as a sialagogue (to increase saliva flow). Fernald (1950) noted that the bruised roots are fragrant, perhaps containing some of the same chemicals as aboveground parts. Gamboa-Leon and Scott-Chilton (2000)

identified isobutylamide as the numbing agent. Barkworth (2003) wrote, “The roots are spicy when freshly dug.”

### *Cucurbita*

(Classical Latin name for the bottle gourd, *Lagenaria*; reapplied by Linnaeus to the New World plants)

***Cucurbita okeechobeensis*** (from Lake Okeechobee)

*ciko:yi* (Mikasuki)

Okeechobee gourd (Florida)

***Cucurbita pepo*** (originally ripe or tender, but later applied to the melon as Latin *pepo* and Greek *pepon*)

**Pumpkin** (derived from Old World Greek *pepon* or Latin *pepo*, for a New World plant; *Pepon* evolved into French *pompon*, Italian *popone*, and Portuguese *abóbora* and finally reached English as “pumpkin” ca. 1654); *abóbora* (from *pepon*, Portuguese); *peapag* (from *pepon*, Gaelic)

*calabaza* (derived from Arabic *qar’ah yábisah*, dry gourd, a name originally for *Lagenaria*, Spanish, Mexico to Peru)

*cocuzza* (slang, originally for *Lagenaria*; probably locally applied to *Cucurbita*, Italian)

*courge* [*gourde*] (from *Cucurbita*, French)

*giromons* [*giraumon*] (*giraumont* was in use by 1734; then, Le Paige Du Pratz used it in Louisiana in 1758, mostly used for *C. maxima* and *C. moschata*; from Tupí *yuru’mu*; French, Louisiana); *jerimum* [*jerimu*, *jerumu*, *jirimu*, *jirumum*, *jurumu*, *gerimum*, *gurumu*, *girimu*, *girumum*] (from Tupí, maybe first used by Piso and Marcgraf in 1658, Portuguese, Brazil)

*Kürbis* [*Kirbiz*] (German)

*zucca* (originally for *Lagenaria*, later extended to *Cucurbita*, Italian)

**Squash** (came into English from two directions: The older meaning, from ca. 1565, came from Latin *quassare*, to crush; the younger derivation, for *Cucurbita* fruits, came from Algonquian words appearing in print ca. 1634 as *isquouter-squashes*, with variant spellings as *squanter-squash*, or *squoutersquashes*; Hedrick 1919)

*abóbora* (from *pepon*, Portuguese)

*anta ahonni* (“pumpkin with rind bent,” for crook-necked squash, Biloxi)

*calabaza* (originally used for *Lagenaria*, Spanish)

*citrouille* (in use as “*sitroules*” by Champlain in New England in 1605; resembling *Citrus*, French)

*cushaw* (winter squash with a curved neck; akin to Algonquian *askushaw* or *escushaw*, it is green, appearing by 1588; probably a word related to a root called *coscúshaw*; see *Peltandra*)

cymling [cimnel, simnel, simnel-gourd, simblin, simlin, symnels] (Hedrick 1919 thought this might be a native American word for white, scalloped squash, also called the pattypan; perhaps from Old French *simenel*, or *seminel*, maybe related to Latin *similia* and Greek *semidalis*; in use by 1648 at the mouth of the Susquehanna River; cymling in use by 1794, and Thomas Jefferson wrote cimnel in 1803)

*Kürbis* (from *Cucurbita*, German)

[vegetable] marrow (squash, from Old English *mearg*, of Teutonic origin; applied to *Cucurbita* by 1816)

*zucca* (Italian)

**Gourd** (from Middle French *gourde*, itself from *Cucurbita*; the diminutive of *gourde* or its variant *courge* is *courgette*, French)

calabash (from French); *calabasse* (French); *calabaza* (derived from Arabic *qar'ah yábisah*, dry gourd, a name originally for *Lagenaria*, Mexico to Peru, Spanish)

*cetriolo* (gerkin [and gourd?], Italian)

*cocomero* (watermelon [and gourd?], Italian)

*Flaschenkürbis* (bottle gourd [pumpkin], German)

**Melon** (from French *melon*, in use by A.D. 1387, when “melon” appeared in English); *melão* (Portuguese); *meloen* (Dutch); *melon* (from Latin *melopepo*, French, Spanish); *Melone* (German); *melone* (Italian)

### North America Languages

*askútasquash* (eaten raw, Natick and Narragansett, Connecticut and Rhode Island)

*atowetowe-w* (cymbling or summer squash, Powhatan, Virginia; Strachey in [1612] 1953 recorded the name as *autowtaoh*, and translated it, “an ear of wheat”; Siebert 1975 found cognates in Penobscot as *atówatawan*, and *atówatawe*; at least the first element of the Narragansett *askútasquash* is cognate)

*casila:nî* (loan-word from the Spanish *castillano*, Creek)

*choksi* (squash, but especially winter squash, Alabama); *coksí* (Koasati, Mikasuki); *coksláknî* (*coksí*, squash, *lákni*, yellow, any yellow squash, Mikasuki); *cokslakno:cî* (little yellow pumpkin, Mikasuki); *cvse* [*cv'se*, *chasi*, *chassa*] (pumpkin, Creek, Muskogee); *kochi* (gourd, Alabama); *lokosh* (Chickasaw); *tvhóyv* [*tvhvyv*] (squash, Muskogee); *choksiáyvi* (*choksi*, squash, *tayvi*, woman, Alabama); *choksichàakka* [*choksichàka*, *choksichakka*] (*choksi*, squash, *chàakka*=? *chàachi*, older brother; cushaw, a large, long-necked, striped squash, Alabama); *choksilaana* (any yellow squash, but especially pumpkin; *choksi*, squash, *laana*, yellow, Alabama); *choksihakhachi* [*choksihakhachi*, *choksihakhachi*] (*choksi*, squash, *hakhachi*, becoming white-haired [striped squash, cushaw], Alabama); *isito* (Choctaw); *isito holba* (squash; *isito*, pumpkin, *holba*, resembling, Choctaw); *olbi'* (squash, Chickasaw); *ostahi* (squash, Chickasaw); *osto* (pumpkin, Chickasaw); *yátkitiscíncoksî* (Indian's pumpkin, Mikasuki)

*efêpe, fêpe* (gourd, Muskogee)

*gescundhàckall* (Delaware)

*i-ya [iya]* (pumpkin, Cherokee)

*macócqwer* (included pumpkins, melons, and gourds, Carolina Algonquians); *máhkahkw* (pumpkin, Delaware; the word is cognate with other Algonquian languages where it means “tub, cask, box, keg” or “container”; those words include Cree *mahkahk*, Fox *mahkahkwi*, Menomini *mahkan*, Ojibwa *makkakk*, and Shawnee *mkaʔkwi*); *mahkahk* (Capt. John Smith and Strachey in [1612] 1953 also wrote it as *macock makokos*, *makawke*, and *mahcawk*, Powhatan, Virginia; Strachey’s word *macaugsaunesmes* should be translated “pumpkin seeds”)

*mo ’yum [mo ’yu]* (Atakapa)

*osaw’puk* (Plains Cree); *owgíssimaú’n* (tangled hairs, referring to the placenta, Potawatomi)

*patnga* (Hopi)

*pemesk* (Strachey wrote *pamyack* in [1612] 1953; Siebert 1975 suggests that the word is cognate with *wi-ne-mehkwan* in Menomini; this same tribe has transferred the word to the introduced watermelon, *Citrullus lanatus*, as *aski-mehkwan*)

*quaasiens* (in 1642–1653, Van der Donck said, “a name derived from the aborigines,” maybe from *askútasquash*, New York)

*tocobago* (has been translated as “place where gourds are produced,” Timucua?)

*wa’tap hany’?* (pumpkin seed, Catawba)

*wamnu* (pumpkin and squash, Dakota); *wagamun* (pumpkin and squash, Teton); *watan* (pumpkin and squash, Omaha-Ponca); *wa-ton* (Osage); *watan hti* (real squash, Omaha-Ponca); *watan miha* (small, spherical, spotted black and green, Omaha-Ponca); *watan nide bazu* (large oval, pointed at both ends, greenish color, Omaha-Ponca); *watan kukuge* (speckled, Omaha-Ponca); *watan niha snede* (long *watan miha*, Omaha-Ponca); *watan miha ska* (white *watan miha*, Omaha-Ponca); *watan miha saba* (black *watan miha*, Omaha-Ponca); *watan miha zi* (yellow *watan miha*, Omaha-Ponca)

## Middle American Languages

*apí* (Bribri, Costa Rica)

*ayotero* (the plant, Náhuatl, Mexico through El Salvador and Guatemala)

*ayotli [ayote]* (pumpkin or squash fruit, Náhuatl, Mexico through El Salvador and Guatemala)

*bát* (Brunka, Costa Rica)

*caay ixám* (horse’s gourd, Seri, Sonora)

*calabaza* (pumpkin, derived from Arabic *qar’ah yábisah*, dry gourd, a name originally for *Lagenaria*, Spanish, Mexico to Peru)

*chichicayotli* (*chichi*, bitter, *ayotli*, squash, Náhuatl, Mexico)

*chiverres* (Costa Rica)  
*gueto bichim* (*gueto*, squash, *bichim*, deer, Zapotec, Oaxaca); *gueto* or  
*giht* (pumpkin or squash, Zapotec, Oaxaca)  
*ka* (pumpkin and squashes, Maya, Yucatan)  
*ma she* (gourd, Tarahumara, Chihuahua); *ma 'she'* (pumpkin or squash  
 plant, Chinantec, Oaxaca)  
*moe* (Cuna, Panama)  
*nu* (Jicaque, Honduras)  
*pís* (Cabécara, Costa Rica)  
*póri-chla* (Guatuso, Costa Rica)  
*xam* (*Cucurbita*, Seri, Sonora); *xam cozalc* (ribbed squash, *C. pepo*,  
 Seri, Sonora)

### South American Languages

*auyama* [*ahuyama*] (pumpkin, first learned when Columbus arrived on  
 Terra Firme, fide Sauer 1969, Arawak); *uauíama* (pumpkin, Carib)  
*zapallo* (from *sapallu* or *zapallu*, mostly used for *C. moschata* and *C.*  
*maxima*, Quechua, Mexico to Panama)

There is a small park preserving the site of a historic indigenous village visited by the early Spanish on a peninsula west of Tampa Bay. The place was known as *Tocobago*, which been translated as “place where gourds are produced” (Fontaneda [1575] 1944). Maybe in part that translation is why John K. Small (1922) thought that southern Florida was the “Garden of Eden” for the pumpkin (*Cucurbita pepo*) and its relative the Okeechobee gourd (*C. okeechobeensis*).

The Okeechobee gourd is native to Florida, but its closest relative, *C. okeechobeensis* ssp. *martinezii*, grows in Mexico (Walters and Decker-Walters 1993). That means that the closest relative to the Okeechobee gourd is native to Chiapas, Oaxaca, San Luis Potosí, and Veracruz. If that were the only native gourd in Florida, it would be intriguing enough, but there is another species. That other species is *C. pepo*, the one that comprises the gourds, pumpkin, and squashes.

Columbus's arrival in the Caribbean in 1492 marked the Europeans' first encounter with the genus *Cucurbita*. This New World genus produced fruits similar to those of cucumbers and watermelons that the Spanish knew at home, but the explorers noted the differences. Columbus called *Crescentia*, *Cucurbita*, and *Lagenaria* by the only name he knew—*calabazas*, and he probably found all three in Cuba (Sauer 1969). That he did find *Cucurbita* there is indicated by his comment that these plants were “more delicate and lacking the little spines that the plant of the *calabaza* [*Lagenaria*] has.”

The first historical record of *Cucurbita* in Florida was from the expedition of Pánfilo de Narváez in 1528 (Swanton 1939). After passing through *Apalachee* and what is now Tallahassee, the Spanish encountered squashes in the land of the *Ante* [*Ochete*] near what is now known as Wakulla Springs (Wakulla County) in the Florida Panhandle. This is probably the locality where Alvar Nuñez Cabeza de Vaca (1490–1564) recorded the following in his *Relaciones* of 1555: “About their howses they have commonly square plots of cleered grownd, which serve them for gardens, some one hundred, some two

hundred foote square, wherein they sowe their tobacco, pumpons, and a fruit like unto a musk million [*Cucumis melo*], but less and worse, which they call macock gourds [*Cucurbita*], and such like, which fruiets increase exceedingly, and ripen in the beginning of July, and contynue until September; they plant also the field apple, the maracock [*Passiflora incarnata*], a wyld fruit like a kind of pomegranett, which increaseth infinitlye, and ripens in August, contynuing untill the end of October, when all the other fruits be gathered, but they sowe neither herb, flower, nor any other kynd of fruiet” (Gilmore 1919).

Many variations of *C. pepo* were developed by prehistoric people (Cutler and Whittaker 1961), and two lineages were brought into cultivation. The most famous lineage of pumpkins (*C. pepo* ssp. *pepo*) was domesticated in Mexico, but the other subspecies, which includes various squashes and ornamental gourds, was domesticated in the eastern United States (Decker 1988, Decker-Walters et al. 1993). *Cucurbita pepo* ssp. *ovifera* includes scallop and crookneck squashes and most ornamental gourds. The oldest record of this subspecies in Florida was as a wild plant at the end of the Pleistocene, and it has been in cultivation in the eastern United States since 5500 ( $\pm 1500$ ) B.P. (Newsom et al. 1993, Fritz 2000b).

Squashes and pumpkins are cultivated lineages of *C. pepo*. There are summer squashes, winter crook-necked squashes, autumn squashes, and autumn pumpkins. To make it more confusing, the marrows or vegetable marrows are in the same group. The “Seminole pumpkin” (*C. moschata*) is an introduction of a plant domesticated in Mexico (Robinson and Decker-Walters 1997). Apparently, the ancestors of the Seminoles brought this variety into cultivation.

Investigations of two kinds of gourds unearthed in the late 1890s turned up an unexpected southern record for *C. pepo* ssp. *ovifera*. The other gourd was *Lagenaria siceraria*, the bottle gourd. Those remains of pre-Columbian gourds had been found by the flamboyant and sometimes controversial Frank Hamilton Cushing.

In May of 1895, Cushing became convinced that Colonel W.D. Collier’s garden had been inhabited by prehistoric people. So, in February of 1896, he returned to excavate the site on Marco Island in Collier County. When he did, he uncovered some of the most spectacular botanical finds in North America (Cushing 1897).

While Marion S. Gilliland (1975) was preparing her study of Cushing’s material in the 1970s, she called in renowned cucurbit expert Hugh C. Cutler of the Missouri Botanical Garden. Cutler quickly realized that the material was the first ever found of *C. pepo* south of Kentucky in the United States (Cutler 1975). *Cucurbita pepo* was one of two species of gourds used by the Calusas, who probably abandoned Marco Island in the late 1400s, just before the Spanish arrived.

The English names for these plants are themselves confusing. We use the word “pumpkin,” derived from Old World Latin *pepon* or *pepo*, for a New World plant. The Latin *pepon* evolved into French *pompon*, Italian *popone*, and Portuguese *abóbora*. It finally reached English as “pumpkin” after being spelled *pepone* (1545), *pepon* (1578), *pompon* (1586), *pompion* (1588), and *pumpion* (1606). *Pepon* was even incorporated into Gaelic as *peapag*.

Originally, *pepo* simply meant “melon” and either referred to the “watermelon” (*Citrullus lanatus*) or “muskmelon” (*Cucumis melo*), or both. Those two genera are native to Africa and reached Europe long before the Americas were known. People in

Europe knew the New World *Cucurbita* looked like the familiar melons, but at first they did not have words to distinguish them.

“Melon” itself is a word almost unrecognizable in the older literature. That is what Harriot ([1590] 1972) meant when he wrote “Mellions,” and what Strachey meant in the 1600s with “million.” Indeed, the literature from A.D. 1387, when “melon” appeared in English, also included the spellings *melone*, *million*, *milon*, *myllon*, *milion*, *mellon*, *millon*, *million*, *mealon*, *meloune*, and *millean*. In other European languages, they are *melon* (French, Spanish), *melão* (Portuguese), and *melone* (Italian).

The word “squash” came into English from two directions. The older meaning (ca. 1565) came from Latin *quassare*, to crush. The younger derivation, for *Cucurbita* fruits, came from New England. These Algonquian words appeared in print in 1634 as *isquouter-squashes*, with variant spellings as *squanter-squash*, or *squouter-squashes* (Hedrick 1919). Those names were from *askútasquash* (Natick and Narragansett, Connecticut and Rhode Island), which means “eaten raw” (Robinson and Decker-Walters 1997). Roger Williams, in 1643, was one of the first to record *askútasquash*, and he added, “their vine apples—which the English from them call squashes; about the bigness of apples of several colors.” John Josselyn wrote in 1672 that these were “a kind of mellon or rather gourd, for they sometimes degenerate into gourds. Some of these are green, some yellow, some longish, like a gourd; others are round, like an apple; all of them are pleasant food boyled and buttered, and season’d with spice. But the yellow Squash, called the apple Squash, because like an apple, and about the bigness of a Pomewater [a large apple], is the best kind. They are much eaten by the Indians and the English.”

Van der Donck, speaking of the fruits in “New Netherlands” in 1642–1653, added, “The natives have another species of this vegetable peculiar to themselves, called by our people *quaasiens*, a name derived from the aborigines, as the plant was not known to us before our intercourse with them. It is a delightful fruit, as well as to the eye on account of its fine variety of colors, as to the mouth, for its agreeable taste.... It is gathered in summer, and when it is planted in the middle of April, the fruit is fit for eating by the first of June. They do not wait for it to ripen before making use of the fruit, but only until it has attained a certain size. They gather the squashes, and immediately place them on the fire without any further trouble” (Hedrick 1919).

Historically, people used ripening time to distinguish between pumpkin and squash—squashes produce a summer vegetable; pumpkins ripen only in the fall. Gourds have bitter instead of sweet flesh, and a hard, somewhat woody rind. However, Robinson and Decker-Walters (1997) point out that this will not work. They define squash as all cultivated *Cucurbita*. These they divide into the summer (including marrow) and winter squashes depending on whether the fruit is used when immature or mature. The term “winter squash” refers to the ability of the fruit to be stored until the winter months. Summer squashes are typically *C. pepo*, but the winter squashes may be one of four species (*C. argyrosperma*, *C. maxima*, *C. moschata*, or *C. pepo*). Gourd is any cucurbit not used as food. The hard shell is not characteristic because many summer squash cultivars have a hard rind when mature; they are simply eaten before ripening.

If this confusion of names were not enough, the Spanish began calling pumpkins *calabaza* (derived from Arabic *qar’ah yábisah*, dry gourd, a name originally for

*Lagenaria*, Mexico to Peru) or *zapallo* (from *sapallu* or *zapallu*, Quechua, Mexico to Panama; mostly used for *C. moschata* and *C. maxima*).

When Linnaeus tried to unravel all this babble of words, he settled on *Cucurbita* for the New World plants although it was the old Latin name for what we now call *Lagenaria*. From the word *Cucurbita*, we got the English “gourd” by way of Middle French *gourde*.

The uses for pumpkins, squashes, and gourds are many and varied. First and foremost, they are food. There are as many ways to eat them as there are people, and humans have selected a dazzling array of cultivars. Typically, the fall-fruiting, orange-fleshed types include pumpkins and acorn squashes. Those with lighter-colored flesh tend to be called squashes, including zucchini. Gourds come in many colors and shapes and now are mostly ornamental. The type called finger gourd, crown-of-thorns gourd, the gourd of the Ten Commandments, or the holy gourd is arguably the most unusual. There are also warted gourds, star gourds, and bicolored spoon gourds.

Fruits are boiled and baked as vegetables or used in soups, and they are also dried, ground into flour, and made into bread. Young shoots and leaves are cooked as greens. Flowers with the pistils removed are cooked and eaten or stuffed with meat and rice. Squashes and pumpkins also serve ceremonial purposes in many indigenous North American groups.

Cabeza de Vaca was already dead when Harriot ([1590] 1972) noted that the Carolina Algonquians called these plants “*Macócqwer*, according to their severall formes called by vs, *Pompions*, *Mellions*, and *Gourdes*, because they are of the like formes as those kindes in England. In Virginia such of several formes are of one taste and very good, and do also spring from one seed. There are of two sorts; one is ripe in the space of a month, and the other in two months.”

According to Strachey, in the 1600s Virginia people “seeth a kind of *million* [melons], which they put into their walnut-milke, and so make a kynd of toothsome meat.” Robert Beverley added in 1705 that people in the same area called the summer squash *macock*, which they “boil’d whole when the Apple is young, and the Shell tender, and dished with Cream or Butter, relish very well with all sorts of Butcher’s Meat, either fresh or salt. And whereas the Pompon is never eaten till it be ripe, these are never eaten after they are ripe.”

By 1758, Le Page Du Pratz may have been recording a Creole preparation of pumpkins (as *giromons*). He wrote, “they are cut into the shape of pears or other fruits and preserved thus with very little sugar, because they are naturally sweet. Those who are unacquainted with them are surprised to see entire fruits preserved without finding any seeds inside. The *giromons* are not only eaten preserved; they are also put into soups. Fritters [*bignets*] are made of them, they are fricasseed, they are cooked in the oven and under the embers, and in all ways they are good and pleasing.”

Seeds alone are also used as medicine throughout much of the Americas. Typically, the seeds are given to children to rid them of intestinal worms. The active compound is cucurbitin, a water-soluble, non-proteineogenic amino acid (Dunhill and Fowden 1965). Besides being useful for those worms, the substance inhibits growth of immature liver flukes, *Schistosoma japonicum*, at least in culture (Fang et al. 1961). The bitter components are tetracyclic terpenes called cucurbitacins. These are antitumor compounds and are applied to ulcers that are difficult to heal. There is even evidence that the

cucurbitacins may help with benign prostatic hyperplasia (BPH) (Swerdlow 2000, Duke et al. 2002).

Florida people had dry-fleshed gourd varieties that served as floats, rattles, and containers. The Calusa and probably other groups used the dry fruits as floats on nets they made from palm leaf fibers for fishing. In the 1560s, French artist Jacques Le Moyne found the Timucua using “two other rattle pumpkins filled with small stones or seeds” (Gilliland 1975). Jonathan Dickinson, the Quaker castaway on Florida’s south-eastern coast in 1699, recorded the Ais also using gourds as rattles and as containers for making black drink (*Ilex vomitoria*) (Andrews and Andrews 1945). All three tribes probably used gourds like those identified by Cutler (1975) from Marco Island.

The pumpkin is among the most famous of the gourd relatives because it is eaten and used at Halloween. Its use as a Jack-o’lantern at Halloween came into existence long after the Europeans came to the Americas. Celebrating Halloween is an Old World Gaelic event, and the Jack-o’lantern commemorates a man who bargained with the Devil. Since the Irishman kept outwitting the Devil and not delivering up his soul, the King of Darkness became angry. So, Mephistopheles damned the Irishman to eternal wandering. Before the man left, he dipped a turnip he had been eating into the coals of Hell. Now, he forever carries that torch before him at night.

Because turnips are poor lights, inventive Irish or Irish-Americans substituted the pumpkin for the turnip. A hollow lantern makes a better light. Now, the Old World legend and the New World plant are wedded in a custom that masks the origins of both elements.

### *Cuscuta*

(From Arabic *kusuta*, *kshuta*, *keskhut*, or *kusu*, “a tangled wisp of hair”; a loan word from Aramaic *kesatha*; see Austin 1979)

*cabellos de Venus* (Venus’s hair, Spanish); *cabelos* (hair, Portuguese); *cabelos de Jesus* (Jesus’s hair, Brazil)

*chetto em vpette* (*chetto*, snake, *em*, its, *vpette*, shadow, Muskogee); *chetto entopv* (*chetto*, snake, *em*, its, *topv*, table [Oklahoma], bed [Florida], Creek)

*lucv em pvtakv* (*lucv*, turtle, *em*, its, *pvtakv*, pallet, Muskogee); *lucv em vpette* (*lucv*, turtle, *em*, its, *vpette*, shadow, Muskogee)

*cuscuta* (Italian, Portuguese); *cuscute* (French)

dodder (in use in English by A.D. 1265, and with cognates in German *Dotter*, Dutch and Danish *dodder*, and Swedish *dotra*; originally meaning yellow, as in the yoke of an egg; the word “dodder,” as now used in English to mean

**Cuscuta.** *Cuscuta americana* (left), a. Section of flowering and fruiting stem. b. Flower bud. c. Flower from above, d. Flower, side view. e. Flower longitudinally dissected, f. Inner surface of corolla spread, showing the fringed scales and anthers, g. Floral diagram, h. Fruit below; detached corolla above. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982. *Cuscuta compacta* (top right). From Britton and Brown 1898. *Cuscuta gronovii* (lower right). From Britton and Brown 1898.

“tremble,” was not applied until 1627, and has a completely different etymology from “totter”)

golden-thread

love vine (in use by 1885; however, “love-bind” was used by John Parkinson for *Clematis* in 1640)

*Siede* (German)

*snyltetråd* (*snylte*, parasite, *tråd*, thread, Norwegian)

strangle weed (originally applied to *Orobanch*e by 1562; soon afterward used for *Cuscuta europaea*)

*vamad giikoa* [*vammatt geekwa*] (snake headdress or crown, Akimel O’odham [Pima], Arizona); *vamad givud* (snake belt, Akimel O’odham, Arizona); *vamad vijin* (snake spider’s web, Akimel O’odham, Arizona)

*wegei washai* (reddish grass, Tohono O’odham [Papago], Arizona)

***Cuscuta americana*** (of America)

*abrazos* (hugs, Spanish)

*aletria di mondi* (*aletria*=?, *di mondi*, world's, Netherland Antilles)

*amitié* [*l'amitié*] (lover, Haiti, Martinique); *amor di neguer* (false love, Netherland Antilles); *amor falso* (false love); *amora falsoe* (false love, Netherland Antilles)

*arhui-arhui*

bass viola strings

*bejuco amarillo* (yellow vine, Dominican Republic); *bejuco de buey* (ox vine, Puerto Rico); *bejuco de mona* (monkey vine, Puerto Rico); *bejuco fideo* (noodle vine, Cuba); *bejucito de amor* (little love vine, Dominican Republic)

*cipó chumbo* (lead vine, Brazil); *cipó dourado* (golden vine, Belém, Brazil)

*corde à violon* (violin strings, Martinique); *cuerda de violin* (violin strings, Puerto Rico, Colombia); *cuerdilla* (little strings, Colombia)

*cuscuta d'Amerique* (American cuscuta, Haiti)

devil's guts; *duivelsnaai-garen* (*duivel*, devil, *snaar*, string, *garen*, thread, Netherland Antilles); *hilu di diabel* (devil's string, Netherland Antilles)

dodder (Jamaica, Puerto Rico); yellow dodder (Virgin Islands)

*enreda cotorra* (parrot catcher, because the birds are easy to catch when they are tangled in the stems, Colombia)

*fideillo* (little noodles, Cuba); *fideitos* (little noodles, Dominican Republic); *fideo* [*fideos*] (noodles, Cuba, Dominican Republic, Puerto Rico, Colombia); *fios de ovos* (egg noodles, Belém, Brazil)

hell weed

*herbe à amitié* (lover's herb, Martinique); *herbe a amourette* (love vine, Martinique)

*hierba mala* (weed [literally bad herb])

*hilo de oro* (cord of gold, Venezuela)

*kanlecay* (*kan*, yellow, *le*, leaf, *kay*, fish; because the scales of the stems remind them of fish scales, Maya, Yucatán)

love bush [vine] (Jamaica, Virgin Islands, Barbados); love weed

*planta de bruja* (sorceress's plant)

*planta sin pie* (plant without a foot [base])

*rejillo* (Colombia)

strangle-weeds (South)

wild vermicelli

yellow love (Virgin Islands)

***Cuscuta compacta*** (compact, referring to the dense inflorescences) (as *C. paradoxa*)

compact cuscuta (a book name; a translation of the Latin)

*hakastahkata* (*hakastah*, vine, *kata*, yellow, Pawnee)

***Cuscuta gronovii*** (for Jan F. Gronovius, 1690–1762)

scaldweed (there are two meanings for “scald” and it is not clear which may be applicable here: perhaps the intent is to indicate that the plant can be used to treat “scalds” or burns from a hot liquid, a meaning in use since about A.D. 1300; the other meaning is “scaly,” in use by the 1530s, and that is not obviously applicable)

***Cuscuta umbellata*** (umbellate, the inflorescences)

*bejuco fideo* (noodle vine, Cuba)

*cipó chumbo* (lead vine, Brazil)

When I worked in Belém, Brazil, I was surprised to find people encouraging *Cuscuta* on their croton (*Codiaeum*) hedges in their front yard gardens. When we asked them about the plants, they told us they were *cabelos de Jesus* (Jesus’s hair). They considered them not only ornamental, but also medicinal. The name seemed to be associated with the Doctrine of Signatures. However, when I looked more closely at the literature, I discovered that an older name was *cabellos de Venus* (Venus’s hair). As both Venus and Jesus are associated with love, albeit different kinds, both are equally appropriate for the plants.

While people derived from Western European temperate regions uniformly regard *Cuscuta* as a pest, that is not true of other cultures. Among the indigenous people of North America, for example, there are records of the Cahuilla, Cherokee, Diegueño, Kawaiisu, Navajo, Paiute, and Pawnee using the plants for food, medicine, cleaning “pads,” and dyes.

Only the Cherokee in the east were found to have used *Cuscuta*. They applied *C. gronovii* as a poultice for bruises (Hamel and Chiltoskey 1975). Farther west the Pawnee used *C. compacta* to predict whether or not their suitors were sincere, and made an orange dye from it (Gilmore 1919). Paiute knew the parasite as “woman without children,” and ate it as a contraceptive (Moerman 1998). Wooton and Standley (1915) and Yanovsky (1936) found that the Navajo have eaten the parched seeds of *C. megalocarpa* for food, and Moerman (1998) said they have used it as an emetic in ceremonies. The Pima do not distinguish species but use generic terms for the plants. Historically they considered them poisonous, and believed that “if a snake sees them take the plant [on which it grows], the snake will get after them” (Curtin 1949). Now, they regard *Cuscuta* more as an agricultural pest (Rea 1997).

Cubans use *C. americana* to treat liver problems and as a laxative (Roig 1945). In the Bahamas, *C. americana* is considered an aphrodisiac and a bath for prickly heat and itching (Morton 1981). In Haiti it is used against jaundice. A decoction is used on sores as an antiseptic; it is considered antibilious, laxative, carminative, and antiparasitic (Liogier 1978). Hocking (1997) considered the plants tonic, astringent, and alterative. It is used with *Tecoma stans* to lower fever in the Virgin Islands. Jamaicans drink a tea for colds, colic, and marasmus in children (Morton 1981). They mix it with *Borreria laevis* and *Zebrina pendula* as an emmenagogue. In Trinidad, a *C. americana* infusion is taken for jaundice, and a decoction is a bath for marasmus. In Yucatán, *C. americana* is used to relieve dyspepsia. In Suriname it is used to stop dysentery and urinary problems.

To treat sores, Cubans use *C. umbellata* as an antiseptic, and they consider it diuretic, tonic, and good for the stomach (Roig 1945). LeCointe (1947) recorded that in the Lower Amazon in Brazil, a powder of the entire plant of *C. umbellata* was applied to cure sores and ulcers. He considered an infusion as astringent, stomachic, diuretic, and good to treat severe diarrhea. It was also gargled to relieve laryngitis. Hocking (1997) listed *C. umbellata* as vulnerary, and noted that the fresh juice had been used against angina and tuberculosis.

Mors et al. (2000) noted that most Brazilians used all *Cuscuta* similarly. They found that they were emollient, anti-inflammatory, stomachic, antidiarrheal, purgative, depurative, diuretic, and antidiarrheal. *Cuscuta* was used in treating throat infections, liver colics, bleeding diarrhea, tuberculosis, wounds, and sores.

Because of their yellow or orange colors, it is not surprising that some have been found to have beta-carotene, alpha-carotene-5, and they also have 6-epoxide, taraxanthin, and lutein (Hsu 1986). Ergoline alkaloids have been reported in some (Mandriale and Dongiorno de Pfrter 1990), but Eckert Eich (personal communication, May 2003) says they are incorrect. The species he and his students have examined do not have ergoline alkaloids. Most members of the Convolvulaceae have calystegines, but they too are absent from *Cuscuta* (Schimming et al. 1998).

### *Cynoglossum*

(From Greek *kynos*, dog, and *glossa*, a tongue, referring to the leaves, which people thought resembled a hound's tongue)

*äsükitä'boe* (stickers, for *C. officinale*, Potawatomi; compare with Cherokee below)

*cinoglossa* (hound's tongue, from Greek, Italian); *cynoglossa* (Spanish); *cynoglosse* (French); *hundetunge* (Norwegian); *Hundszunge* (German); *langue de chien* (French); *teang' a' choin* (Gaelic)

#### *Cynoglossum virginicum* (of Virginia)

dog-bur

hound's tongue

*unistil'unisti* (they stick on, Cherokee)

wild comfrey (comfrey is of obscure etymology; related to Old French *confine*, and Medieval Latin *cumfira*, perhaps related to *confirma*, to make well)

Europeans were well acquainted with hound's tongue when they arrived in the New World, although they had *Cynoglossum officinale* (medicinal). The American species is similar enough that they had no trouble distinguishing it as a new kind of hound's tongue. Culpeper (1653) wrote: "The root is cold, drying and binding, it is useful in catarrhus defluxions upon the lungs, and to temper the sharpness of the blood; and, by consequence, excellent for all kinds of fluxes and hemorrhages."

The Cherokee drank a decoction of root or tops for kidney troubles, and bruised the root with bear grease as an ointment to treat “cancer.” They also drank a decoction of the plant to improve memory and used it in love charms (Mooney 1885–1886). The Cherokee also used it in “Green Corn” medicine, and against itch, particularly itching genitals (Hamel and Chiltoskey 1975, Foster and Duke 1990).

The Old World *C. officinale* contains the potentially cyanogenic alkaloids cynoglosine, consolidine, plus fatty oils, and choline. The alkaloids function as a central nervous system depressant (Foster and Duke 1990, Hocking 1997). Presumably, the American *C. virginicum* also contains those compounds.

### *Cyperus*

(The ancient Greek *kyperos* or *kyperios*, the name of the galingale or sedge)

*Cyperus haspan* (an indigenous name in Sri Lanka for the sedge)

[haspan] flatsedge (“flat,” not angled in this sense, is akin to Swedish *flat* and Dutch *flad*; possibly from Old Aryan *plat*, and related to Greek *platos*)

sedge (from Old English *seíg*, related to Low German *segge*, both probably from the Latin *secare*, to cut; akin to Old Celtic *seska*, Irish *seisg*, Welsh *hesg*, Breton *hesq*)

*sokihatkhakcobâ:bî* [*çokihathaktcobabi*] (opossum [white pig] ear replica, Mikasuki; cognate with *sokhv*, pig, *hvtke*, white, *hvcko*, ear, *vhake*, resembling, Muskogee)

The “galingale” originally was either one of the Zingiberaceae, maybe *Alpinia*, or a sedge, or both. The name “galingale” was imported into Europe by at least A.D. 1000, and probably earlier. The word is thought to have been derived from Middle Eastern and Asiatic languages (Arabic *khalanjan* or *khaulinjan*). Dodoens was one of the first Europeans to record it being a sedge, *Cyperus longus*. A 1578 translation of his Latin reads, “The roote of Cyperus or English galingal is hooted and dry in the third degree.” Subsequently, the name has been applied to several species of *Cyperus*. Not only have people used *Cyperus* medicinally, but they also use the stems for weaving mats and filling pack saddles (Morton 1981).

Although not stated by Sturtevant (1955), the Mikasuki name suggests association with the “Opossum Sickness” (*sokihátkiinoka:cí:cihci*). While his collaborators had a name for the sedge, they revealed no uses.

### *Cyrilla*

(Linnaeus named these shrubs and small trees in honor of Domenico Cirillo, 1734–1799, a professor of medicine at Naples)

*Cyrilla racemiflora*. From Sargent  
1905.

*Cyrilla racemiflora* (having flowers in racemes) (= *C. antillana*)

*barilla* (maybe from Taino, *baria*, the forest tree *Cordia gerascanthus*, Cuba)

beet wood [beetwood] (because bark and heart-wood are red as beets, Adams 1972, Jamaica)

bloodwood (because bark and heartwood are red, Jamaica)

*bois couché* (bed-wood, Guadeloupe)

burn-wood (West Indies)

*clavellina* (little carnation, Cuba)

*Colorado* (red one, Puerto Rico); *palo Colorado* (red tree, Puerto Rico, Dominican Republic)

[American, swamp] *cyrilla* (USA, Puerto Rico)

*granado* (the same name is given to the pomegranate, *Punica granatum*, Dominican Republic)

he-huckleberry (because these shrubs never produce fleshy berries, people have concluded they are “males”; the comparison to huckleberry is not as far-fetched as it may appear—they are related to *Vaccinium*)

iron-wood (West Indies)

[southern] leather-wood [leatherwood] (“leatherwood” in use since 1760, but originally applied to *Dirca*, which see)

*llorona* (crying woman, Cuba)

*olivier montagne* (mountain olive tree, Guadeloupe)

*piojillo* [*piojito*] (little louse, Venezuela)

*sabina macho* (male juniper, Dominican Republic)

[black, red, white] *titi* [*ti-ti*] (etymology uncertain, maybe from “tie.”)

In the United States, this name has been given to the buckwheat tree or black titi, *Cliftonia monophylla*, Cyrillaceae, or to leatherwood, red titit, or white titi, *Cyrilla racemiflora*, both applied by Chapman’s *Flora of the Southeastern United States* of 1860; also to sourwood, *Oxydendron arboreum* by Small’s *Flora of the Southeastern United States* of 1903. The ultimate origin is unknown in the United States. However, the word has been derived from Tupí, as the name of monkeys in the genus *Callithrix* from 1832; and from Maori, the name in New Zealand for the diving petrel, *Pelicanoides* or *Halodroma urinatrix*. Probably the southeastern U.S. application is yet another derivation, from the use of the strong inner bark of some species for tying, or from the fact that the tree “ties” up everything in its thickets. The local use in northern Florida

implies that it came about because of the difficulty in passing through the vegetation consisting of these plants, hence local names such as “Titi Hell”; applied to members of Cyrillaceae by Williams [1837] 1962. See also *Dalbergia*.)

*warimiri* (Arawak, Guyana, Suriname)

*yanilla* (maybe from Taino, *baria*, the forest tree *Cordia gerascanthus*; or perhaps diminutive of Taino *yana*, the buttonwood, *Conocarpus erectus*, Cuba)

In the 1970s, I had a grant to study vegetation in the Fakahatchee Strand State Preserve in Collier County. The first person I hired to work for me was an unlikely field botanist, Julie Jones. She had terrible vision (“I am legally blind”), had spent her college years working in a laboratory, and knew nothing about wild plants. However, she was incredibly enthusiastic and turned out to be one of the best field assistants I ever worked with. She went on to become one of the first two women to be hired by the Florida Game and Fresh Water Fish Commission, and attributes passing the field exam to working for me.

The final exam for the commission recruits was to navigate through wild country they had never seen in the Florida Panhandle at night. They were given a compass, a small flashlight, and a topographic map. Those who made it to the rendezvous point the next morning passed the exam. Julie said it was a breeze after working with me in the thickets and unsurveyed wilds of southern Florida. There was one problem—she got diverted by a titi swamp, or as they knew it in the Tallahassee area, “Titi Hell.” In spite of the “Titi Hell,” Julie became the first female lieutenant colonel in Florida’s history, and continues to be promoted.

The “Titi Hell” that temporarily stumped Julie was composed of both kinds of titi, *Cyrilla* and *Cliftonia*. No doubt, Alexander Garden, who collected the plants Linnaeus used to name *Cyrilla*, had fewer problems gathering them.

Alexander Garden (1730–1791) was a physician and amateur botanist who lived in Charleston, South Carolina. Linnaeus named the cultivated *Gardenia* in his honor, making his name famous in botanical and horticultural circles, although most of us had no idea who he was.

Between the publication of Linnaeus’s *Species Plantarum* in 1753 and the appearance of his *Mantissa Plantarum* in 1767, Garden had collected and sent him a new kind of plant from the Carolinas. According to the label in Linnaeus’s herbarium, he collected the small tree “*in Carolinae pinetis humentibus*” (in moist Carolina pinewoods). In 1767, Linnaeus called the plants *C. racemiflora*; at the same time, he created a new genus and species.

After 74 years passed, the Austrian director of the botanical garden in Vienna, Stephen F.L. Endlicher (1804–1849), published his book called *Enchiridion botanicum* in 1841. In that volume, he created the family Cyrillaceae, based on the genus *Cyrilla*. Although there have been changes since, the family is now considered to contain three genera—(*Cyrilla* (monotypic), *Cliftonia* (monotypic, southeastern USA), *Purdiaea* (12 spp. in tropical America, especially Cuba)—and 14 species (Brummitt 1992, Stevens et al. 2001). Those families are part of “core Ericales” along with Actinidiaceae, Clethraceae, Ericaceae, and Sarraceniaceae (Judd et al. 2002).

In Puerto Rico, *Cyrilla* wood is seldom used except for fuel, because it warps badly during seasoning. In Cuba and Hispaniola, the handsomely colored wood has been made into furniture (Little and Wadsworth 1964, Liogier 1978). The spongy bark at the base of the trunk is absorbent, pliable, and astringent, and has been used as a styptic to stop bleeding in several parts of its range (Liogier 1978). Porcher (1863) wrote: "It has been used with advantage as a substitute for agaric and other styptics. I learn that it is much confided in for this purpose by those living in Darlington district, South Carolina. When rubbed on the hand, it produces a sensation similar to that produced by the application of an astringent fluid. It has also been applied to ulcers when the indication is to cicatrize them. This plant merits further attention."

One of the active compounds in its function as a styptic is tannin. Cronquist (1981) indicated that the plants are high in tannins, and that is surely one of the compounds involved in their red color. Although no records have been found, surely indigenous people and settlers used these tannins in curing animal skins. That application is suggested by the name "leatherwood," as this tree does not have bark resembling that of *Dirca* (which see).

Thomas (1960) investigated variation in the species and concluded that clonal reproduction is correlated with a high incidence of seedless parthenocarpy in populations where self-pollination is high. Because sexual reproduction is low, these factors have combined to create a pattern in which morphologically distinct populations occupy different habitats.

### *Cyrtopodium*

(Greek *kyrtos*, curved, convex, and *podium*, a small foot, in reference to the curved foot of the column of the flower)

***Cyrtopodium punctatum*** (spotted, referring to the flowers)

*abejitas* (little bees, Dominican Republic)

*cañuela* (little cane, Cuba, Hispaniola, Puerto Rico); *canniette* (Haiti);

*canuyele* (Haiti)

*cebolleta grande* (big onion, Venezuela)

cow-horn orchid (the pseudobulbs resemble horns to some)

*orchidea de elote* (*elote* is an unripe ear of corn, Sonora)

*piñuela* (little pine, Puerto Rico)

Linnaeus described these epiphytic orchids in 1759 as *Epidendrum punctatum*. Then, in 1813, when Robert Browne studied plants cultivated at Kew Gardens near London, he created *Cyrtopodium*. In 1833, John Lindley (1799–1865), also in London, moved the Linnaean species into Browne's genus to create the modern name. There are now 30 species in this American genus (Mabberley 1997).

A decoction of the pseudobulbs is used as a pectoral, against cough, bronchitis, and asthma (Roig 1945). The decoction is also used on skin infections, broken bones, and bruises in Cuba and Hispaniola (Liogier 1974). A mucilaginous pulp from the bulbs was used as glue by the indigenous people and early settlers (Luer 1972).

## D

### *Dalbergia*

(Named by Linnaeus f. for Swedish planter Carl Gustav Dahlberg (fl. 1753–1775), who collected for Linnaeus and who was a mercenary in Suriname; also for his brother Nils E. Dahlberg, 1730–1820, who was a Swedish court botanist-physician)

*Dalbergia ecastophyllum*. Drawn by  
P.N.Honychurch.

*Dalbergia ecastophyllum* (Greek *ek*, out, *aster*, star, *phyllum*, leaf, in reference to the unifoliate leaves)

*akarerowoi* [*akareroai*] (Carib, Suriname)

*bejuco de peseta* (coin vine, Dominican Republic); coin-vine (Florida)

*bejuco serná* (maybe *serná* is a variant of *sarna*, a contagious skin disease, Cuba)

*chapero* (from *chapa*, leaf or sheet, Belize)

dogwood (Belize)

hoop wood (used for barrel hoops, Barbados)

*liane à barriques* (barrel vine, Guadeloupe, Martinique); *liane à barriques bord-de-mer* (seaside barrel vine, Guadeloupe, Martinique); *liane a clous* (boil vine, *clou*, nail or boil, Haiti)

*maraimaray* [*marai-marai*, *maray-maray*] (Puerto Rico, Venezuela); *maramare blanco* (*mare* is a type of reed used for flutes, but this name probably came from an indigenous word; maybe Arawakan, Venezuela)

*palo de pollo* (chicken tree, Puerto Rico)

*péndola* (dangler, Cuba)

ti-ti (Bahamas; cf. *Cyrilla* for etymology)

*z'herbe a clous* (boil herb, *clou*, nail or boil, Haiti)

*Dalbergia* was named in 1782, not by Linnaeus, but by his son. In his *Supplementum Plantarum*, an addendum to his father's *Species Plantarum*, the younger Linnaeus created the name for an Old World species. In 1894, German botanist Paul Hermann Taubert (1862–1897) moved a species the elder Linnaeus had named to create *Dalbergia ecastophyllum*. Now there are 100 tropical trees and lianas in the genus, in both the Americas and the Old World (Mabberley 1997). Mostly, the genus is known for providing beautiful and useful wood, but there are other applications.

A decoction of coin-vine is taken as a diuretic, and the sap extracted from the young leaves and branches taken a spoonful per day is an emetic-cathartic (Roig 1945). The bark from the trunk and the seeds are vermicidal and considered poisonous by some.

### *Daucus*

(From Greek *daukos*, *daukon*, sweet, carrot; Latin *daucus*; one of the classical names)

*carota* (Italian); *carotte* (French); carrot (in use by 1533; from French *carotte*, based on Latin *carota*, an adaptation of Greek *karoton*; Dioscorides, A.D. 40–80, called *carota* the *pastinaca silvestris*)

*cenoura* (from Arabic, Portuguese); *zanahoria* (spelled *çanahoria* in 1557, from Arabic *isfanaria* or *sannaria*, Spanish)

*curran fiadhain* (wild carrot, Gaelic)

*gallinacci* (literally little yellow one, but probably derived from Latin *Gallicam*, from France, Italian)

*Gelbe Rübe* (yellow carrot; rendered *Geelrüben* in 1542, German); *gulrot* (*gul*, yellow, *rot*, root, Norwegian)

*Möhre* (German)

*pastinaca* (from Latin *pastino*, dig ground in preparation for planting, and *-aceus*, pertaining to; used by Pliny, A.D. 23–79, for the wild carrot; in use by Fuchs 1542)

*peen* (in use by 1549, Dutch)

Queen Anne's lace (Queen Anne was the ruler of Britain from 1702 to 1712; why this common name appeared in the 1890s is unexplained)

*staphylinos* (classical Greek referring to a carrot or parsnip; in use by Fuchs 1542)

*Daucus pusillus* (very small)

American [wild] carrot

rattlesnake weed

*zanahoria silvestre* (wild carrot, Sonora)

Classical Mediterranean taxonomy was not the same as that used today. The Greeks called the root of the wild carrot *staphylinos*, and they cooked and ate them although they were rarely larger than a finger (Baumann 1993). Dioscorides (fl. A.D. 40–80) recorded that people also mashed the leaves with honey to clean ulcers. In Spain and Portugal, the Arabic influence was so strong that the plants became *cenoura* (Portuguese) and

*zanahoria* (Spanish). The Romans called the same plants either *carota* or *pastinaca*, apparently reserving the latter name for those cultivated.

As late as the 1500s, the carrot was known in French as *carota* (by 1536) and *pastenade* (by 1561), and in Italian as *carota* (by 1561) and *pastinaca* (by 1597). By contrast, the parsnip (in English by 1398, from *pastinaca*) was either *siser* or *pastinaca* (Latin), *cheruy* (French), *rape gialle* (French turnip, Italian), or *chiriuiia* (Spanish). Leonard Fuchs called the parsnip *sisaro* in 1542.

That variety of names resulted in those used today in the regions formerly under the rule of the Roman Empire. For the carrot, Charles de l'Ecluse in 1576 and Joseph Pitton de Tournefort in 1700 preferred *Daucus*, while Gaspar Bauhin (1623) used *Pastinaca*. Finally, in 1753, Linnaeus used *Daucus* for the technical name of the carrot, and the parsnip became *Pastinaca*.

When Europeans arrived in the New World, they found a small, annual, wild carrot, *D. pusillus*, already there. That species occurs naturally from Florida to California, and north to South Carolina, Missouri, Kansas, and British Columbia (Fernald 1950, Steyermark 1963, Barkley 1986).

Unfortunately, for unraveling the uses of native plants, the Old World carrot (*D. carota*) was introduced soon after Europeans arrived. It escaped almost immediately, and became known throughout the eastern states as Queen Anne's lace.

The problem with compiling a list of uses of carrots is separating the native from the alien species. As an example, editor Richard Drinnon identified the "Beaver root" in Hunter ([1823] 1973) as *D. carota*. However, there is no real evidence that the species was wild in the region of western Missouri and adjacent states occupied by the Osage and Kansas at that time. Carrots were in Virginia between 1609 and 1648, in Massachusetts by 1629, and in New York by 1779 (Hedrick 1919).

Hunter said the Osage name was *sha-ba-wa-nembra* (beavers eat it; *zha'-be*, beaver, *wa-non-bthe*, to eat), and that it "very much resembles the common garden carrot, in size and appearance, but in taste it is disagreeably bitter." Steyermark (1963), however, indicated that the roots of wild carrots are sweet and good. Fernald et al. (1958) concurred and thought that the roots raised from the seeds of wild plants were "remarkably sweet." The identity of the plant discussed by Hunter cannot be confirmed, but it might have been *D. pusillus*.

Only among the western tribes is there evidence that the native carrot was used. Yanovsky (1936) said the Nez Perce and Navajo ate the roots, boiled or raw. Moerman (1998) added the Costanoan, Clallam, Cowichan, Mendocino, Miwok, Navajo, Saanich, and Salish. These people used it to clean the blood, to stop itching, to treat fevers and snakebite, and as a good-luck charm. Hocking (1997) indicated that the native *D. pusillus* was used to treat infections and rattlesnake bites, and to promote wound healing.

Moerman (1998) also recorded that the roots were eaten. How much there would be to eat on an annual plant is problematical, and there was confusion with the introduced Old World species. It is pertinent that Hodgson (2001) does not include *D. pusillus* among the edible plants of the Sonoran Desert.

The record on *D. pusillus* looks like one of a native species being supplanted by one introduced from the Old World, which was a more easily obtained food plant and, perhaps, a more effective medicine. Because of the lack of properly documented records, that view remains open to interpretation.

*Descurainia*

(Named for the French pharmacist François Descourain, 1658–1740, a friend of the French botanists Antoine and Bernard de Jussieu)

*Besenrauke* (*Besen*, broom, *Rauke*, mustard, German; *Rauke* is from Latin *eruca*, now the genus *Eruca*)

flixweed (variation of “flux-weed,” alluding to a use to control diarrhea, English)

*hundesennep* (hound’s late turnip, Norwegian)

*sagesse* (French)

*sisymbre* (based on similarity to *Sisyrimbium*, another mustard, French)

*Sophienkraut* (sophie herb; *Sophia* was an old generic name for some mustard, now *Descurainia sophia*, German)

tansy mustard (“tansy” is taken from Medieval Latin *athanasia* and Greek *athanasia*, immortality; akin to “everlasting” or *immortelle* because of the long-lasting flowers; now *Tanacetum*)

***Descurainia pinnata*.** a. Habit, b. Enlarged cauline leaf. c. Flower, d. Silique. e. Seeds. *Drawn by Regina O. Hughes.* From Reed 1971.

*vulgare*, Asteraceae; tansy-mustard was in use by 1856 when Asa Gray applied it to *Sisyrinchium*)

***Descurainia pinnata*** (pinnate, the leaf lobing) *shuu'uvad* [*rú-u-what*, *show-ou-wat*] (maybe *such'iavik*, recorded by Curtin 1949, is a faulty transcription, Pima, Arizona); *shuu'uwad* (Tohono O'odham, Arizona); *shu'awat* (Pima Bajo, Sonora)  
[pinnate, western, yellow] tansy mustard

I spent the first 29 years of my life living around *D. pinnata* without knowing what it was. Then, when I went to Florida, I was south of tansy-mustard's range. It was not until I came to Arizona in 2001 that I learned to identify the plants. In my yard, and the surrounding desert, the plants came up in thick patches on disturbed sites after the winter rains in 2002. I could easily understand why people, at least those in the West, considered it a major seasonal food source.

Tansy mustard is a species that grows from Florida to California, and from Quebec to British Columbia (Fernald 1950, Barkley 1986, Welsh 1987). It also grows in Chihuahua, Sinaloa, and Sonora, Mexico (Wiggins 1980, Felger 2000, Hodgson 2001). People throughout the western part of its range ate the seeds, and probably those in the eastern states did during the old Eastern Agricultural Complex (Hudson 1976). As many of the western tribes remained gatherers, they may have retained more of the uses for small seeds that were lost in the East when maize, beans, and squash were introduced.

*Descurainia* was used by the Hohokam of Arizona. Indeed, some think it was possibly cultivated, and seeds have been recovered from pottery in two archaeological sites (Hodgson 2001). Among the historic people, the plants have been recorded as used among the Atsugewi, Cahuilla, Cocopa, Gosiute, Hopi, Kawaiisu, Keres, Maricopa, Mojave, Navajo, Paiute, Tohono O'odham (Papago), Akimel O'odham (Pima), and Quechan (Moerman 1998, Hodgson 2001).

Maricopa and Quechan baked the young growth as greens in a pit lined with hot stones. They piled alternating layers of greens and hot stones, covering the top with earth. After about 30 minutes, they ate the greens or dried and stored them (Hodgson 2001). Possibly other people ate them similarly, but no records of this have been found.

Mostly, people ate the seeds. Atsugewi, Cahuilla, Cocopa, Gosiute, Hopi, Kawaiisu, Keres, Maricopa, Mojave, Navajo, Paiute, Tohono O'odham, and Akimel O'odham are among the people known to have consumed them. This was still the most commonly used seed crop by some Tohono O'odham in the 1930s (Hodgson 2001). However, soon afterward, they were lost from their diet, probably sometime before 1945 (Rea 1997). Rea (1997) speculated that people stopped eating them because they objected to their mucilaginous nature.

There were different preparations, but the one among the Akimel O'odham and Tohono O'odham is perhaps typical of southern tribes. The plants were picked when the fruits were ripe. Then the minute seeds were shaken into baskets. The seeds were then roasted, mixed with water, and eaten like *atole* (Curtin 1949). Historically the Akimel O'odham also made a cold drink of raw seeds. Seed pods were gathered in a basket, the seeds extracted, winnowed, and then ground. The flour was added to cold water with

sugar for a cold drink. “The Papago use it much in the summer, saying it cools them off” (Rea 1997).

The Pima also used the tiny seeds to extract foreign objects from the eye (Rea 1997). One seed is put in the eye and it brings out the foreign object. Seeds were sold in great quantity near the villages of Altar and Guaymas, Sonora in 1900 (Hodgson 2001). More recent people living in the Guasabas-Granados area of northeastern Sonora used *pamita cimarrón* (unknown *Descurainia* sp.) as a stomach medicine. Similarly, the Paipai in Baja California used *pamita* (*D. pinnata*) as a remedy for *empacho* (indigestion), stomachache, and vomiting (Ford 1975). Mucilage around seeds may coat the digestive system and slow digestion, thereby helping control diabetes (Hodgson 2001). Seeds were used for stomach ailments by the Cahuilla and for sores by the Pima (Moerman 1998). A poultice of the herbage was used for toothache by the Navajo, and the Utes used the plants in an unspecified medicine. Hocking (1997) noted that the seeds were put in sugared water for liver diseases, but does not say which people did so.

The Hopi used the plant mixed with dark iron pigments as a dye. They used the pigment to decorate pottery (Moerman 1998).

Kearney and Peebles (1942) wrote that the herbs, “although avoided while the plants are green, are relished, especially by horses, when the buds are ripe.” In spite of that, Diggs et al. (1999) reported that the herbs were poisonous to livestock, producing symptoms similar to selenium poisoning; animals become blind, wander aimlessly, and lose the ability to swallow; the sickness is called the “blind staggers” or “paralyzed tongue.”

### *Desmanthus*

(From Greek *desme*, a bundle, and *anthos*, flower, presumably from the flowers clustered in heads)

*Desmanthus illinoiensis* (from Illinois) *atikatsatsiks* [*ati(t)ka tsatsiks*] (*atit*, bean, *tsatsiks*, spider, *ka*, inside, Pawnee)

[Illinois, prairie] bundle-flower [bundleflower] (bundle-flower is a translation of the genus)

*kitsitsaris* (*kits*, plant, *tsitsaris*, bad, Pawnee)

*pezhe gasatho* (*pezhe*, plant, *gasatho*, rattle, Omaha-Ponca)

prairie-mimosa (André Michaux, who originally described the species, put it in the genus *Mimosa*)

prickle-weed (from confusion with *Mimosa*?)

spider bean

*Desmanthus* is a small genus of 24 species mostly confined to the warm parts of the Americas (Mabberley 1997). The plants look markedly like *Mimosa*, but *Desmanthus* is always unarmed and has sessile fruits. *Mimosa* is often armed and has stalked legumes. *Desmanthus* is usually confined to prairie regions, occurring in the Great Plains, in the desert grasslands of southern Arizona, and similar areas. *Desmanthus illinoiensis* is

centered in the southern Great Plains, with extensions to the east into Florida and west into Texas (Diggs et al. 1999).

The common name “prickle-weed” poses a conundrum. These plants lack the prickles or spines of *Mimosa* and related genera. So why do they have the common name? No help is forthcoming from the OED (1971) as it does not list the name. Asa Gray, sometimes the first to record such names, calls them “desmanthus” in his *Lessons in Botany* published in 1875. As usual, Chapman (1897) provides no common name. Gilmore (1919) said they were “spider-bean,” taking his cue from the Pawnee. John K. Small (1933) called them “prickle-weed.” Could the name be as late as the 1930s? Or did it result from confusion with *Mimosa*?

All of the records of people using these plants medicinally are in the western states, including the Keres, Omaha, Paiute, Pawnee, and Ponca (Moerman 1998). Along the Missouri River area, Gilmore (1919) was among the first to record their place. The Omaha-Ponca and Pawnee used the leaves to treat itch. Seeds were used by the Paiute to treat conjunctivitis (Moerman 1998). The Keres had a name for the plants, but no use was given.

Omaha-Ponca boys made toy rattles from pods (Gilmore 1919). That use is reflected in their name for the plants. The Meskwaki and Potawatomi used the root juice to lure animals into traps (Smith 1933, King 1984).

Seeds are reportedly high in protein (Foster and Duke 1990), but there seem to be records of only wild animals eating them. The Mayo of Sonora noted that their quail are fond of the seeds and they make use of that to hunt these birds (Yetman and Van Devender 2002). Although Martin et al. (1951) did not list the genus as bird food in the United States, it seems probable that the seeds are used in Florida.

### *Desmodium*

(Desvaux used the Greek word *desmos*, a bond or chain, in reference to the jointed fruit pod, a loment)

***Desmodium incanum*** (ash-colored with pubescence) (= *D. supinum*, *D. canum*)

*amor de campo* (wild love, Cuba?); *amor seco* (dry love, Cuba, Dominican Republic, Colombia)

bee bur [bush]

beggar's ticks (USA)

\**bisbiská*? (Paya, Honduras)

*bissalun̄ko* (*bissa*, blackberry, *lun̄ko*, grunt, like a hog, Choctaw)

*cadillo* (usually an umbel, Colombia)

*chausiya* [*ischautzia*] (Totonac, Veracruz)

chickweed (Cayman Islands)

*collant* (sticky, Guadeloupe, Martinique)

common tick-trefoil (Bahamas); *grand trèfle* (big clover, Guadeloupe, Martinique), tick-[clover, trefoil] (USA); *trèfle savane* (savanna clover, Guadeloupe, Martinique)

cousin [kuzen] (Bahamas); *cousin grand-savane* (big-savanna cousin, Guadeloupe, Martinique); *cousin trois sous* (cousin three times, Haiti)  
*empanadilla* (little turn-over, referring to the resemblance of the shape of the laments to the bakery treat, the *empanada* or turn-over, Cuba)  
 fever weed (Bahamas, Trinidad)  
 iron vine (Barbados)  
*kowike entvlako* (*kowike*, quail, *em*, its, *tvlako*, beans, Muskogee)  
 mañ back (Belize?); strong back (Belize)  
*mozote* (maybe from *mozta*, tomorrow, Central America)  
 peanut (Bahamas)  
*pega pega* (sticker-sticker, Mexico, Costa Rica, Colombia); *pega ropa* (clothes sticker, Mexico)  
*sá-rá [s-r]* (maybe a combination of Maya and Spanish or English; *sa*, cornmeal drink or *atole*, *ra*, there are no words beginning with “r” in Maya, Belize)  
 stick-tights (USA)  
*‘stvlokpuce* (*vlokpictv*, to stick on, Creek)  
 sweetheart (Barbados)  
*tofō:ma* (Creek); *tofoome [tofō:mi]* (Mikasuki)  
*tortilla de ratón* (mouse’s bread, Mexico)  
 wild ground-nut [wild granite] (Bahamas)  
 wild pinder  
*zarzabacoa* (a variant of *guasabacoa*, a *Desmodium*, Taino, Puerto Rico)

***Desmodium paniculatum*** (tufted, the flower clusters)  
*l’herbe à collet rouge* (sticky red herb, Houma)  
 panicked-leaf tick-trefoil (a book name)

***Desmodium rotundifolium*** (round-leaved)  
 dollar leaf (USA)  
 flux vine (USA)  
 prostrate tick-trefoil [prostrate ticktrefoil]

The French professor in Angers, Nicaise Auguste Desvaux (1784–1856), created the genus *Desmodium* in 1813. Now, the genus contains 450 species, most of them in tropical regions (Mabberley 1997). In lifeform they range from small herbs with pesky fruits (laments) that cling to trousers, socks, and other articles of clothing to trees that produce timber. Several are used in medicines.

As the name “flux vine” suggests, *D. rotundifolium* is known for stopping dysentery. It has been used for medicine near Tallahassee and in nearby Mississippi (Hocking 1997). Perhaps this is the same species that the Alabama used in that region for bad colds and lung problems (Taylor 1940). In Louisiana, the Houma used *D. paniculatum* for “one who suffers from weakness and cramps,” by soaking the broken roots in whiskey and having the sick person drink it (Speck 1941).

Although Snow and Stans (2001) suggested their plant might be *D. lineatum* (sand tick-trefoil [sand ticktrefoil]), the photo they included is of *D. incanum*. Presumably, they were dealing with only a single species.

The many names applied to *D. incanum* reflect not only use by humans, but also their irritation at its apparent constant presence. The sticky loment adheres to virtually everything, making it an easily dispersed herb. However, those who raise livestock acknowledge its value as fodder and as food for wild animals. Howard's (1984) Seminole informant recognized that quail feed on the fruits.

Alice Snow knew that '*stvlokpuce*' was used "for lots of different things" (Snow and Stans 2001). '*Stvlokpuce*' is used for treating alcoholics and for pregnant women near delivery. The Seminoles also still use it when "you don't feel like eating and throw up" ("Snake Sickness") (Snow and Stans 2001).

Leon and Alain (1974) record that a decoction of the root is good for dysentery and liver problems; also diuretic and good to settle the stomach. Cubans consider it an excellent hemostat, and it was used in the wars for independence in the hospitals to heal wounds. It also has been used on that island to stop internal bleeding (Roig 1945).

In the Bahamas and Trinidad, herbal teas are taken for heat, urinary problems, and fever. The herb is boiled to make a tea for excessive or painful menstruation or with salt to lessen pain after parturition (Ayensu 1981). The Jamaicans drink a decoction to alleviate colds (Morton 1981). An infusion has been used in Guatemala and Honduras to treat gonorrhea (Hocking 1997). It is a medicinal plant in Belize (Balick et al. 2000).

### *Dicliptera*

(Named by A.L.Jussieu from Greek *diklis*, double-folding, and *pteron*, wing, referring to the two-winged capsule)

***Dicliptera sexangularis*.** a. Leafy branch imposed on part of inflorescence, b. Flower, side view. c. Flower longitudinally dissected, d. Ovary and

lower part of style, e. Floral diagram, f.  
Fruit. *Drawn by Priscilla Fawcett.*  
From Correll and Correll 1982.

***Dicliptera sexangularis*** (six-angled) (= *D. assurgens*)  
*amor seco* (dry love, the name may reflect confusion with *Desmodium*,  
which see)

foldwing (Florida)

*nimiz* (*nii*, nose, *miis*, cat, Maya, Yucatan)

*penasmiento* (the thinker)

*tinta montañas* (wild ink)

*uxkwe' ts'ohool* (old lady herb, Huastec, San Luis Potosí)

*wits pay a'* (flower *paya'* Huastec, San Luis Potosí)

*yerba fluxion* (flux [diarrhea] herb)

In 1696, Leonard Plukenet called a plant he found in Jamaica *Euphrasia*, *affines majori folio* (similar to *Euphrasia* but with larger leaves). Linnaeus ([1753] 1957) called it *Justicia sexangularis*. Both of those genera are other members of the family, but these herbs did not actually belong to either one. Then, in 1807, Jussieu moved Linnaeus's species to create *Dicliptera sexangularis*. Today, there are 150 species in the genus (Mabberley 1997).

In Yucatan, the plant is a remedy for asthma (Morton 1981). The Huastec of San Luis Potosí use the herb to stop hemorrhage, and to quiet restless babies (Alcorn 1984); it is used to treat eye problems in Veracruz (Vásquez and Jácome 1997). They also bundle the branches to make brooms.

### ***Diodia***

(From Greek *diodos*, a thoroughfare, because it often grows by waysides; Quattrocchi thought possibly from *dis*, twice, and *edos*, *edios*, form or kind, referring to the calyx)

***Diodia teres*.** a. Habit, b. Section of stem with leaves and young fruits, c. Seed. From Buchholtz 1968.

***Diodia teres*** (round)

buttonweed [rough] (in use by 1878, perhaps first for a European Composite)

poor joe [pó jó] (the South, from Arizona to the Carolinas)

poor weed; poor-land weed (considered an indicator of almost sterile soils)

*Diodia* is a genus of about 30 species in tropical and warm parts of the Americas and Africa (Mabberley 1997). Linnaeus ([1753] 1957) knew the single species *Diodia virginiana* from Jan Gronovius's *Flora Virginica* and from cultivation at the *Hortus Cliffortianus*. *Diodia teres* was not described until 1788 when Thomas Walter named it in his *Flora Caroliniana*.

This variable species ranges from Florida to Arizona and southern California, and north to New York, Pennsylvania, Ohio, Illinois, and Missouri. In Mexico it grows in Baja California Sur, Sinaloa, and Sonora. Hocking (1997) says that it has been used in domestic medicine, but gives no further details.

*Dioscorea*

(Linnaeus dedicated the genus to the Greek naturalist Dioscorides, fl. A.D. 40–80, a native of Anazarba in Sicily)

*Dioscorea villosa*. From Britton and Brown 1896.

*Dioscorea villosa* (soft-hairy)

China root (possible confusion with *Smilax*, which see)

colic-root (a name also given to *Alettris*, which see)

devil's bones

rheumatism root

[Atlantic, wild] yam [root] ("yam" from *ñamé*, an African word; the OED 1971 says that the word appeared in Spanish as *igname* in 1557, but Columbus spelled it *niames* with other variants in his journal of 1492; see Jane and Skelton 1960, Sauer 1969; rendered in Portuguese *inhame* by 1567, in French *igname* by 1575, and in English as "yam" by 1589)

Linnaeus ([1753] 1957) recognized eight species of *Dioscorea* when he accepted the genus as proposed in 1703 by Charles Plumier. All that Linnaeus had seen were from India except *D. villosa*, which came from Virginia and Florida. Now the genus contains about 850 species, mostly in the tropics, although one reaches Europe (Mabberley 1997).

The wild yam was not listed officially in the National Formulary as medicinal until 1916, and it remained there until 1942 with recommendations for use as a diaphoretic and expectorant (Vogel 1970). Long before that "official" acceptance, the Meskwaki of Iowa used it to relieve labor pains (Vogel 1970). While there is considerable history of the Maya and Aztecs using their species of *Dioscorea*, there is scant mention of the North American plants among indigenous groups.

Black slaves in the southeastern United States possibly learned to use these plants from the indigenous people, but they surely also knew uses of their own African species and made adjustments. They used *Dioscorea* to treat colic and to relieve rheumatism (Vogel 1970). During the Civil War, Porcher (1863) wrote: "The decoction of the

root...is eminently beneficial in bilious colic: one ounce is added to one pint of water, and half of this is taken at a dose...acts with great promptitude, and... Dr. Neville places much reliance on the tincture as an expectorant; it is likewise diaphoretic, and in large doses emetic.” In South Carolina, Morton (1974) found people mixing it with *Asclepias tuberosa* as a remedy for flatulence and indigestion and with *Aletris farinosa* to treat a prolapsed uterus.

Tubers of *D. villosa*, like others in the genus, contain steroid saponins and resins (Hocking 1997). The most famous steroidal saponin is diosgenin, used in the manufacture of progesterone and other steroid drugs (Lewis and Elvin-Lewis 1977, Foster and Duke 1990). Although originally extracted from plants, diosgenin is now completely synthetic, but continues to be used in oral contraceptives, cortisone, progesterone, and other steroids (Swerdlow 2000). *Dioscorea villosa* is also a source of synthetic DHEA, a hormone that inhibits the production of excess fatty acids and cholesterol (Swerdlow 2000).

### *Diospyros*

(Named by Linnaeus for the Greek deity Zeus, *dios*, divine or god, *pyros*, grain; *diospyron* was the ancient name used by Theophrastus, 372–287 B.C., for the fruit of the nettle tree, *Celtis australis*)

***Diospyros virginiana*** (from Virginia)

*axka*’ (Bilox)

*bitko* (Alabama); [*bitkó cobá bitkó* domesticated; *bitkófihna*, wild, literally “real”], Koasati)

*çta-in’-ge* (Osage)

date-plum (USA); *Dattelpflaume* (date-plum,

***Diospyros virginiana***. From Sargent  
1905.

German); winter-plum (Texas)

*edre*’ (Catawba)

*guajacana* (Catesby 1734–1747 followed Plukenet from 1696 in using an old Italian name for *Diospyros lotus*)

Jove’s-fruit (Texas)

*kafi* (Choctaw; compare with *otkofi* and *ukov*)

*mespila* [Latin *mespilorum*] (LeMoyne [1564–1565] in Florida and then Harriot [[1590] 1972] at Roanoke, Virginia, compared them with European medlars, *Mespilus*)

*olkofi* [*o rkofi*, *o (th)koofe*, *olkofi*] (Mikasuki); *ongouffé* [*ougoufle*] (French spelling of Choctaw name *ukov*, from 1777); *onkof* [*inkof*] (Chickasaw); *ukov* [*unkof*] (Choctaw)

*passi:min* [*pessimin*, *pichamins*, *pushemins*, *putcha mins*] (Strachey wrote the Powhatan words *pessemmins*, *pichamins*, and *pusheminas* in [1612] 1953; he added, “plum very delicious when it is ripe”; Capt. John Smith wrote that it was a “fruit like a medlar...red when it is ripe ...delicious as an apricot.” Powhatan, Virginia); persimmon [*putchamins* *piakamine*, *pessimmon*, ‘*simmons*] (akin to *pasiminan*, dried seed, Cree, *pakimin*, broken seed, crushed fruit, Nipissing, *pakiminasigan*, preserves, Nipissing, *pashkiminassigan*, preserves, sweetmeats, *pasimen*, Delaware, Ojibwa, *piakemen*, cranberry, Menomini, *piakimina*, Illinois name recorded by La Salle in 1682, *piakimini*, Miami, *pokmlnesln*, cranberry, Potawatomi); *phishimons* (Catesby 1734–1747); *piaquiminia* (recorded by Henri Joutel in 1687 among the “Arkansas” [Quapaw]. Presumably, he used the Illinois name); *pishamia* (Plukenet’s 1696 Latin rendering of the Algonquian name, Virginia. Siebert 1975 considered the root word to be */\*pehs-*, a peel or husk, and noted the cognates */piss-* in Ojibwa, */peʔs-ʃ* in Shawnee, and */pehs-* in Penobscot); *plaquemine* (European French); *pliaquemine* (colonial version of indigenous name in use by 1751; retained in French-speaking regions of Louisiana and Missouri)

possum apple (a Cracker name, Florida); possumwood (Texas)

*sah lee* [*sa’-l(i)*, *salt*, *sa-thl(i)*] (Cherokee)

*sata* (simple term, Creek); *svtv* [*svt’v*] (Muskogee; there is a creek called Cetaehlustee, from *svtvluste*, black persimmon, in Chambers County, Alabama)

*Diospyros* is a genus of ~475 species, with 80 in the Americas, 94 in Africa, about 100 in Madagascar, and 200 in Asia (Mabberley 1997). The genus is best known as the source of ebony wood, and it was favored by ancient Egyptians for making furniture. When Linnaeus ([1753] 1957) gave us the modern scientific name, the southeastern species had been known to Europeans for more than 200 years. However, within scientific circles, Caspar Bauhin first noted the trees in Europe in 1623 when he wrote that they were *Loti africanae similis indica* (Indian lotus which is similar to the African lotus) (cf. *Celtis*: Hackberry for discussion of *Lotus*). Leonard Plukenet recorded the plants in 1696. He called them *Guajacana loto arbori affinis virginiana Pishamia dicta* (Guajacana is the tree related to the lotus, from Virginia where it is called *Pishamia*). *Guajacana* seems to be the Tuscani Italian name for *Diospyros lotus*, also called *l’Ebano new* (Nero’s ebony).

Much earlier, however, persimmons were recorded in accounts from Virginia to Louisiana and north to Illinois. The de Soto chroniclers recorded persimmons in the late 1530s and early 1540s as *ameixas* [plums] (Swanton 1946), while others usually called them medlars or *Mespilus*.

In 1542, Hernando de Soto found that people on the Mississippi River made loaves of *Diospyros*. According to Hedrick (1919), the loaves were “like unto bricques, also plummes of the making and bigness of nuts and have three or four stones in them.” Presumably, this site was at the Natchez village of Guachoya, where Swanton (1939) said that de Soto’s men got corn, beans, and dried persimmons from local storage huts. That site is thought to have been near modern Ferriday, Louisiana (Swanton 1939).

Harriot ([1590] 1972) said that they were “Medlars a kind of verie good fruit, so called by vs chieflie for their respects: first in that they are not good vntill they be rotten: then in that they open at the head as our medlars, and are about the same bigness: otherwise in taste and colour they are farre different: for they are as red as cheries and very sweet: but whereas the cherie is sharpe sweet, they are lushious sweet.”

Capt. John Smith also wrote about them in 1612 in Virginia. He said, “The fruit like medlers; they call *Putchamins*, they cast them vppon [upon] hurdles on a mat, and preserve them as Pruines.” He further said, “if it be not ripe, it will drawe a mans mouth awrie with much torment; but when it is ripe, it is delicious as an Apricock” (Davidson 1999). In the same year, Strachey wrote that the *pichamins* were an “excellent plumb” (Harrington 1955).

La Salle wrote in a letter ca. 1682 that “*c’est a pimateoui et au-dessous qu’on commence à trouver d’un fruit que les Sauvages appellent piakimina, tres-ordinaire a tout la Louisiane... C’est peut-etre ce que Jolliet apelloit des greandes*” (it is at Pimateoui and below that one begins to find a fruit that the Indians call *Piakimina*, very common to all of Louisiana.... It is perhaps this that Jolliet called pomegranates) (Crawford 1978).

Henri de Tonti gave an account of a meeting between La Salle and a Taensa [Natchez] leader in Louisiana between 1678 and 1683. In that he recorded having asked to have the women “*faire des farines de bled d’Inde et des pastes d’un certain fruit quils appellent Paquimina, lequel est fort bon*” (make flour from Indian corn and paste from a certain fruit that they call *Paquimina*, which is very good) (Crawford 1978).

Henri Joutel wrote in July 1687 that the “Arkansas” [Quapaw] have “*encore d’une espece de fruit qu’il appellent piaquiminia*” (also a kind of fruit which they call *piaquiminia*) (Crawford 1978). That site was near where the Arkansas River joins the Mississippi in southeastern Arkansas. As the Quapaw spoke a Siouan language, Joutel was using the Illinois name.

Shortly afterward, Joutel recorded persimmon as one of the fruit trees growing on the Illinois River near the junction with the Mississippi. That junction of rivers is now in the suburb of St. Charles in the northwestern part of modern St. Louis, Missouri.

In 1748, Le Page Du Pratz found the Natchez using the persimmon. He wrote: “When [the persimmon] is well ripened the natives make bread of it, which keeps from one year to another, and the virtue of this bread, greater than that of fruit, is such that there is no diarrhea or dysentery which it does not arrest, but one ought to use it with prudence and only after being purged. In order to make this bread the natives scrape the fruit in very open sieves to separate the flesh from the skin and seeds. From this flesh, which is like thick porridge, and from the pulp they make loaves of bread 1½ feet long, 1 foot broad, and the thickness of the finger, which they put to dry in the oven, on a grill or, indeed, in the sun. In this latter fashion the bread preserves more of its taste. It is one of the merchandises which they sell to the French” (Swanton 1946).

Bernard Romans ([1775] 1961) said that the Choctaw in the 1760s still used persimmon, at least when their crops failed. He wrote, "They make bread of the different kinds of *Fagus*, of the *Diospyros*" and several other plants.

William Bartram wrote to physician Benjamin S. Barton in 1789 that the Cherokee and Creek used persimmon. He noted that they "have in use a vast variety of wild or native vegetables, both fruits and roots, viz.: *diospyros*, *morus rubra*, *gleditsia multiloba s. triacanthus*" and many others (Swanton 1946).

Swanton (1946) found that the Tunica who lived along the Mississippi in southwestern Mississippi mostly used corn in their diet. However, historically, they were reported to "have lived one entire month every year on the persimmons besides putting up a great quantity of persimmon bread." South of the Tunica, the Chitimacha who lived on the Mississippi delta in Louisiana also ate the fruit of the persimmon (Swanton 1946). There is now a place near where they lived that is called Plaquimine Bayou [persimmon creek; bayou from Choctaw *bayuk*].

We have documentation of *Diospyros* use by the Alabama, Apalachee, Carolina Algonquians, Catawba, Cherokee, Chitimacha, Choctaw, Comanche, Creek, Illinois [*Illiniwek*], Natchez, Quapaw, Rappahannock, Timucua, Tunica, and Seminoles, essentially people throughout its range (Harriot [1590] 1972, Swanton 1946, Howard 1985, Hann 1986, Sturtevant 1955, Crawford 1978, Drechsel 1997). Surely all of these people ate the fruits.

Fruits have been used to make beer and distilled liquor, and the seeds were roasted, ground, and used as a coffee substitute (Standley 1920–1926). Kalm ([1753–1761] 1972) provided a detailed recipe English and Swedes in New Jersey followed to make cakes, beer, and brandy of ripe fruits, and Porcher (1863) praised alcoholic beverages made from it. Tull (1999) also gave recipes for jam and bread. Swanton (1946) noted that the persimmon root sometimes was carved and Tull (1999) added tool handles and golf clubs to bring its use into the modern world.

The bark is rich in tannin and has been used as a substitute for oak in tanning leather (Porcher 1863). Black dye may be made from the bark also, but Tull (1999) preferred *D. texana* over *D. virginiana*.

Four tribes have been documented as using persimmon medicinally. The Alabama boiled roots for a tea used in "bowel flux" (Bennett 1997). The Catawba treated thrush in babies with a bark infusion (Bennett 1997). The Cherokee took medicine made from it for bowel problems, sore throat, and mouth, heartburn, bile, and liver problems, piles, thrush, toothache, and venereal disease (Hamel and Chiltoskey 1975). The Rappahannock took an infusion of the bark to treat thrush and sore throat (Moerman 1998).

Green fruits contain tannic acid and have been used against diarrhea, chronic dysentery, and uterine hemorrhage (Porcher 1863). Morton (1974) found people in the coastal region near Charleston, South Carolina using the green fruit to treat thrush in infants, and on the gums of teething children. Bark is astringent and bitter. Tea made from dried or fresh leaves is said to be rich in vitamin C (Fernald et al. 1958), but Tull (1999) did not find it that appealing.

*Dirca*

(Named for Dirce, wife of Lycus, who, after her brutal murder, changed into the fabulous fountain Dirce northwest of Thebes in Boeotia [*Voiotia*], a district in east central Greece northwest of Attica)

***Dirca palustris*.** From Britton and Brown 1897.

***Dirca palustris*** (of swamps)

*bois de plomb* (lead tree, Quebec)

*cibāgob* (dead man's [spirit?] bark, Potawatomi); *djibe'bûb* (spirit bark, Ojibwa)

*drago* (dragon, Mexico)

eastern leatherwood (in use by 1760)

moose-wood [moosewood] (by 1792 the name was applied to *Acer pennsylvanicum*, but by 1860 Asa Gray was using it for *Dirca*; the *Acer* was given the name because moose, *Alces alces*, fed on its branches; perhaps that is the reason the name was extended to *Dirca*)

rope-bark (used in a medical dictionary published in 1851)

wicopy (first recorded in [1612] 1953 by Strachey, who wrote the Virginia Powhatan word *weihkippeis*, and said it meant "hemp"; Siebert (1975) has associated this with *wikepi*, base or inner bark of linden or leatherwood; akin to Cree *wikupiy*; first connected with *Dirca* in 1778, when Jonathan Carver wrote in his *Travels through the interior parts of North America in 1776*, "The Wickopick or Suckwick appears to be a species of white wood"; related to a name applied to *Tilia*, which see)

John Clayton sent a specimen of a new shrub to European Jan Gronovius in the 1730s. When Gronovius published the *Flora Virginica* in 1739–1743, he called the plant *Thymelaea floribus albis primo vere erumpentibus* (A *Thymelaea* with white flowers, truly the first to flower). Linnaeus also studied the specimen, now deposited in the Linnaean herbarium in London, and decided it was not *Thymelaea*. So, he created the

genus *Dirca* in 1751 in a thesis defended by his student Leonhard J. Chenon at Uppsala. In *Species Plantarum*, Linnaeus ([1753] 1957) wrote, "*Habitat in Virginiae paludosis*" (Grows in Virginia swamps).

In Florida, these are rare shrubs of bluff forests and river banks in Gadsden, Liberty, and Jackson Counties. The species also grows from New Brunswick and Quebec to Minnesota, and south to Arkansas, Oklahoma, Alabama, and Florida (Fernald 1950, Gleason and Cronquist 1963).

*Dirca* has three species and is now known to be endemic to North America, Kartesz (1994) said the only other species was *D. occidentalis*, but *D. mexicana* was named in 1995 from Tamaulipas, Mexico. The plants belong to the Thymeliaceae, a family with 50 to 53 genera, and about 750 species. The family is widespread, but especially abundant in Australia and tropical Africa. Much of the family consists of toxic plants, which produce glycosides and accumulate daphin (a coumarin) or related substances (Mabberley 1997).

In the northern part of their U.S. range, where these shrubs are more common, indigenous people made wide use of them. The most common application was for cords and fibers. There are records of use as cords among the Menomini, Ojibwa, Potawatomi, and Winnebago (Smith 1933, King 1984, Moerman 1998). Fernald (1950) wrote that the wood was white, soft, and brittle, but the fibrous bark was remarkably tough and was used by indigenous people to make thongs. Gilmore (1931) identified *Dirca* at the Ozark Bluff-Dweller site in Arkansas. Then Jones (1936) found them in the Newt Kash Hollow Shelter in Kentucky. Whitford (1941) found the species used from Arkansas to Wisconsin. Mats made of the fiber came from the Bushwick Cave in Arkansas, and cloth came from the Adena Culture in Ohio. Whitford (1941) also found unprocessed fibers simply twisted into cord. The Potawatomi in Wisconsin had used the plant as the web for a bag, and the Winnebago had made a bicolored bag of *Dirca* and *Tilia*.

Perhaps as common, although not mentioned by Moerman (1998), was the incorporation of the flexible shoots into baskets (Mabberley 1997). Steyermark (1963) wrote: "The twigs are very supple and can be tied into knots without breaking. On account of their toughness, the bark and branches were used by Indians for making baskets and for tying purposes."

In spite of sometimes causing severe dermatitis, with redness, blistering, and sores (Foster and Duke 1990), the plants were used as medicines. Steyermark (1963) recorded that some individuals are sensitive to the bark, and their skin becomes irritated or blistered after contact with the fresh bark. Also he noted that the bark, if taken internally, induces vomiting and has purgative properties, and that the fruit was reputed to be narcotic. Minute doses cause burning of the tongue and salivation, but it was used in remedies for toothache, facial neuralgia, and paralysis of the tongue (Foster and Duke 1990).

At least the Algonquin, Iroquois, Menomini, Ojibwa, and Potawatomi used *Dirca* as a medicine (Smith 1933, Moerman 1998). The Algonquin used inner bark to make a laxative tea. The Ojibwa made green stalks into a physic and a diuretic remedy for urinary infections and lung troubles, and used roots to wash the hair. The Iroquois made a medicine of bark and roots for back pains, to purify the blood, to use as a purgative, and they put a poultice of branches on swellings and neck sores. As an emetic, it was used during pregnancy, for kidney problems, consumption, and venereal disease. The Menomini and Potawatomi used it as a diuretic (Smith 1933, King 1984).

Five phenolic glycosides were found in *D. palustris*. These chemicals showed variable activity as enzyme inhibitors and have potential as antioxidants and antiinflammatory agents (Ramsewak et al. 1999).

Five insecticidal compounds have been isolated from the seeds (Ramsewak et al. 2001). The triglycerides were effective against the yellow fever mosquito (*Aedes aegyptii*) larvae and exhibited potent feedingdeterrent activity against larvae of corn earworm moth (*Helicoverpa zea*), gypsy moth (*Lymantria dispar*), lackey moth (*Malacosoma disstria*), and tussock moth (*Orgyia leucostigma*).

*Dirca occidentalis* yielded two antileukemic daphnane esters, Pimelea factor P2 (I) and dircin (II), plus three lignans, (-)-medioresinol (III), (+)-syringaresinol (IV), and (-)-lariciresinol (V), as well as the coumarin daphnoretin (VI). All were found to be cytotoxic constituents (Badawi et al. 1983). Genkwa nin (I), (±)-lariciresinol (II), and sitoindoside II (IV) also were active against cancer (Suh et al. 1995).

### *Distichlis*

(Rafinesque named this grass from Greek *distichos*, two-ranked, alluding to the leaves in two rows)

*Distichlis spicata*. Drawn by  
P.N.Honychurch.

*Distichlis spicata* (spiked, the inflorescence)  
alkali-grass

*chépica* (Chile)  
*grama [brama]* (grass, Chile); *grama de costa* (coastal grass, Cuba)  
*hapí pahí* (*hapí*, salt, *pahí*, grass, Koasati; this may belong here as they once burned it and leached the ashes for salt)  
*mu'umk vashai* (sharp grass, Akimel O'odham [Pima], Arizona)  
*'onk wasai [onk vashai]* (salt grass, Tohono O'odham, Arizona, Sonora)  
 [desert, inland, seashore] salt grass; *pasto salado* (salt grass, Chile);  
*zacate salado* (salt grass, Sonora)  
 spike-grass  
*yerba del burro* (burro herb, New Mexico)

*Distichlis* is a genus of four or five species, confined to saline and alkaline habitats in the Americas and Australia (Felger 2000). *Distichlis spicata* has an unusually large range. It is found from the Gulf of St. Laurence, Cape Briton, Prince Edward Island, and New Brunswick in Canada, along the eastern U.S. coast to Mexico, and south to Belize (Fernald 1950, Balick et al. 2000). In the West Indies, it appears to be confined to the Bahamas, Cuba, and the Cayman Islands (Leon and Alain 1946–1953, Correll and Correll 1982, Proctor 1984). It also grows along the Pacific Coast from Washington, south along both coasts of Baja California and down to the Guaymas region of Sonora, and in Sinaloa, thence into South America (Brako and Zarucchi 1993, Jorgensen and León-Yáñez 1999, Felger 2000).

In spite of this extensive range, the records of people using the grasses are confined to the south-western United States. Moerman (1998) found it being used among the Cahuilla, Kawaiisu, Tubatulabal, and Yokut, all southern and central California tribes.

The Cahuilla, Tubatulabal, and Yokut obtained salt from *Distichlis* (Ebling 1986, Moerman 1998), but they used different techniques. The Cahuilla burned the grass to remove the salt and used the salty ash as a condiment. These people did not salt the food when they cooked, but simply put a pinch of salt in the mouth while eating (Ebling 1986). The Tubatulabal pulled up the grass, stacked it in a basket, and thrashed off the salt much as people handle grain. They were able to gather several hundred pounds of salt in this manner (Ebling 1986). The Kawaiisu used both dried and green grass in water to make a beverage. The Tubatulabal used the leaves and stems as food. The Cahuilla also used the leaves for brushes, especially to remove cactus thorns.

There were also medicinal applications. The Kawaiisu took a decoction of the plants for insect bites, to slow a heart beating too fast, as a laxative, and to treat gonorrhea. The Yokut used a salt extract to treat bad colds and to improve a lost appetite.

Rea (1997) found the Pima still remembered the plant and its name, but they used it only for cattle food. Nonetheless, if the plants on the Colorado River delta are considered the same species, they and others ate the seeds. Some consider those plants to be *D. spicata* ssp. *stricta*, while most now call them *D. palmeri* (Felger 2000, Hodgson 2001). These plants were harvested in great quantities by the Cocopa prior to the devastation of the ecosystem by construction of upriver dams. Those people ate the seeds in *atole*.

***Dodonaea*: Varnish-Leaf**

(Named in honor of Dutchman Rembert Dodoens)

***Dodonaea viscosa*.** From Little and Wadsworth 1974.

A particular pinelands on the Big Cypress Seminole Reservation has an abundance of varnish-leaf (*Dodonaea viscosa*) in the shrub layer. One of our students had difficulty remembering the plant, and was quizzed each time we went there. Finally, he answered, “varnish-leaf” without even looking when he was asked about any plant in that area.

Many people have a hard time recognizing this shrub because there is nothing very distinctive about it except the shiny leaf surface. The leaf certainly looks like it has been varnished, and that must have been the reason for originating the common name.

Still, that seems like a highbrow name for a plant since most poor people (who typically give such names) could not afford that expensive covering. The word “varnish” itself has been in English since at least 1341 and had taken on a variety of meanings by the 1500s. So, even if poor people could not afford the product, they might have heard about or seen items with that coating. Making me more suspicious that the name is a recent innovation is that neither Chapman (1897) nor Small (1913) cited the common name. It is only with Small’s (1933) flora of the southeastern United States that the name appears.

Names more likely to have originated early include candlewood (Bahamas), hop-bush (Panama), hop shrub (Barbados), native hops, and sticky hop bush. Those names convey practical uses for the plants, either as torches or candle substitutes, or in making beer. One Spanish name also mirrors the English candlewood—*ocotillo* (little torch, from Náhuatl, *ocotl*, Guanajuato, Hidalgo). Others note the sticky leaf surface, including *chilca* [*chirca*] (mostly applied to a resinous composite, Costa Rica), *chrica de monte* (wild *chilca*, Costa Rica), and *gui laga citi* [*qui-laga-cijti*] (*gui*, cane, *laga*, flower, *citi*, sticky,

Zapotec, Oaxaca). The Zapotec name has also been rendered as *yak cij* (*yak*, tree, *cij*, sticky, Oaxaca). Closely related to those names is *incienso* (incense).

As the names candlewood and *ocotillo* suggest, the wood is easily ignited and that, along with the crushed leafy twigs, is used for torches in the Bahamas, Mexico, and Panama (Duke 1967, 1972, Morton 1981). Since the plant is known to some as “hops,” it would be correct to conclude that they use it in place of *Humulus lupulus* to make beer (Panama, Barbados, USA).

The Miccosukee were comparatively late arrivals in peninsular Florida, and their only

*taḳʰi*

name for the plants is *taḳʰi* [*takri*, *taḳʰi*] (bush). There is no indication of what their predecessors within the range of the plants might have called this bush. In Florida, the species grows from St. Johns County down the east coast to Key West and up the west coast to Hernando County. Outside of Florida, the plant is widespread, growing in the Bahamas, West Indies, southern Arizona, and through Mexico and Central America to Chile and Argentina. This same species is widespread in the Old World tropics.

As there are records that the plants are used by people almost everywhere they grow (Prendergast and Pearman 2001), people in Florida probably used them. Uses range from purely utilitarian to medicinal. Because the plants typically have small, multiple stems, they are easily turned into brooms. *Dodonaea* has been used for brooms at least in Brazil, where they are called *faxina vermelha* (yellow broom [cleaner]), *vassoura de campá* (wild broom), and *vassoura vermelha* (yellow broom).

Although the stems typically do not grow very large, they do produce enough wood for some uses. In Mexico, a common reference is to *jaras* (arrows, the Spanish from Hebrew *khara*, to cast, Oaxaca), and *jarilla* [*jaril*] (little arrow, Sonora, Morelos, Oaxaca). Not only do those names reflect past usage for arrowmaking, but *jarita* also has been used for *Salix* (Curtin 1947). When large enough, the close-grained, brown hard wood is used for engraving, turning, toolhandles, and walking sticks. People in Hispaniola use the wood in similar ways.

There is a variety of common names that either confuse or compare *Dodonaea* with other species. Some use the name *castaño* (chestnut), surely because of the edible seeds. Mayans compare the plants with *Talisia olivaeformis* (Sapindaceae) with the name *huayun ak* (*huaya* is *Talisia*, *ak*, vine). Both have edible seeds.

In Puerto Rico, *Dodonaea* is sometimes called dogwood, probably because both are bitter. Also because of the bitter flavor, it is compared with sorrel (*Oxalis*, Oxalidaceae) in the names switch-sorrel (Jamaica, Arizona) and *mangle-oseille* (mangrove sorrel, Guadeloupe, Martinique). The French name also makes a comparison with mangroves, as do *manglier petites* (little mangrove, Haiti) and *pativier* (variant of *paltuvier*, mangrove, French Antilles). That comparison is harder to understand because varnishleaf is an upland plant. To some they are *granadina* [*granadillo*, *grenadina*] (little passionflower, Dominican Republic, Baja California), an allusion to species that do not seem similar to me.

Since the time of José Celestino Mutis (1732–1808), Colombians have called the species *hayo* (coca) or *hayuelo* [*ayuelo*] (fruit of the coca). Some resemblance of the habit and leaves is apparent, and Mutis is said to have explained to disappointed users that this was not the real coca (Pérez-Arbelaez 1978).

Presumably, the following indigenous words are simple—*chilim* (Morton 1981), *sen* (Morton 1981), *tarachiqui* (Opata, Sonora), and *pirimu [jirimu]* (Tarascan, Michoacán).

The most common use throughout the range of the species is as medicine. Some names that allude to medicines are *bois guillaume* (William's tree, French Antilles), *chamiso* (also applied to a medicinal grass and to *Ademostoma*, Rosaceae, Puerto Rico, Argentina, Uruguay), *chamana [chanamo]* (*chan* is *chia* or *Salvia*, Colombia, Peru), *chapuliztle*, [*chapul-ixctli*, *chapuliztoli*] (*chapul*, grasshopper, *ichtli*, fiber, because grasshoppers eat the leaves, Náhuatl), *chulita* (pretty little one), *cucaracha* (cockroach, Dominican Republic), *cuerno de cabra* (goat's neck, Oaxaca), *erva de veado* (deer herb, Brazil), *guachomó* (little orphan, Guarijío), *guatacán* (big ear), *guitarán [quitarán]* (big guitar, Puerto Rico), *hierba de la cucaracha* (cockroach herb, Durango, Patoni), *hierba del campo* (country herb), *munditos* (little worlds, Hidalgo), *palo de reina* (queen's herb), *palo de rey* (king's herb, Dominican Republic), and *pinchon* (big spine, Trinidad). The name *plomito* may be an allusion to lead (*plomo*), which would imply medical use, or to doves (*palomd*), which would not.

The leaves and their resinous exudate are aromatic, bitter, astringent, sudorific, purgative, and a febrifuge (Morton 1981, Hocking 1997). Both leaves and/or wood decoctions have been used against fevers (Mexico, Panama, Brazil). The leaf decoctions are also used against rheumatism and venereal disease (Mexico, Brazil). Bark extracts have been used in astringent baths and fomentations (Mexico, Brazil) to provide relief from several problems, including rheumatism (Amabeoku et al. 2001). Although people in some areas eat the seeds (Mexico), they and the entire plant contain enough saponin that people have also used them as *barbasco* to poison fish (Panama, Colombia). Leaves are chewed as a stimulant—maybe that is why Colombians confuse it with coca—or to treat toothache (Panama). The sap is applied to clear tumors (Brazil). Sap with other plant parts is used in cataplasms in the treatment of flatulence (Brazil), gout, and venereal diseases (Mexico, Brazil). Leaf infusions are hemostatic for people and animals (Colombia, Panama).

Some of the chemicals known to be in the plants include flavonoids and other polyphenols in the leaves and their exudates (Rao 1962, Paris and Nothis 1970, Sachdev and Kulschreshtha 1983, van Heerden et al. 2000). There are also diterpenoid acids based on entlabdane and ent-clerodane skeletons (Sastry and Nayudamma 1966, Jefferies and Payne 1967, Hsü et al. 1971, Abdel-Mogib 2001, Ortega et al. 2001), and triterpenoids (Azam 1993). The bark contains tannins (Sastry and Nayudamma 1966). Fruits, seeds, and stems contain saponin esters, called dodonin and dodonosides A and B, with anti-exudative, phagocytosis-enhancing, and molluscicidal properties (Wagner et al. 1987). There are also prosaogenins (Han et al 1995). In addition, the plants contain coumarins and the lignocoumarins cleomiscosin A and B (Rojas et al. 1992, 1996, Gonzalez et al. 1993, Hemlata and Kalidhar 1994, Ghisalberti 1998, Siddiqui 1998). Laboratory studies suggest that crude methanol extracts are effective in inhibiting *Candida albicans*, *Bacillus subtilis*, *Escherichia coli*, *Pseudomonas aeruginosa*, and *Staphylococcus aureus*. Ethanol extracts showed similar inhibition of other bacteria.

Attempts have been made to divide the variability in the pantropical plants into several species and varieties. Most people still follow West (1984) in recognizing *D. viscosa* as a single species, although there are 68 species in the genus. Some 59 of those species are endemic to Australia (West 1984, Mabberley 1997).

This is one of comparatively few plants known since the 1700s that does not have a name created by Linnaeus. *Dodonaea* was created by Philip Miller in 1754 to honor Dutchman Rembert Dodoens (1517?– 1585), one of the foremost physicians and herbalists of his day. Indeed, Linnaeus did not know what to do with these plants. In his *Hortus Cliffortianus* published in 1738, and in his *Flora Zeylanica* from 1747, Linnaeus called the plants *Dodonaea*. Then, in 1753, he changed his mind and named them *Ptelea viscosa*. To show how confused Linnaeus was, *Ptelea* is in the Rutaceae, and *Dodonaea* belongs in the Sapindaceae. It was not until 1760 that Jacquin created the binomial we now use.

### ***Drosera*: Sundews**

(Greek *droseros*, dewy)

***Drosera*.** *Drosera filiformis* (left).  
*Drosera intermedia* (right). From  
Britton and Brown 1897.

“This herbe is of a very strange nature and maruellous: for although that the Sunne doe shine hot, and a long time thereon, yet you shall finde it alwaies moist and be-dewed, and the small haire thereof alwaies full of little drops of water: and the hotter the Sun shineth upon this herbe, so much the moystier it is, and the more be-dewed, and for that cause it was called Ros Solis in Latin, which is to say in English, the dewe of the Sun, or Sundewe.” Those words were written by Henry Lyte in 1578, as a translation of Rembert Dodoens’s herbal of 1554. Throughout history, everyone has been fascinated with sundews.

When I took classes where sundews grow, I challenged the students to walk barefoot over these carnivorous plants to “test” the idea that they digest their prey. No one ever took me up on that suggestion. Even if they had, they would have no problem. The chemicals that dissolve their insect prey have no impact on human feet—I tried it!

We now think of sundews as the stereotypical plants that have turned the tables on insects, and “eat” them instead of being eaten. However, that is a relatively new view of

the herbs. The early Latin speakers called them *ros solis* or *rosa solis* (sun rose) because of a fancied resemblance to the sun. That name carried over into Spanish (*roscío del sol*), Portuguese (*rorela*), and French (*rossolis*), but the sun comparison is not confined to the languages related to Latin. Norwegian *soldogg*, German *Sonnentau*, and Dutch *sundauw* all mean “sundew.”

“Sundew” may not, however, have been the original sense. Britten and Holland ([1886] 1965) note an old German name *sindau*, which meant “ever-dewy.” They said that name was from Anglo Saxon, Old Saxon, and Frissian *sin*, “ever,” rather than from “sun.” Another form of the word, as *Singreen* and *Syndaw*, is applied to *Alchemilla* (Rosaceae). About the latter form, Parkinson wrote in 1640 that it was “from the Germane name *Sinnaw*, because the hollow crumplings and the edges also of the leaves, will containe the dew in droppes like pearles, that falleth in the night.”

In English, the first appearance of the name sundew seems to have been in the British physician William Turner’s *Herbal*, published in 1568 (Coffey 1993). However, Gaelic speakers of western Europe had been using names for these small plants of bogs and marshes far longer. Speakers of the Celtic languages sometimes called these wetland plants *lus na fearnaich* (plants of the bloody-flux). That name came about because the farmers who grazed their cows and sheep in wet meadows thought the plants caused a plague in their animals. Indeed, from one view it seemed logical. The plants were red; animals that grazed where the plants grew were defecating bloody-red stools. That looks like cause and effect. Actually, the *fearnaich* was caused by something totally different and not the plants at all, but it shows the danger of jumping to conclusions based on limited information.

Other people noticed that cattle will not eat sundews, probably because they taste bitter and caustic (Watt [1889] 1972). This taste may be due to the acidic polysaccharide they contain. That acid (up to 4% by volume) is in the sticky droplets that catch insects (Mabberley 1997). This material not only helps trap, but it also kills insects by clogging their spiracles (breathing tubes).

Another Gaelic name for sundews is *lus na ghadmainn* (plant of the insects), showing the old observation of insect-catching (Vickery 1995). Sundews were also known as *lus an-t-soluis* (herbs of the sun), *lus na greih* (sun plant), *lus na eiyrts* (plant of strength), and *lus y ghruiahtys* (plant with a sunface). These last two names are associated with a belief that they were a potent aphrodisiac (Vickery 1997). The plants “clung” to anything that touched them, and the leaves were used to transfer that tendency to a person with whom someone wanted to fall in love. It probably worked as well as mistletoe (see Austin 1998a).

From the beginning, these small reddish rosettes were also used as medicines. That was the context of their first mention by Turner, and subsequently by other herbalist-physicians like Joachim Camerarius in 1588, John Gerarde in 1597, Gaspar Bauhin in 1623, and Nicholas Culpeper in 1653. These authors used phrase names for sundews, such as *Salsirora sive ros foils* (sprinkled with dew or rose leaf) and *Ros folis folio rotundo* (rose leaf with round leaves). Linnaeus eliminated the phrase name in 1753 and placed the five sundew species known to him in the genus *Drosera*.

Traditionally, the sundew was made into a tea or tincture and used to treat dry, spasmodic coughs, asthma, arteriosclerosis, chronic bronchitis, and as an aphrodisiac. For example, Gerarde ([1597] 1975) thought the plants a “remedy for consumption.” Their

limited effectiveness against bronchial problems is due to the quinones in the leaves (Mabberley 1997). William Turner wrote in 1568: "Our Englishmen nowadays set very much faith by it, and hold it good for consumptions and swooning, and faintness of the harte." Gerarde ([1597] 1975) even said that there was a "liquor made thereof, which the common people call Rose solis" (Britten and Holland [1886] 1965). That liqueur was popular in Britain, France, and Germany during the 17th century for its reputedly fortifying and aphrodisiac properties (Bown 1995).

Proteolytic enzymes are the basis of sundew use to treat warts and corns. Culpeper (1653) said that the sundew flowered in June, when the leaves were "fittest to be gathered." He believed: "Sun rules it, and it is under the sign of Cancer. The leaves, bruised and applied to the skin, erode it, and bring out such inflammations as are not easily removed. The juice destroys warts and corns." Culpeper's astrological references were spurned by the medical profession of his time. This mumbo-jumbo was adapted, partly out of context, from the Arabic magicians and alchemists, but has remained surprisingly popular then and now.

Plumbagin in sundew is active against Gram-negative bacteria (Foster and Duke 1990). Among the many Gram-negative bacteria are those that cause typhoid fever (*Salmonella typhi*), food poisoning (*Salmonella* spp., *Shigella* spp.), and Legionnaire's disease (*Legionella*).

Not surprisingly, people in various parts of the globe have learned to use different species in similar ways. Sundews are used in Chinese medicines against lung diseases, dysentery, sore throat, and ear infections. The Miccosukees (Sturtevant 1955) used the plants to treat ringworm, and called them *oláyikcí* (ringworm medicine). Their Creek-speaking relatives call sundew *hilápa hiliswa* (*helvpa*, ringworm, *heleswa*, medicine), as do the Chickasaw with *halambo tish* (*halambo*, ringworm, *ittish*, medicine). The Kwakiutl of British Columbia, Canada, treat warts, corns, and bunions as did the Gaelic speakers of Europe (Moerman 1998). These Canadian Americans also used sundew as an aphrodisiac, saying that it is a "medicine to make women love-crazy."

People in India have a variant of the topical remedy, where the mashed leaves are applied to skin problems (Watt [1889] 1972). This technique raises a blister as a "counterirritant." This treatment seems akin to hitting yourself on the thumb with a hammer to make a headache disappear. Yet, strange as this may seem, the Indian logic sometimes works. The same counterirritant concept applies to the modern use of capsaicin (the hot stuff) from chile peppers (*Capsicum* spp., Solanaceae) in over-the-counter remedies for arthritis and shingles. Western medical researchers finally found that the chemicals in the treatments "confuse" the nerve endings reporting the problems (pain, itching, or whatever) to the brain, and temporarily stop the symptoms. The method is not a cure, but it provides relief while the body fights off the malady.

Sundews belong to the family Droseraceae, which contains four genera (Mabberley 1997). Remarkably, these plants are related to carnations and their relatives (Williams et al. 1994). The four genera are *Aldrovanda vesiculosa* (central Europe, Asia to northeastern Australia), *Dionaea muscipula* (endemic to Carolinas), *Drosera* (~110 spp., worldwide), and *Droserophyllum lusitanicum* (Portugal, South Africa, Morocco). All are carnivorous and grow on nitrogen-poor acidic soils or rocks. Most are in wetlands such as marshes and bogs, although *Aldrovanda* is aquatic, and *Droserophyllum* grows in dry

areas. Their adaptation of carnivory allows them to get enough nitrogen to carry out their life cycles.

Five species of *Drosera* are in Florida; the others are *D. brevifolia*, *D. filiformis*, *D. intermedia*, and *D. tracyi* (Schnell 1976, Wunderlin 1998). *Drosera capillaris* is the most common and widespread, also occurring in Cuba, Hispaniola, Jamaica, Puerto Rico, Trinidad, Guyana, and Central America.

Discovery of carnivorous plants in the 18th century led writers and sensationalists to imagine “man-eating” plants in the “jungles” of unexplored lands. That myth persists and is rejuvenated periodically in Hollywood productions, like *The Little Shop of Horrors*, where a monster plant demands, “Feed me!”

Some years ago an undergraduate asked me, in all seriousness, “Where do the man-eating plants grow?” I dutifully explained that no such organism existed, but he really did not seem to buy the story. So, I dreamed up a hypothetical case of two kinds of people-eating plants living near each other. The students were asked to use the logic techniques we had studied, and the information I provided, to determine if the plants on opposite sides of a river were different species. I am not sure they appreciated the irony of my example, but for a change, they did laugh during that exam.

### *Drypetes*

(Martin Hendriksen Vahl, 1749–1804, named these from Greek *drypetes*, fruit ready to fall from the tree, fully ripe; from *drys*, tree, and *petein*, to fall)

*Drypetes lateriflora*. Drawn by  
P.N.Honychurch.

***Drypetes lateriflora*** (flowers produced laterally in leaf axils)

*bois côtelette* (cutlet tree, Haiti)

*cirulela de Guyana* (Guiana plum, Puerto Rico);

Guiana plum (Florida, Bahamas, Jamaica);

Guinea plum (Puerto Rico)

*cueriduro* (leathery and hard, Cuba, Puerto Rico)  
*hueso [de monte, blanco]* ([wild, white] bone, Cuba)  
*mula* (mule, El Salvador)  
*pae Manuel* (father Manuel, Dominican Republic)  
*ramón blanco* (white tree, Cuba); whitewood (Jamaica)

In 1788, Olaf Swartz named trees he found in the Caribbean *Schaefferia lateriflora*, a genus now included in the Celastraceae. It was not until 1892 when C.W.L.Krug (1833–1898) and I.Urban (1848–1931) realized that the plants were actually members of the Euphorbiaceae and moved the species to *Drypetes*. This is now a genus containing about 200 tropical species in the Americas, Africa, and Asia (Mabberley 1997). Many of them provide timber, but others are used in medicines and as chew-sticks.

Wood is used in construction (Liogier 1974); fruits are eaten (von Reis and Lipp 1982).

# E

## *Echinacea*

(From the Greek *echinos*, a hedgehog, referring to the prickly receptacle)

### *Echinacea purpurea* (purple)

coneflower (applied to *Rudbeckia* by 1817, but later denoting a number of different Asteraceae)

[eastern] purple coneflower (*Echinacea* was meant, with or without the prefix “purple,” since at least the time of Asa Gray in 1857)

*Igelkopf* (hedge crown, German)

Linnaeus called these plants *Rudbeckia purpurea* in 1753. Then, in 1794, Conrad Moench created the genus *Echinacea* to accommodate species in this group. Nine species are now known, all native to eastern North America (Mabberley 1997). Perhaps the Muskogean names were related to Koasati *innatho: pahissí* [*innotho:pahissi*] (*innathó:pan*, toothache, *ahissí*, medicine) for *E. pallida*.

The Choctaw chewed the root of *E. purpurea*, and swallowed the saliva or made a tincture of the root to relieve coughing (Campbell 1951). They used it in a similar way to relieve indigestion. The Delaware combined the roots with those of staghorn sumac (*Rhus typhina*) to treat venereal disease (Moerman 1998).

Considering the wide use of *E. angustifolia*, it is surprising how little seems to be recorded of indigenous people using *E. purpurea*. Foster and Duke (1990) note that both species are now used for identical purposes in the herbal trade and imply that historically that was also true. The people of the Great Plains, from at least the Cheyenne to the Lakota, considered *E. angustifolia* a panacea and magical herb (Vogel 1970, Swerdlow 2000).

Gilmore (1919) said Missouri River tribes used *E. angustifolia* more than any other plant. The Dakota called it *ichali-pe-hu* (*ichali-pe*, whip, *hu*, plant), and the Omaha and Ponca said *hika-hi* (*mika*, comb, *hi*, plant), *ikagahai* (to comb), or *inshtogalite-hi* (*inshta*, eye, *galite*, comb, *hi*, plant). The Pawnee said it was *ksapitahako* (*iksa*, hand, *pitahako*, to whirl), because of a game children played with it. Another name they used was *saparidu kahts* (*saparidu*, mushroom, *kahts*, medicine) because the head resembles a mushroom. Moerman (1998) listed this species as important among the Blackfoot, Cheyenne, Dakota, Kiowa, Meskwaki, Montana, Omaha, Pawnee, Ponca, Teton, and Winnebago. *Echinacea pallida*, sharing much of its range, was used similarly. These two were used to treat snakebites, spider bites, cancers, toothaches, burns, sores, wounds, flu, and colds.

Modern research shows that *Echinacea* has cortisone-like activity, and that it is antiviral, bactericidal, insecticidal, and an immunostimulant (Foster and Duke 1990, Swerdlow 2000, Duke et al. 2002).

### *Echites*

(Patrick Browne named this from Greek *echis*, a viper, referring to the poisonous nature and twining habit of the plant; Pliny, A.D. 23–79, used the word *echites* for a kind of stone)

***Echites umbellata*. Drawn by  
P.N.Honychurch.**

***Echites umbellata*** (having partial or secondary umbellate flower clusters)  
*bejuco de leche* (milk vine, Central America)

Danish (Bahamas)

Devil's potato-root (Bahamas); wild potato (Bahamas)

maroon weed (possibly alluding to the "Maroons" of the Cockpit country, Jamaica)

rubber-vine (Florida, Bahamas)

savannah flower (Jamaica)

Patrick Browne created this genus in 1756 when he published *The Civil and Natural History of Jamaica*, but provided no valid species epithet. Jacquin then formalized the concept by naming this species in 1760. The genus contains six Caribbean species (Mabberley 1997).

Used on a sore leg, it supposedly will cause vomiting if the wound is poisoned (Ayensu 1981). Several of the common names note the poisonous nature of the plants. Barham, in his *Hortus Americanus* published in Jamaica in 1794, wrote that it was a widely known poison (Grimé 1976). Perkins and Payne (1978) simply noted that the root and its milky sap have not been studied chemically. Perhaps *E. umbellata* has chemical constituents similar to plants reported as *E. hirsuta*, although they are correctly in the

genus *Mandevilla*. That Old World species has the flavonoids naringenin, aromadendrin (dihydrokaempferol), and kaempferol; the coumarin fraxetin; the triterpene ursolic acid; and the sterol glycoside sitosteryl glucoside (Chien et al. 1979).

### *Eleocharis*

(Robert Brown named this “beauty of the marsh”; from Greek *heleos*, a marsh, *charts*, grace, beauty)

***Eleocharis equisetoides*.** From  
Institute of Food and Agricultural  
Sciences.

*giunco tondo* (round juncus, Italian) *héléocharis* (from *Eleocharis*, French)

*jonc* (Haiti) and *junco* (Cuba, Dominican Republic, Puerto Rico; common names applied widely to this genus and others based on the Latin *iuncus*, for a rush, derived from *iugere*, to tie or bind, from the use of stems for tying); *junquillo* (little juncus, Dominican Republic, Puerto Rico)

*sivaks* (*siv*, rush or reed, Norwegian)

spike-rush ("spike" has been used for a plant inflorescence since about 1711)

*Sumpfried* (*Sumpf*, swamp, *Ried*, reed, German)

*tulillo* (little tule, from *tollin* or *tullin*, Náhuatl; *tule* is applied to both *Juncus* and *Typha*, Sonora)

*Wasserpest* (water pest, German)

***Eleocharis equisetoides*** (resembling *Equisetum*)

jointed spike-rush

jointed spike-sedge

*pahifamí:câ* (*pv'he*, grass, *fymece*, sweet [smelling], Creek);

*pahifotóhli* (sweet [smelling] grass, Mikasuki)

***Eleocharis geniculata*** (bending like a knee-joint) (= *E. caribaea*)

*bioro* (Arawak, Suriname)

Canada spike-rush

*i:kana cokhíssi* (*ekvny*, ground, *kokhesse*, whiskers, Creek); *yaknicó:skí* (ground whiskers, Mikasuki)

*kiririma* (Carib, Suriname)

road-grass (Florida)

[Canada] spike-sedge [spike sedge] (Florida)

***Eleocharis interstincta*** (spotted, referring to the septa of the culms or stems)

*bioro* (Arawak, Suriname)

*ça* (Osage; mats called *ça-zhin-ga* [*zhin- ga'* small] made from it; a sacred plant used to make the shrine of the *wa-xo'be* or Sacred Hawk, a deity)

knotted spike-rush

***Eleocharis rostellata*** (little-beaked, the seed)

[beaked, traveling] spike-rush

*Eleocharis*, a sedge genus with about 120 species, is widespread; Mabberley (1997) says it is cosmopolitan. The common name spike-rush came about because of the slender spikelike inflorescence on a rushlike plant. At least the larger of the species have been used around the world in weaving and making baskets, bedding, mats, and similar items. For example, in Hispaniola, *E. interstincta* stems are used in households to make seats, chairs, and mats, and as stuffing in pillows and similar items (Liogier 1978).

Oddly, no weaving uses have been recorded among the Seminoles, although they call it by the same name as the grass they use in weaving baskets, *pahifamí:câ* (*pvhe*, grass, *fymece*, sweet). Instead, *E. equisetoides* was used to make beads. No explanation is given by Sturtevant (1955), but presumably the jointed stems were strung. *Eleocharis geniculata* was used in a medicine by the Seminoles (in a mixture with several other plants) to treat "Fire Sickness," "Thunder Sickness," and urine retention (Sturtevant 1955). In Hispaniola, *E. interstincta* is used as a diuretic, against stomachache (Liogier 1978). *Eleocharis rostellata* was used as an emetic by the Raman Navajo (Hocking 1997, Moerman 1998).

***Elephantopus***

(From Greek *elephas*, elephant, *pous*, foot, said to be a translation of an aboriginal name in India)

*Elephantopus elatus* (high, lofty) (as *E. tomentosus*)  
 devil's grandmother (New England)  
 [woolly] elephant-foot (USA)  
*lengua de vaca* (cow's tongue, Puerto Rico)  
*sikohákcobi* (pig ear, Mikasuki); *sokkaha:ckô* (*sokhv*, pig, *hvcko*, ear, Creek)  
 tobacco-weed

*Elephantopus* was named by Linnaeus ([1753] 1957), when he described Indian and American species. An Italian professor of botany in Bologna, Antonio Bertoloni (1774–1850), named this American species in 1850, although numerous subsequent students of the flora considered it the same as *E. tomentosus*. There are about 30 species in tropical regions of the world (Mabberley 1997).

Several species in the genus are used medicinally, with *E. scaber* used in Colombia and Brazil as a tonic, febrifuge, and diaphoretic against cough, bronchitis, and asthma (Roig 1945). Although Sturtevant's (1955) informants considered it "useless," former reports of names suggest it may have been used much as *Chaptalia* (which see).

***Encydia***

(From Greek *enkyklios*, *encyklia*, round or circular; Latin *encyclios*, belonging to a circle, the labellum encloses or encircles the column)

***Encyclia cochleata*** (shell-shaped, an allusion to the labellum, which resembles a clam shell) (= *Epidendrum cochleatum*, *Prosthechea cocheata*)  
*cañelo* (little cane, Cuba, Puerto Rico)  
*cangrejitos* (little crabs, Dominican Republic)

***Encyclia coccleata*.** Drawn by  
P.N.Honychurch.

[Florida] clam-shell orchid [clamshell orchid] (Florida); cockle-shell orchid (Puerto Rico); shell-orchid (Bahamas); *conchitas* (little shells, Dominican Republic)

*flor de San Juan* (St. John's flower; presumably St. John because it flowers near this saint's birthday on 24 June, Venezuela)

*guiguite [quiquite]* (Haiti)

*javitas* (Dominican Republic)

*orquidea negra* (black orchid, Puerto Rico)

*ts'aak* (glue, Huastec, San Luis Pososí)

Sir William Jackson Hooker (1785–1865) named this genus in 1828. In 1955, Albert Marie Victor Lemée (1892–1900) moved Linnaeus's *Epidendrum cochleatum* into *Encyclia* in his *Flore de la Guayane Française*. Some 235 American orchids are now put in *Encyclia* (Mabberley 1997).

“Root sap” (pseudobulbs?) is used as glue to make musical instruments and in medicinal baths to treat weight loss (tuberculosis) (Alcorn 1984). Pseudobulbs are a source of mucilage (Hocking 1997).

### ***Epifagus***

(Thomas Nuttall named this parasitic herb with Greek *epi*, upon, *phagus*, the beech)

***Epifagus virginiana*.** From Britton and Brown 1898.

***Epifagus virginiana*** (of Virginia)

beech drops [beechdrops] (applied since at least 1876 to this parasitic plant and equated with “cancer-root”)

cancer-root (first used in 1714 for this plant added to a mixture to cure “cancer,” a term not always applied in the sense of a malignant growth; John Gerarde in 1597 referred to cancerwort, but that meant either *Linaria* or *Veronica*)

Although *Fagus* is circumboreal, there is a single species of *Epifagus*, which is parasitic on the roots of North American *F. grandifolia* (Mabberley 1997). Perhaps this American endemic is a remnant of differential extinction during the Pleistocene.

The Iroquois used an infusion of the plant to treat diarrhea (Moerman 1998). Homeopathic physicians used the root as a vulnerary, especially on sores and cankers (Hocking 1997).

***Epigaea***

(From Greek *epi*, upon, and *gaia*, the earth, alluding to the creeping habit)

***Epigaea repens*** (running on the ground)

*Bodenlorbeer* (ground laurel berry, German); ground-laurel

*fleur de mai* (May flower, Quebec)

gravel weed [plant] (used by Shakers to treat kidney stones)

ground hog’s forehead (North Carolina)

Mayflower (not because it blooms in May, but according to legend, the Pilgrims saw this flower on landing at Plymouth and named it after their ship, cf. Coffey 1993)

moss beauty

***Epigaea repens*.** From Britton and Brown 1897.

mountain [winter] pink

rough-leaf

terrapin's foot ("terrapin" is the box turtle, *Terrapene* spp. Apparently both words were derived from the Algonqian word *torepe* and used in English by 1612. Related words are Abenaki *turepé* or *tourepé*, and Delaware *tulpe*. Breaking one of his own "rules," Linnaeus adapted an indigenous word into one that only resembles Latin as *terra*, the earth, and *pene*, nearly; used in North Carolina.)

trailing arbutus (compared with the "strawberry tree" of Europe, *Arbutus unedo*)

*wa'bi'gon* (white flower, Potawatomi)

Plukenet described and illustrated a small plant he called *Pyrola affinis repens fruticosa* (Prostrate woody shrub similar to *Pyrola*) in 1696. Linnaeus knew the plants from both Canada and Virginia, and realized they were unlike anything in Europe. He called them *Epigaea* because of their prostrate growth (Linnaeus [1753] 1957). This genus has a single species in eastern North America, a second one in the Caucasus and Asia Minor, and a third one in Japan (Mabberley 1997).

The Potawatomi of Wisconsin considered these their tribal flowers, and thought they were sent directly by their deity, called *kīti'manītowīwin* (Smith 1933). The plants grow intermixed with mosses, flower in May, and bear fruit in July. Apparently, the Japanese do not revere their species, but they eat the fruits (Ohwi 1965).

The Algonquin in Quebec used an infusion of the leaves to treat kidney problems (Moerman 1998). The Iroquois made a compound mixture of plants including these to treat labor pains and rheumatism; a decoction of the whole plant for the kidneys; or a simple decoction of leaves to aid digestion (Moerman 1998). The Cherokee made a decoction to induce vomiting, for use as an infusion to stop diarrhea in children and to treat kidney and chest problems (Hamel and Chiltoskey 1975).

Eclectic physicians used the plant to treat bladder problems, particularly kidney stones; it contains the glucosides arbutin, urson, and ericolin, plus tannins (Millsbaugh

1892, Felter 1922). Although arbutin is effective as a urinary antiseptic, it hydrolyzes to hydroquinone, which is toxic (Foster and Duke 1990).

### *Equisetum*

(From Latin *equus*, horse, and *seta*, bristle)

*Equisetum hyemale*. From Institute of Food and Agricultural Sciences.

*Equisetum hyemale* (of winter, because evergreen)

*biorag* (tusk, Gaelic)

*cañuela* (little cane, Texas, Arizona); *cañutillo [del Llano]* (little cane [of the Plains], New Mexico)

*cuilg struth eich* (horse's water bristles, Gaelic)

Dutch rush (apparently because it was used by the Dutch)

*gijib'inuskori* (it is round, Ojibwa)

[common, greater, rough, winter] horsetail (appearing in the 1200s, from the resemblance of the branched plants to the animal's appendage)  
joint rush

*Kannenkraut* (can herb, German; formerly used to clean milk cans)

*mande idhe shnaha* (*mande*, bow, *idhe*, use, *shnaha*, to smooth, or to make-a-bow-smooth, OmahaPonca); *mi'-he-ga* (Osage)

*nebratah* (said by Rafinesque to be the name among Missouri tribes; similar and perhaps confused with *nibdhathka*, flat river, Omaha, or maybe both were so called)

*pakarut* (Pawnee)

pewter-wort ("Women scowre their pewter and wooden things of the kitchen therewith, which the Germaine women call *Kannenkraut*, and thereupon some of our huswives do call it *Pewter-woort*"; cf. Britten and Holland [1886] 1965)

*prêle* (rush, used since 1538, from *asprele*, in 1200s, based on Latin *asperella*, from the adjective *asper*, rough, from the stem texture, Quebec); *prêle des tourneurs* (scouring rush, Quebec)

*sa-po-tun-a-kio-tio-yis* (jointed water grass, Black-feet)

*Schachtelhalm* (hollow stem, German)

[American, common, great, scrubbing tall] scouring-rush [scouring rush] (applied about 1815, particularly for this species; the reference is to the use of the silicon-containing stems in cleaning or polishing)

shave-grass (akin to scouring-rush)

snakegrass

This widespread species was used throughout the Northern Hemisphere (Foster and Duke 1990). The most common application through the *Equisetum* range is for scouring or sanding because of the silica in the stems.

Leonard Fuchs (1542) mentioned two species known in his time, *E. arvense* and *E. palustre*. These were mentioned by Dioscorides (fl. A.D. 40–80), Galen (A.D. 129–?200), and Pliny (A.D. 23–79) as medical plants, so their tradition in the Old World is venerable. Fuchs listed names for them as English, shavegrasse, horsetayle, water taile; German, *Kannenkraut*, *Katzenwedel* (cat's brush, in the sense of a "voluminous tail"), *Pferdschwantz* (horse muzzle), *Roschschwantz* (horse muzzle), *Roszwadel* (horse muzzle); Dutch, *peersteert* (horse tail, Dutch); French, *queue de cheual* (horse tail), *asprelle* or *presle* (rush); Italian *coda di cauello* (horse tail), *poligono* (many joints), *sanguinaria femina* (for female blood); Spanish, *cien ñudillos yerua* (herb of a hundred little joints). The one name that needs further explanation is *Kannenkraut*. That refers to tin cans used as containers for milk and other items. The cans were cleaned in Germany with *E. arvense* stems due to their high content of silicic acid, the crystals of which show a mechanical cleaning effect (E.Eich and T.Schimming, personal communication, 2003).

Culpeper (1653) made no distinction between the species in Europe, saying that *Equisetum* was "very powerful to stop bleeding either inward or outward... it also stays laxes or fluxes in mañ or woman, and heals the inward ulcers...it solders together the tops of green wounds." He also considered it diuretic and good for curing kidney stones, coughs, and inflammation of the genitals.

The species is remarkable in that no use is mentioned among the people in the southeastern United States. Maybe Porcher (1863) gave some idea of why they are not mentioned when he wrote of *E. laevigatum*: "They contain a great deal of silica. The dried stems of *E. hiemale* and *E. arvense* are imported from Holland for cleaning wooden utensils and polishing cabinet work, turnery, and metallic wares. This plant might be profitably cultivated for the use of turners, cabinet-makers, and other artificers." Indeed,

Gray (1875) says *E. hymale* is from Europe, but later authors say that the European plants are only varieties of the widespread species (Gleason and Cronquist 1963). Plants in the southeastern United States were known as *E. affine* in the 1800s.

The closest neighbors of the Muskogean people recorded as using *Equisetum* were the Cherokee. They used infusions for the kidneys and constipation (Hamel and Chiltoskey 1975). Otherwise, the BellaCoola, Blackfoot, Carrier, Cheyenne, Costanoan, Cowlitz, Cree, Flathead, Gosiute, Havasupai, Hoh, Iroquois, Karok, Klamath, Lakota, Mahuna, Makah, Menomini, Meskwaki, Ojibwa, Okanagan-Coville, Quileute, Quinault, Sanpoil, and Thompson used it for medicine, food, and fibers (King 1984, Moerman 1998). Several of the tribes used the mashed stems to kill vermin and weeds. Winnebago children sometimes made whistles of the stems, but were warned that in blowing them they might call in snakes (Gilmore 1919).

It is now known that the plants contain alkaloids, including nicotine, but their toxicity is due to thiaminase breaking down the vitamin thiamine (Foster and Duke 1990, Mabberley 1997).

### *Eragrostis*

(Greek *eros*, love, *agrostis*, field or country, apparently because it grows widely in cultivated and open areas)

***Eragrostis elliottii*.** Drawn by Edna May Whitehorn. From Hitchcock and Chase 1950.

***Eragrostis elliottii*** (named for American botanist Steven Elliott, 1771–1830)

Elliott's lovegrass (a book name)

love grass [lovegrass] (in use by 1702, when London apothecary James Petiver wrote, "What is peculiar in this Love-grass is its having just under each spike, its stalk clammy," Europe, USA)

tickle grass (because the infructescences "crawl" up inside trouser legs, Kentucky)

*yatlayti: cí* [*yatleititci*] (Mikasuki)

*Eragrostis* is a grass named in 1776 by Nathanael Matthaeus von Wolf (1724–1784). Sereno Watson (1826–1892) named this species in 1890, and the genus contains about 300 temperate and tropical plants. Two of the most famous members of the genus are *E. tef* (t'ef or teff), an important food plant in Ethiopia, and *E. pilosa*, which also produces edible seeds but is best known as being a part of the bricks used to build pyramids in 3359 B.C. (Mabberley 1997).

Although Sturtevant (1955) found no uses, the fact that it has a Miccosukee name suggests a previous use or one that was not shared with him. Indigenous Americans ate the seeds of some species (e.g., *E. mexicana* by Cocopa, *E. secundiflora* by Paiute).

### *Erechtites*

(Greek, from *erechtho*, to rend, break, possibly referring to the dissected leaves; first used by Dioscorides, fl. A.D. 40–80, for some species of groundsel, *Senecio*; another suggestion is that it commemorates Erechtheus, a fabled king of Athens)

***Erechtites hieracifolia*** (having leaves like *Hieracium*, hawkweed)  
*achicoria de cabra* (goat's chicory, Cuba, Puerto Rico)

American burn-weed [burnweed] (the herbs proliferate after disturbance, USA); fire-weed [fireweed] (a name also used for *Epilobium*, USA)

*āsūkitāboe* (stickers, Potawatomi)

*côte soleil* (sun's rib, Haiti)

dog-weed (Bahamas)

*lechuguilla* (lettuce, Dominican Republic)

*leton* (big letter, Haiti)

Paul Hermann (1646–1695) had these plants in cultivation in the Netherlands in 1698. Later, Linnaeus saw them growing at both the *Hortus Cliffortianus* and the *Hortus Upsaliensis*. This herb was called *Senecio hieracifolius* by Linnaeus in 1753. Rafinesque did not think they should be in *Senecio* and created *Erechtites* in 1817. The genus includes 15 American species (Belcher 1956, Vuilleumier 1969, Barkley and Cronquist 1978).

The plant is used as a tonic, an astringent, an alterative, and to treat dysentery (Roig 1945, Liogier 1974).

### *Erigeron*

(From Greek *eri*, early, and *geron*, old man; an ancient name of a Mediterranean plant said by Dioscorides, fl. A.D. 40–80, to be used “because the flowers in spring turn gray like hair”; reapplied by Linnaeus in 1753)

*bakkestjern* (*bakke*, hill, *stjern*, star, Norwegian)

*Berufskraut* (profession weed, German)

farewell-to-summer (Newfoundland, Labrador)

*Feinstrahl* (delicate line, German)

fleabane (“fleabane” first appeared in print in English when Turner published his book *Names of Herbes* in 1548; they were plants to repel fleas)

*impia* (Italian)

*vergerette* (bundle of rods or clothes brush, Quebec); *vergerolle* (French)

***Erigeron annuum*** (living a single year)

*asterana* (from *aster*, star, Italian)

*cespola* (from *cespo*, tuft, Italian)

[little-, tall] daisies (Maine)

[annual, daisy] fleabane (“daisy” was first used about A.D. 1000; however, by Chaucer’s time ca. 1385, it was more recognizable as “daysyes,” now called *Bellis perennis*; subsequently applied to a number of Asteraceae)

lace-buttons

muletail-weed (Oklahoma)

[sweet-]scabious (confusion or comparison with *Knautia arvensis*, *Dipsacaceae*)

***Erigeron annuum***, a. Habit, b. Flower head. c. Disk flower, d. Ray flower, e. Achenes. *Drawn by Regina O. Hughes.*  
From Reed 1971.

white-top [weed] (Ohio)

***Erigeron philadelphicus*** (of Philadelphia)

cocash (English?)

daisy (North Dakota, Ohio)

[daisy, Philadelphia]-fleabane

frost-root [frostroot] (variant of “frost-weed,” used by Porcher in 1863; see *Verbesina*)

mourning-bride (same as “mourning-widow,” North Carolina);  
mourning-widow (“mourning-widow” refers to dark-colored flowers, North Carolina)

scabish [skevish] (comparison or confusion with *Knautia arvensis*,  
Dipsacaceae, Pennsylvania); sweet-scabious (comparison or confusion  
with *Knautia arvensis*, Dipsacaceae)

squaw-weed

***Erigeron pulchellus*** (handsome)

blue spring-daisy

plantain-fleabane (plantain refers to broad leaves)

poor Robin’s plantain (“poor Robin” is a dialectic term in use since the  
time of Chaucer in 1374); Robin’s fleabane (a variant of “poor Robin”)  
rattlesnake-plantain (alluding to use in treating snakebite)

Robert’s-plantain (probably first used by physician Johann D.Schopf  
after visiting North America in 1783–1784; the OED 1971 found it only  
from 1846 and after)

rose-betty

Although William Turner was the first to use the word fleabane for European plants, there is no way to be sure what he was talking about. He wrote, “Coniza maye be called in englishe Flebayne.” Now the name *Conyza* is applied to the American plant *C. canadense* (which see). That plant was introduced into Europe early and was praised by John Parkinson in 1640. At the same time, Parkinson called some plant *C. palustris major*, the “greater Marsh or water Fleabane.” Not long afterward, Culpeper (1653) mentioned two “Marsh fleabanes”—*Erigeron viscosum* and *Senecio vulgaris*.

The practice of using plants to discourage fleas was a long-standing and ongoing practice well before Parkinson. For example, a book on gardening published in 1563 stated, “The Gnats...also be chased away with the decoction of the herbe named Flebane, sprinkled on the bed.” John Gerarde ([1597] 1975) wrote, “Conyza hath from time to time been called English fleabane.” Culpeper (1653) wrote about five kinds of fleabanes—Canada fleabane (*C. canadense*, as *E. canadense*), marsh fleabane (*S.*

*vulgaris*), mountain fleabane (*S. jacobaea*), small fleabane (*P. dysenterica*), and flea-wort (*E. viscosum*), also called marsh fleabane. Europeans had major problems with fleas and used whatever was available to try to rid themselves of the pests. As late as 1801, the New Hampshire American Samuel Stearns said, “the chief use of the *flea banes* is for destroying fleas and gnats, by burning the herbs so as to waste away in smoke” (Vogel 1970).

Moerman (1988) found no indigenous use of *E. annuus*. However, John Bartram wrote of it in 1751, “*Erigeron*, used by some for the bite of a snake: it bears a white flower in the spring, something like a large Daisy, about a foot high, the roots run...of a hot taste; the Indians pound this root, and apply it to cold tumours to dissolve them” (Coffey 1993). Presumably, Bartram was referring to the Delaware near where he lived. Later, the plants were considered diuretic, diaphoretic, and stomachic in edema. They were the source of the pharmaceutical known as *Herba Asteri* (Hocking 1997). During the Civil War, Porcher (1863) said that it was “a favorite diuretic in the dysuria of children—used by Physick and Dewees in painful micturition dependent on nephritis. This also yields a styptic oil similar to that afforded by the *E.Canadense* [*Conyza canadensis*].” *Erigeron annuus* contains tannins and volatile oils (Hocking 1997).

Surely the best known of the fleabanes was *E. philadelphicus*. In the east, it was used by the Cherokee, Houma, Iroquois, Meskwaki, and Ojibwa (Vogel 1970, King 1984, Moerman 1998). Farther west, it was favored by the Blackfoot and Okanagan-Coville.

The Cherokee used *E. philadelphicus* to suppress menstruation, headache, and bleeding, and to promote sweating. It was used for epilepsy, colds, coughs, sores, weak eyes, and kidney problems (Hamel and Chiltoskey 1975). The Houma used it to treat menstruation problems (Speck 1941). The Iroquois made a wash to stop the itch of poison ivy and to cure running sores. They also used it to stop congestion of the lungs (Moerman 1998). The Meskwaki snuffed the powdered flowers to relieve headache, colds, and catarrh by sneezing (Vogel 1970). The Ojibwa not only burned the flowers and inhaled the smoke to make the patient sneeze to relieve head colds, but they also used an infusion to break fevers (Vogel 1970). The Blackfoot made a medicine to stop diarrhea and hemorrhage in childbirth. The Okanagan-Coville used it to relieve headaches.

Physician Benjamin Barton thought in 1804 that *E. philadelphicus* was good “for gouty and gravelly complaints.... It operates powerfully as a diuretic and also as a sudorific.” Rafinesque (1830) found that these herbs “act in a mode peculiar to themselves, by means of their acrid quality. Their oil is so powerful that two or three drops dissolved in alcohol have arrested suddenly uterine hemorrhages.” Porcher (1863) wrote: “It is diuretic, without being offensive to the stomach.... In great repute as a remedy in calculus and in nephritic diseases. It was a favorite prescription in Philadelphia in dropsy, and Dr. Wistar recommends it in hydrothorax complicated with gout.... One ounce of the plant to be administered in infusion or decoction of one pint in twentyfour hours.”

The Cherokee used *E. pulchellus* to suppress menstruation, headache, and bleeding, to promote sweating, and for epilepsy, colds, coughs, sores, weak eyes, and kidney problems (Hamel and Chiltoskey 1975). The Iroquois used a decoction to treat colds, coughs, and tuberculosis (Moerman 1998).

The German physician Johann Schopf wrote in 1788 that “the Robert’s Plantain” was good to treat snakebite because, according to local doctors, it had “many times been of

excellent use where signs of the poison taken up into the blood were already plainly manifest.” He added, “it is raised there foresightfully in gardens, so as to be found in the night if occasion arises” (Coffey 1993). Hocking (1997) considered *E. pulchellus* to be diuretic, diaphoretic, and a tonic.

### *Eriogonum*

(From Greek *erion*, wool, and *gonu*, knee, from the woolly stems and leaves and swollen joints of the stems)

#### *Eriogonum longifolium* (long-leaved)

Indian turnip

long-leaved [wild] buckwheat (“buckwheat” came from the Latin *fagus*, beech, and Greek *pyrum*, fruit or seed, comparing a plant introduced from Asia with one that was native and familiar. The word was recorded in Turner’s *Names of Herbes* in 1548. Turner wrote, “Elatine [*Polygonum esculentum*] is lyke wythwynde, but it hath seedes and floures lyke Buckwheate [*Fagopyrum*]. Buckwheat is cognate with Dutch *boekweit* and German *Buchweize*.)

long-leaved eriogonum (a translation of the Latin)

umbrella-plant (“umbrella” appeared in English about 1611 for the portable shade; it is based on Latin *umbra*, shade; the ribs of the umbrella were first compared to branching in a palm in 1798, and dozens of plants have been associated since)

This genus, related to buckwheat (*Fagopyrum esculentum*) and rhubarb (*Rheum rhubarbarum*), contains about 240 species (Mabberley 1997). *Eriogonum* is endemic to western and southern North America, and some of the species are cultivated for their edible leaves or roots (Diggs et al. 1999). Prospectors believed *Eriogonum ovalifolium* indicated the presence of silver.

The only indications of use of this species are among the Comanche of northwestern Texas and the Kiowa who lived near the Arkansas and Red Rivers of Oklahoma (Moerman 1998). Kiowas ate the roots, and the Comanche took an infusion of them as a remedy for stomach trouble.

In spite of those few records, Moerman (1998) records another 36 species that have been used as foods, chewing gum, dyes, drinking tubes, tobacco pipe stems, brooms, medicines, and toys.

### *Erithalis*

(Named by Patrick Browne, who knew it in Jamaica, from Greek *erithales*, *erithallos*, growing luxuriantly, flourishing)

***Erithalis fruticosa*.** a. Flowering branch, b. Shoot apex with flower-bearing branches, c. Details of flowering branch, d. Flower, from above, e. Flower, longitudinally dissected, f. Floral diagram, g. Fruit. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

***Erithalis fruticosa*** (shrubby)

black-torch (Florida, Bahamas, Puerto Rico, Dominica); *bois chandelle [noir]* ([black] torch tree, Guadeloupe, Martinique, Dominica); [*bois*] *flambeau* (torch [wood], Dutch Antilles, Dominica); *lumbra blancu* (white torch, Dutch Antilles); *tea* (torch, Puerto Rico)

*botoncillo* (little button, Belize)

*cuaba prieta* (black *cuaba*, which may be from *cua*, place, *bana*, large, Taino, Cuba)

*jayajabico* [*jayabico*] (probably Taino, as their name for an unidentified tree is *jayabacaná*, Cuba, Puerto Rico)

parrot-apple (Tobago)

pigeon-berry (Bahamas)

*rompe machete* (machete breaker, Cuba)

*tarro de chivo* (goat horn, Mexico)

*vibona* (Cuba)

Linnaeus described *Erithalis fruticosa* in 1759, putting the species in a genus that Patrick Browne had created in 1756. Ten species are now known in the Caribbean (Mabberley 1977).

Leafy branches are boiled and the decoction used to treat piles, and in a bath for measles and sores. Parched and ground leaves are applied to dry a wound or stop bleeding of a newborn's navel (Ayensu 1981, Morton 1981). The name "black torch" is applied because of the smoke given off when it is burned (Morton 1981). The wood is hard, heavy, and durable, and used for posts and carving. The plant is used in construction, fuel, and medicine in Belize (Balick et al. 2000).

### *Ernode*

(Named by Swartz, Greek, *erno*, a shoot or offshoot)

***Ernodea littoralis*. Drawn by  
P.N.Honychruch.**

***Ernodea littoralis*** (of the seashore)

cough bush (Bahamas)

*ernodea de playa* (beach ernodea)

guana berry (from iguana?, Cayman Islands)

wild cherry (Belize)

yellow jugs (Belize)

Olaf Swartz named the genus and species in his *Nova Genera et Species Plantarum* (New Genera and Species of Plants) of 1788. Nine species are now included in this small genus endemic to the south-eastern United States and the Caribbean (Mabberley 1997).

In the Turks and Caicos and Out Islands the leafy branch tips are made into a tea to treat cough (Morton 1981). Plants are used in Belize for food, for making small items, and as forage (Balick et al. 2000).

***Eryngium*: Kissing Comfits to Rattlesnake Master**

(From *erygein*, diminutive of *eryngos*, to belch, in reference to its carminative properties; a name of a plant, and a goat's beard)

***Eryngium yuccifolium*.** From Britton and Brown 1897.

Europeans were well acquainted with the genus *Eryngium* when they arrived in the New World. In the Old World *E. maritimum* (sea-holly) had been famous since the time of the Greeks, who called it *erungion*. That name was taken into Latin as *eryngion*, and then into Italian and Spanish as *eringio*. Eventually, it made its way into English as “eringos” about the time of Shakespeare.

Dioscorides (fl. A.D. 40–80) prescribed *erungion* for swellings and other people throughout its range collected and used it to the point that it became rare. Now it is prized as a tourist souvenir and threatened with extinction. The species grows throughout all but the coldest parts of Europe near the coasts, and people everywhere knew and used the plants for medicine and food. Candied roots were known in English as either eringos or kissing comfits. By both names, they also had the reputation of being aphrodisiac. In Shakespeare’s *The Merry Wives of Windsor* from 1598, the aging Falstaff has a midnight rendezvous in the park:

*Falstaff*: Who comes here? my doe?

*Mrs. Ford*: Sir John? Art thou there, my deer? my male deer?

*Falstaff*: My doe with the black scut? Let the sky rain potatoes; let it thunder to the tune of Greensleeves; hail kissing comfits and snow eringoes; let there come a tempest of provocation.

Kissing comfits, perfumed and preserved roots of *Eryngium*, usually dipped repeatedly in sugar (Grigson 1986), sweetened the breath—surely needed in a time when toothbrushes were unknown and bathing was considered unhealthy. The word “comfit” is alien to modern English speakers, but it was used from the 1480s through the 1700s, borrowed from Old French *comfiter*. Typically, it meant a preserve made with sugar.

Not only was the Old World *Eryngium* considered to be food, medicine, and an aphrodisiac, but it also was regarded as an alexiteric (antipoison). To the Gaels, *E. maritimum* growing near the ocean was *cuilionn tragha* (*cuilionn*, holly, *tragha*, seashore). With a reputation like that, it is small wonder that Europeans recognized the American *Eryngium* species when they arrived. Two American species were most similar to the Old World plants, *E. aquaticum* and *E. yuccifolium*. Both were used by indigenous people throughout their ranges (Moerman 1998).

Among the most famous uses for these plants was to treat snakebite, particularly from rattlesnakes. While modern people dismiss that application as mere superstition, it must be remembered that Europeans came from a background where members of royalty were regularly dispatched by poisons. Europeans had developed a conviction that certain plants, or other materials, would neutralize poisons. Europeans brought that worldview when they arrived in the Americas. When Europeans found indigenous people believing that certain plants cured bites from poisonous rattlesnakes, they were quick to adopt that same view.

The earliest record of a plant called a snakeroot is from 1635. That was a reference to the Seneca snakeroot (*Polygala senega*), but there were others in which some people had total belief. In 1679, a Mr. Moreau commented that a colleague should “make bold to send a small quantity of snake root, the best sudorific...and the best counter poison that nature ...can afford.” To give an indication of the breadth of that view, there are plants called American snakeroot, black snakeroot, button snakeroot, Canada or Canadian snakeroot, Red River snakeroot, Sampson’s snakeroot, Seneca snakeroot, Texan snakeroot, white snakeroot, wild snakeroot, and Virginia snakeroot.

Immediately, these two new American species of *Eryngium* became known as button-snakeroot, corn snakeroot, and rattlesnake master. Those names apparently were not carried back to the Old World because the plants are known by the French as *panicant d’eau* (water grass [panic or *Panicum*]), and as *Wassermannstreu* (water *Eryngium*) by the Germans. Moreover, even within the United States, distinctive names have evolved. Academics call *E. yuccifolium* the yucca-leaf eryngo. In Louisiana, general knowledge of the plants was lost until a woman named Mary Curby reintroduced the medical applications. From then onward, locals called the plants *merrye-curveye*, their version of the woman’s name (Touchstone 1983).

The American snakeroot names for at least *E. yuccifolium* surely were reinforced, if not prompted, by its name among the Cherokee, who called it *sai kwa* [*silkwa*’yi, *salikwa*’yi] (green snake). Although the Natchez were geographically far away and spoke languages in distant families, they had a name for the plants that seems to be a cognate, *awe’lwaih*. Since the Cherokee and Natchez lived together for some time, they perhaps traded ideas and words occasionally. Former neighbors of the Cherokee, the Koasati, called *Eryngium* either *kowabi* or *hissi tabátka* (*hissi*, hair, *tabátka*, to catch). Those names were of plants questionably identified as *E. aquaticum*, but they came from a period when the differences were not understood (Taylor 1940, Folsom-Dickerson 1965).

*f?âde’*,

Yuchi call button-snakeroot and still take it as medicinal tea during their Green Corn Ceremony (Jackson 2003).

Among the historic Creeks of Georgia, this important plant was *pas's v* (Muskogee). That became *pasa* [pa:ssá] among the Creek-speaking Seminoles and *pasi* among the Mikasuki-speaking Seminoles. Snow and Stans (2001) wrote the words *passv* (Creek) and *pashe* (Mikasuki).

Gideon Lindecum recorded the Choctaw name for *E. yuccifolium* (incorrectly reported as *E. aquaticum*) as *pis-shok*, and *chul-la* (Campbell 1951), comparing the first word to a plant that yielded a red dye. The dye plant is correctly *pishuk* (redroot or *Sanguinaria*), and *chula* means fox. Byington et al. (1915) rendered this *bisakchula*. There is no obvious similarity between the plants so there must be some unrecorded connection. I have to wonder if the correct prefix was not cognate with Creek *passv* and Mikasuki *pashe*, and unrelated to *bissa* (blackberry) or *pishuk* (*Sanguinaria*).

As the ancestors of the Seminoles were pushed farther down the Florida peninsula, they became separated from many of the plants they had used traditionally. *Eryngium aquaticum* was one of those. However, they still had *E. yuccifolium* extending to the tip of the peninsula (*ekan yuksa*, Land's end in Creek). Either that species filled the gap and became even more important to them or was always preferred. Given the importance of *E. yuccifolium* among the people of the southeastern United States, it is tempting to identify the prominent *niye* or *nie* of the Timucua (Gatschet 1877, 1878, 1880) as the same. However, there is insufficient information to be sure. The last syllables of all the indigenous names resemble one another, and may or may not be related.

Millspaugh (1892), Krochmal and Krochmal (1973), and Moerman (1998) all record uses for rattlesnake master. In addition to using it to treat rattlesnake bite, the indigenous people and later American settlers used it against liver problems, as a diuretic, and as an emetic. Chewing the root increases saliva flow. Liquid from roots mashed in cold water was drunk to relieve muscular pains. Roots were used to treat rheumatism, respiratory ailments, kidney trouble, and bladder problems, and to increase perspiration. We know that the plant was used at least among the Cherokee, Creek, Seminole, Meskwaki, and Natchez, and we might assume that it had wider use. This species ranges from New Jersey and Connecticut to Ohio, Wisconsin, Michigan, and Minnesota, south to Kansas, from Texas to Florida and north through the Carolinas. Although not mentioned at all by Gilmore (1919) and not included by Moerman (1998), the fibers from *E. yuccifolium* have been identified as used to make bags found in Arkansas (Swanton 1946) and slippers in Kentucky (Gordon and Keating 2001).

Uses across the indigenous groups were reasonably consistent. For example, the Cherokee used the plants to treat whooping cough, and they rinsed their mouths with an infusion to stop toothache (Hamel and Chiltoskey 1975). The Creeks also used it for respiratory problems and pain (Swanton 1928a, Taylor 1940). They took a cold infusion of roots for neuralgia, kidney trouble, and rheumatism. As it is diuretic, they used it against "the clap." *Eryngium* was also used to treat diseases of the spleen. It was supposed to produce a feeling of peace and tranquillity, and to clean the blood. That may be why it was also used as a "war physic." Several of the early visitors to the Creeks mention the use of this physic. Although he does not mention it by name, Bernard Romans ([1775] 1961) talks at length about the uses of "physics" among the Creeks and their relatives the Choctaw. They used these plant extracts to cleanse the body physically and ritually through their emetic action. One Choctaw who had worked for Romans grew so fond of him that the Choctaw was preparing to go to war against the Creeks when it

was thought that they had killed Romans. Romans ([1775] 1961) wrote: “when I was afterwards missing, and it was thought the Creeks had destroyed us in coming from the Chicasaw nation, this savage armed to avenge my death, and was actually taking the war physick as they term it, when news was brought to the nation of my arrival in Mobile.”

The Meskwaki of Iowa not only considered *Eryngium* an antidote for poison, but they also took it for bladder trouble (Moerman 1998). They used leaves and fruit in their Rattlesnake Medicine song and dance. The Natchez parched the leaves and used them to treat dysentery. They also chewed the leaves and stems to stop nosebleeds (Swanton 1928a).

The Seminoles too had a “Snake Sickness,” which the Miccosukee call *cíntico:binoka:cí:cihcí*: “diamond back rattlesnake [*Crotalus adamanteus*] caused sickness” (Sturtevant 1955). While the name implicates the diamondback, a water moccasin (*Agkistrodon piscivorus*) may also cause the malady. A decoction of *pasí* was applied to the skin that became itchy during that disease. They used the same extract to treat any persistent external sore, or they made a bath of it to treat rheumatism. In addition the Seminoles used *pasí* to treat the “Cow Sickness” (decoction of roots; lower chest pain, digestive disturbances and diarrhea), the “Dead People’s Sickness,” “Menstruation Sickness” (stomachache, headache, body soreness), and “Otter Sickness” (infusion of plants; severe diarrhea, bloody stools, severe stomachache). At least the first three of these maladies required purification and the ceremonial use of this emetic functioned well for that purpose.

*Eryngium aquaticum* is also called rattlesnake master, and it was a popular remedy among the Alabama, Cherokee, Delaware, and Koasati. An infusion was used as an emetic among the Alabama, Cherokee, and Koasati (Taylor 1940). The Delaware used it to expel intestinal worms (Moerman 1998).

*Eryngium yuccifolium* was perhaps the most important plant in the Muskogean pharmacopoeia (Swanton 1928a, Sturtevant 1955, Howard 1984). Alice Snow wrote her observations in her instructions for gathering it: “Look for *passv* in a dry open ground with palmettos around it.... *Passv* blossoms arise on a little stem about two to three feet tall.... To collect the plant, dig it out of the ground to get the roots. Only one root is needed. Sometimes the medicine man asks for a root from a plant that does not have multiple roots, so you have to look carefully. When you look on top, the one with multiple roots will have a lot of heads. The single root will have just one head. The single one is hard to find. Prepare the root according to the doctor’s instructions. The root can be used whole, cut in four pieces, or crushed. I think this is strong medicine because it is the one used for the Green Corn Dance” (Snow and Stans 2001).

### ***Erythrina*: Coral Bean**

(Greek *erythros*, red; flowers and seeds are red in most species)

When Linnaeus created the genus *Erythrina* in 1753, he knew three American species. Now there are 112 species known, with 12 species in Asia, 32 in Africa, and almost 70 in the Americas (Mabberley 1997). Neither Linnaeus nor his predecessors, who had studied these plants in the American wilds, had any idea that they were as important in American cultures as they were. Nor could they have guessed the research

*Erythrina herbacea.* Drawn by  
P.N.Honychurh.

that would go into studying the chemicals in them from the 1930s into the early 1970s (*Erythrina* Symposium 1974, Hargraves et al. 1974).

The research push during World War II began with studies done by the irascible Boris A. Krukoff (1898–1983), one of the few botanists in history to become wealthy. During his study of curare, Krukoff found that *Erythrina* was one of its sources. Then it was discovered that the seeds of some *Erythrina* contain alkaloids with a curare-like action (Dominique and Altamirano 1877 in Symposium 1974, Folkers and Koniuszy 1940 in Symposium 1974). Since curare was an important muscle relaxant during surgery, another source was considered potentially useful. Finally, it was learned that chemicals in *Erythrina* (erythroidine, erysodine) have tertiary bases, not quaternary bases like curare alkaloids, and that they were not as useful as some had hoped.

Further research revealed that *Erythrina* contains many potent chemicals, including more than 30 different alkaloids. The Florida species, *E. herbacea*, contains erysopine, erysopine, erysothiopine, erysothiovine, erysovine, erythrinine, erythroresin, the emetic coraline, erythric acid, and hypaphorine (Standley 1920–1926, Morton 1971, Hargraves et al. 1974, Schmutz and Hamilton 1979).

In the southeastern United States, *E. herbacea* is known as cardinal spear, Cherokee bean, coral bean [plant, tree], and red-cardinal flower. Several of the other names applied to it elsewhere reflect the red color, including *alabarda de cardenal* (cardinal's saddle, Spain), *colorín* (color of life, Tamaulipas to Oaxaca), *corolillo* (little red one), *imortelle* (immortal), and *Korallenstrauch* (coral bush, German). Louisiana is the exception in the United States, where the plants are called cry baby tree and *mamou* (mamma) because the nectar is so abundant the trees “weep.”

*Erythrina herbacea* is sometimes called the eastern coral bean to distinguish it from *E. flabelliformis*, the western coral bean. The southeastern species ranges from the coastal Carolinas to Florida, west to Texas and Arkansas, then in Tamaulipas, San Luis Potosí, Hidalgo, Puebla, Veracruz, Oaxaca, and Chiapas. *Erythrina flabelliformis* grows from Arizona and New Mexico south through Baja California, Sonora, Chihuahua, Sinaloa,

Durango, Zacatecas, Jalisco, Michoacán, San Luis Potosí, Pueblo, and Morelos. *Erythrina americana*, a third species in section *Erythrina* (Krukoff and Barneby 1974), ranges in Mexico from Veracruz to Hidalgo, Mexico, Distrito Federal, Puebla, Chiapas, and Yucatan (García-Mateos et al. 2001). Common names of the three are so intertwined that people may not distinguish among them.

In Mexico, these species have long been intimately tied to daily and religious life. The young flowers are eaten cooked like string beans. I have been told from Chihuahua to Oaxaca that flowers are most commonly cooked and eaten with eggs for breakfast, but they are also recorded as being cooked as a vegetable or used fresh in salads (Morton 1968b). The young leaves can also be cooked and eaten. The flowers are considered pectoral, and the roots sudorific and diaphoretic. Leaves are emmenagogue, and a decoction of the flowers is used to treat pulmonary disorders (Martínez 1969). Juice from the stem is used to treat scorpion stings. The wood is soft and light, and is used for corks, carvings of saints, masks, and similar items. The bark, in addition to giving a yellow dye, is astringent, and it has been used to reduce fever, relieve dysentery, and treat eye inflammation.

In addition, the seeds are used in necklaces, rosaries, and novelties. However, the seeds are poisonous because of the alkaloids they contain, and they have been used for poisoning rats and dogs. Bark and stems have similar properties, and both have been used to poison fish. The beans have been used internally to treat cancer. However, the seeds contain erythroidine, a central nervous system depressant. That depression of the nervous system is surely why they have been used as a hypnotic agent.

Mexicans call the seeds either *colorín*, *patol* (from Náhuatl *patolli*, banner), or sometimes *patol colorín* (red banner, Tamaulipas). Seeds are, or at least were, used in a game resembling dice called *patol*. The Maya name for the seeds was *tze-te* (poison), and the plants are discussed in the Popul Vuh, a text that recounts the origins of those people (Tedlock 1985). The name *tze-te* is usually equated with the Spanish name *árbol de pito*. The Zapotec called these seeds *bi-chilla* [*pi-chijlla*] (*bi*, *pi*, fruit, *chilla*, *chijlla*, luck, oracle) or *bzaa tutze* (*bzaa*, bean, *tutze*, poison). Their red color was synonymous with toxicity among the ancient and modern Zapotecs (Reko 1945). It was these red beans and the game *patol* that the Zapotecs and presumably the Maya and Aztecs used to predict the future. *Pi-chijlla* was also *Cipatli* (the Shark, or the first day of the month) in the Aztec *Tonalamatl* (*tonalli*, ray or sun or sign of nativity, *amatl*, paper), which is the calendar based on divination. To the Zapotec, this deity was *peyoo pichijllo*, the monster of the earth and the symbol of malevolence and of procreation. At the same time, he was the supreme deity (*chijlla-tao*) of the Zapotecs. Therefore, in Mexico, the playing of *patol* was originally no simple game.

Presumably, the names *chijol* and *chilicote* are based on the Zapotec word *chilla* (luck or oracle), and not on *chilli* from Náhuatl. The word *pitos* applied to the flowers literally translated in Spanish means whistle (the instrument). However, the usage looks suspiciously like the word has been derived from some other language, although which is unclear. The word *pito* seems to have been applied to the flowers of *Erythrina* because youngsters make (or at least made) whistles of them.

The Aztecs typically called *Erythrina* species *tzonpantli* [*zumpantle*, *tzompantli*, *tzampantle*, *tzompantle*, *zampantle*, *zumpantle*] (hair-banner, Náhuatl) or *tzonpan-cuahuitl* [*tzan-pan-cuohuitl*, *tzinacnahuaitl*] (hair-banner tree, Náhuatl). The other

Náhuatl name *macayxtli* (*maçati*, become an animal, *ixtli*, powerful) must be associated with the “hypnotic” effect of the seeds. Those seeds were used in communicating with the gods from the Tarahumara of Chihuahua to Guatemala (Schultes and Hoffman 1979). Extracts of one species have been compared to diazepam in calming effects (Garín-Aguilar et al. 2000). Moreover, an array of bioactive chemicals has been extracted from the circum-Caribbean species, including alkaloids and lectins (Hargreaves et al. 1974, Ortega 1990, Naidoo et al. 1997, García-Mateos et al. 1998, 2001, Garín-Aguilar et al. 2000).

In an unsupported statement about *E. herbacea*, Hocking (1997) noted that in the southeastern United States the seeds were “once an item of commerce among Indians.” That statement is all the more fascinating because of the records of medicinal uses among Muskogean people. We have the Choctaw names *chilo’pintobét* (*shilop*, spirit, *in*, its, *tobi*, bean) and *nita inchastoki* (*nita*, bear, *im+chastoki*, its bean). However, other Muskogean said *itco intcastuge* (*icho*, deer, *im +chastoki*, its bean, Alabama), *cointalá:ko* [*ichinchastoki*, *icho inchastoki*] (*eco*, deer, *em*, its, *tvlako*, , bean, Creek), *icó impalaná* (*icó*, deer, *im*, its, *palaná*, bean, Koasati), and *i:ci:salâ:li* (deer’s bean) from the Mikasuki (Bushnell 1909, Swanton 1928a, Taylor 1940, Sturtevant 1955, Sylestine et al. 1993, Kimball 1994). Three of the five have the same translations, but, if Bushnell (1909) gave a literal translation of the Choctaw, they are not cognates to the others. Sturtevant (1955) recorded use of the seeds in the “Horse Sickness,” “Deer Sickness,” and “Dog Sickness.” He added, without elaboration, “mythological food.” Sheehan was told in 1919 that the Seminoles gave it to dogs as an emetic (von Reis and Lipp 1982).

As the horse was a historical addition to the animals in the Americas, the other two illnesses must be more ancient. Moreover, the word for horse in Creek is *coakko* [*corakko*] (big deer), so Horse Sickness must have been derived from the older symptoms and treatment. One of the ingredients in the remedy for Horse Sickness was ground *Erythrina* seeds, either dried or green. At times, scrapings from the roots were dried and powdered as a substitute. This powder was added to some material from other plants, made into a decoction, and ingested. Variations were made for Deer and Dog Sicknesses. Especially because of the statement that *i:ci:salâ:li* was “mythological food,” these surely reflect ancient practices reminiscent of the Mexican uses.

Because *E. herbacea* is not native to Cuba, it is listed as a cultivated substitute for Cuba’s native, *E. corallodendron*. Both species are known as *piñon* (big pine). Still, that name may be an indication of contact with Mexico because *E. corallodendron* is called *piñon de pito*. The word *pito* may have been brought from Mexico to Cuba by the early Spanish.

In spite of Alice Micco Snow’s obvious extensive knowledge of plants used by the Seminoles (Snow and Stans 2001), *Erythrina* is not among those she listed. That absence may reflect shifting knowledge like the comments made about the Seri by Felger and Moser (1985) and about the Mayo by Yetman and Van Devender (2001). *Erythrina* were important plants in a religious context in the past, but they have now become either unimportant or relegated to food or some other secular application.

*Erythronium*

(The Greek name for the purple-flowered European species, from *erythros*, red)

***Erythronium umbilicatum*** (navel-like) (= *Erythronium americanum* misapplied)

adder's tongue (used in the 1580s for the fern *Ophioglossum* in Europe, then applied to other plants)

amber-bell

dimpled trout-lily [troutlily] ("trout-lily" dating from ca. 1898, presumably in reference to the spotted leaves that resemble the fish)

dog's tooth [dog-tooth, dogtooth] violet (used in the 1580s to designate *Erythronium dens-canis*, being a literal translation of the Latin name); *Hundszahn* (hound's tooth, German)

fawn-lily

The Old World *Erythronium dens-canis* corms are a source of starch used for vermicelli and cakes in Japan (Mabberley 1997). Early travelers recorded that they are also eaten with reindeer or cow milk in Mongolia and Siberia, and that the leaves are boiled and eaten (Hedrick 1919). The Dutch herbalist Rembert Dodoens in 1578 and the Englishman John Parkinson in 1609 both listed the plants as ornamental and medicinal in Europe.

The only records found are for *E. americanum*, but given the similarity between these two species and the long confusion, both were probably used similarly. The Cherokee used *E. americanum* only as medicine. They warmed leaves and crushed the juice onto wounds that would not heal, gave an infusion of the root to reduce fever, and made a compound mixture to prevent fainting (Hamel and Chiltoskey 1975). Young Iroquois women took the raw plant, minus the roots, as a contraceptive; they made a poultice of roots for swellings and removing splinters (Moerman 1998).

Winnebago children ate the bulbs of *E. mesochoreum* in the spring (Gilmore 1919). The Blackfoot, Montanan, Okangan-Coville, Okanagon, Shuswap, and Thompson tribes ate *E. grandiflorum* bulbs (Moerman 1998). Kwakiutl ate both *E. oregonum* and *E. revolutum* (Moerman 1998).

Although the bulbs have been eaten fresh and cooked, physicians Jacob Bigelow in 1822 and A. Clapp in 1852 considered them emetic and a substitute for colchicum in treating gout (Millspaugh 1892). Porcher (1863) wrote: "The recent bulbs are emetic when powdered and given in doses of twenty to forty grains. When dried or cooked they become eatable. The berries are said to be more active and certain in their operation than the root." The roots were official in the U.S. Pharmacopoeia from 1820 to 1863, and they were used to treat gout (Vogel 1970). Recent experiments have found that water extracts from *E. americanum* are active against Gram-positive and Gram-negative bacteria; the related *E. grandiflorum* has slight antimutagenic activity (Foster and Duke 1990).

*Eugenia*: Stoppers

(Named for Prince Eugene of Savoy [Eugenio di Savoia, Françoise Eugène de Saavoie-Carignan], 1663–1736)

When I first arrived in Florida, one of the first groups of trees that I studied was the stoppers (*Eugenia*). I was told that there were three possible sources for the common name, which apparently began with Charles S. Sargent in his treatment of North American trees of 1894. As Sargent did not tell how the name stopper came into existence, we have a choice of possible scenarios.

First, the species are hard to pass through where they grow in dense thickets near the coasts. They “stop” a person’s passage, hence the name.

More plausible to some is that the fruits are loaded with tannins and have long served as a remedy for diarrhea. Since they “stop” the problem, they are stoppers.

Unlikely as it is, my favorite explanation was offered by a math professor where I once worked. He was an amateur naturalist and delighted in his ability to tell everyone the names of common trees and shrubs. Since he could rarely tell the stoppers from each other, he was “stopped.”

The genus *Eugenia* was created by Linnaeus in 1753. He accepted the suggestion of John Michell from 1748 who had proposed naming some Brazilian plants after Prince Eugene of Savoy. That prince was, among other things, a teacher of Frederick the Great. However, the plants were named for him because he built the Belvidere Palace near Vienna at the beginning of the 18th century and made a collection of rare plants in its garden. The species Mitchell and Linnaeus used to create the genus name was *E. uniflora*, known as the *pitanga* in Brazil, the *cerezo de Cayena* in Cuba, and the *guinda* in El Salvador. We call it Suriname cherry. This Brazilian species was already widely grown in the 1750s for its edible fruits.

The name stopper is applied in Florida and the Bahamas, with variations being stopper berry (Bahamas), stopper bush (Bahamas), and white stopper (Florida, Bahamas) for *E. axillaris*. The other common species, *E. foetida*, is usually called Spanish stopper (Florida, Bahamas), although it formerly had another common name. In the late 1800s, *E. foetida* was sometimes called “gurgeon stopper.” That modifier comes from French *grugeons*, lumps of crystalline sugar in brown sugar (dating from 1480s), and formerly also meant the smallest or most “writhen” fruit on the tree (first recorded in 1611) and connected with *gruger*, to crunch. “Gurgeon” is no longer used by most English-speaking people, and few even know of the name’s existence.

There are other species of *Eugenia* native to Florida, including redberry stopper (*E. confusa*) and red stopper (*E. rhombea*). These two are rare in the southern end of the state, but they have common names there and elsewhere. Redberry stopper has edible fruits and the wood, which is hard, strong, heavy, close grained, and red-brown, is used for cabinets (Little et al. 1974). In Puerto Rico, it is called *caracolillo* (little snail), *cienequillo* (little swampy one), or simply ironwood (because of the hard wood). In Hispaniola it is *yayao* [*jayao*, *ayay*, *hayao*, *hayay*, *jayayo*], a name also used for *Daphnopsis crassifolia*, Thymeliaceae. *Daphnopsis* has bark with resistant fibers that are used to make strings, but, beyond the common names, there is no indication that *E. confusa* has such bark. The red stopper, *E. rhombea*, is called by the generic name *mije* in Cuba. That may be another Taino word, or perhaps it is a mispronunciation of *myrta*. In

Hispaniola *E. rhombea* is called *arrayán* [*arraiján*] (well-rooted), *bois myrte* (myrtle tree), *escobón blanco* (white broom), *myrte* (myrtle, *Myrtus*), or *tu fais* (you make it). Wood in this species is chestnut colored, durable, hard, strong, and heavy, and is used for cabinets, posts, and stakes, and as fuel (Liogier 1974). Sometimes the flexible stems are used for hanging and drying tobacco.

Many of the common names for *E. axillaris* compare it with cherries, because both have black, edible fruits. Among names making that comparison are black cherry (Jamaica), *merisier pays* (wild cherry, Martinique), *merisier petite feuilles* (small-leaved cherry, Martinique), *merisier* (cherry, St. Barts, Martinique), and *merisier noir* (black cherry, Guadeloupe, Martinique). The name choaky-berry (Dutch Antilles) gives some idea of how unfavorably the fruits of stoppers compare with cherries.

Several other names refer to the edible fruits. The names *grajo* (Cuba, Puerto Rico) and *guairaje* (Cuba) may be words derived from Taino. In Cuba *E. axillaris* is also called *guairaje Colorado* (red *guairaje*), *guairaje macho* (male *guairaje*), *guairaje preto* (black *guairaj* and *guairajón* (big *guairaje*). Elsewhere the fruits are compared with others as in *guayabillo* (little guava, *Psidium guajava*, Mexico, Guatemala), pigeon berry (Dutch Antilles) and strawberry (Caimans). Maybe the name krum berry (Puerto Rico) is related to gurgeon as both refer to dregs.

The wood of *E. axillaris* is hard, heavy, fine textured, dark-red, and strong, and has been used for a variety of items (Small 1933). The Seminoles call the plants *ahikólki* (heartwood? tree, Mikasuki) and the Creek name *hikolwâ* may be a loan-word with the same meaning. Sturtevant (1955) recorded that Seminoles historically used the stems for bows, and they surely used them for other items.

Presumably, the stems have been used as rods because they are called rodwood (Jamaica) or brown-leaf rodwood (Jamaica). Indeed, rodwood is the generic name for *Eugenia* in Jamaica. What use the rods are put to is unstated, but the old saying "spare the rod and spoil the child" comes to mind. Perhaps they also were used historically as ramrods for old muzzle-loading guns. The Seminoles used muzzle-loading guns during the Third Seminole War, and it is likely that they too used the branches of these and other trees as ramrods.

The plants branch freely when the apical bud is damaged and produce a series of small, straight branches. Bundles of those branches have been used for brooms, as noted in the names *escobo* (brush, El Salvador), *escobón Colorado* (red broom, Hispaniola), and *escobón de vara* (broom of sticks, Hispaniola). Although it is a totally different usage, the name wattle (Bahamas, Puerto Rico) indicates another use in building with the long branches.

The hardness of the wood is recorded in names like *guayacán negro* (black lignum vitae, based on the Taino word *guayacán*, El Salvador), *palo de hueso* (bone tree, Hispaniola), and *vaina de espada* (sword's sheath). The wood is valued for "turnery" in Guatemala (Morton 1981), and the young slim trunks are made into rafters to support thatch for roofs. The smaller branches are also used for making fish traps and animal enclosures.

*Eugenia axillaris*, like several others, has been compared with the *chamiso* (also applied, in other areas, to a medicinal grass and to *Ademostoma*, Rosaceae, El Salvador), and the *murta* (myrtle, usually the genus *Myrtus*, Puerto Rico). At least *Eugenia* and *Myrtus* are in the same family and there is a marked resemblance of leaves and flowers.

The sweet, fragrant flowers are recorded in the name *oloroso de San Pedro* (St. Peter's perfume, Cuba), and probably in white bush (Bahamas).

*Eugenia foetida* shares many of these names. It is called *bois petite feuilles* (little leaf tree, Haiti), *escobón* (big broom, Hispaniola), *guairaje* (Cuba), *guairaje blanco* (white guairaje, Cuba), *guairaje Colorado* (red guairaje, Cuba), *guayabillo* (little guava, Cuba), *merisier* (cherry tree, Haiti), *petite feuilles* (little leaf, Haiti), rodwood (Jamaica), and stopper-bush (Bahamas). However, *E. foetida* is called black wattle (Bahamas) to distinguish it from *E. axillaris*. *Eugenia foetida* too has fragrant flowers, and that is surely why it is called *bálsamo* (balsam, Cuba). Because of its hard wood, it is called ironwood (Bahamas). Still, the most anomalous name it has is *malaguette* (Hispaniola). That word is applied to a fiery small chile in Brazil, and there is nothing about this tree that resembles the chile. If the name is based on the locality of Málaga, Spain, it remains an oddity because the tree is native to the Caribbean (see also *Capsicum*: Bird Peppers).

Several stoppers have been used medicinally. Cubans and Bahamians use a decoction of *E. axillaris* to treat colds (Roig 1945, Morton 1981). The plant is boiled alone for tea to treat diarrhea, or with *Bourreria ovata* for building blood and energy. The most widespread use is as a sexual enhancer. According to Ayensu (1981), it is used for "building up men's energy and body." The root is boiled to increase sexual potency, and used in a bath for women, especially after childbirth. With that common use, it seems odd that no common names imply that application.

Spanish stopper is also used in baths, probably much as white stopper. Formerly, the leaves of Spanish stopper were sold fraudulently under the name *Uva ursi* in Havana (Roig 1945).

There is yet another "stopper" in southern Florida that has been the source of confusion from the time of its discovery in the mid-1800s. The plants have been placed in *Eugenia*, *Psidium*, and *Mosiera*. The species first became known in 1854 when it was described as *E. longipes* by Otto Carl Berg (1815–1866). John K.

Small moved it to *Mosiera* in 1933, when he created a new, unique genus for the species. In 1973, Rogers McVaugh moved the species to the genus *Psidium* where Wunderlin (1998) put it, although he was uncomfortable with it being there. Everyone has agreed that the plants did not really "belong" in either *Eugenia* or *Psidium*, but there did not seem to be a good reason to segregate them. Finally, Les R. Landrum (1992) compared them with some Central American species. It then became clear that the Florida plants known as *Mosiera longipes* were members of a Mesoamerican group consisting of three species. Because the plants were disjuncts on the northern fringe of the genus range, they previously had not been connected with their relatives. These plants are called Bahama stopper (Bahamas), mangrove-berry (Florida), and wild guava (Bahamas).

Hedrick (1919) said the fruits of *Mosiera* have "the flavor of cranberries." I consider them to be the best of those plants called stoppers.

### *Eupatorium*

(Named for Mithridates Eupator, 120–63 B.C., king of Parthia [modern northeastern Iran], who used a species as a medicine or as an antidote for poison; he was one of Rome's most formidable opponents)

*Eupatorium serotinum*. a. Lower portion of a plant with roots, b. Upper portion of a plant in flower, c. Flower head, d. Seed. From Buchholtz 1968.

***Eupatorium capillifolium*** (hair-leaved, because of the finely divided leaves)

*copal* (because of a fragrance thought to be similar to the real *copal* or *Bursera*, Cuba)

cypress-weed [cypressweed] (this and *E. compositifolium* commonly appear in prairies around cypress stands when the water is low)

dog fennel [eupatorium] (Florida, Bahamas)

*hinojo de sabana* (savanna fennel; *hinojo* from Latin *feniculum*, Cuba)

*pahí wohoksí* (*pahí*, grass, *wohoksí*, hairy, Koasati)

*taki* [*takri*] (bush, Mikasuki)

*vtako-luste* (*vtakv*, weed, *lvste*, black, Creek; the name was historically applied to an unidentified medicinal shrub with black berries, cf. Martin and Mauldin 2000; and there also may be confusion with *Conyza canadense*)

***Eupatorium compositifolium*** (compound-leaved, alluding to the pinnately divided leaves)

dog fennel

yankee-weed [yankeeweed]

***Eupatorium cuneifolium*** (with wedge-shaped leaves)

waxy thoroughwort (a comparison with *E. perfoliatum*)

***Eupatorium fistulosum*** (tubular, alluding to the stems)

Joe Pye weed (the name “Joe Pye’s weed” was in use by 1818, first for *E. purpureum* and then for other species)  
 queen of the meadow

***Eupatorium hyssopifolium*** (having leaves like hyssop, *Hyssopus officinalis*)

hemp-weed [hempweed]

horehound (compared with the *Marrubium vulgare*, Lamiaceae)

hyssop-leaf thorough wort [hyssopleaf thorough wort, hyssop-leaved thoroughwort] (having leaves like hyssop; see *Bacopa*: Water-Hyssop; because the stem appears to grow “thorough” [through] the leaves)

Justice’s weed (so named because they were used by John Justice of South Carolina in 1800 for curing bites of snakes and other poisonous animals; he received a premium for disclosing his remedy)

***Eupatorium perfoliatum*** (the stem grows through the leaf)

ague-weed [agueweed] (according to physician B.S. Barton in 1810, this is a translation of the plant’s name among northeastern tribes)

[common] boneset (a name applied to comfrey, *Symphytum officinale*, by 1670; applied to these American plants by 1830); wood boneset

cross-wort [crosswort] (Virginia)

fever-wort [feverwort] (North Carolina)

*howe chache* (maybe *hobechechi*, from *hobechi*, steaming, Choctaw; used in sweat baths as an emetic to eliminate “cold and bile”)

Indian-sage (so called because northeastern tribes used it so much to treat ague); wild-sage

Joe-Pye [Joepye] (North Carolina)

*niya* ‘*wibúkúk*’ (Ojibw)

*shauashko* (Choctaw)

sweating plant [weed]

teagel [teasel] (confusion or comparison with teasel, *Dipascus sativus*)

thorough grow [thoroughgrow] (Pennsylvania); thorough wort [thoroughwort, common thoroughwort] (originally “through-wort,” because the stem appears to grow “thorough” [through] the leaves); thorough-stem [thoroughstem, throughstem]; thorough-wax [thorough wax]; thorough-wort [thoroughwort]

vegetable-agrimony

wild-Isaac (maybe named for by Isaac Bierfield, of Newberry, South Carolina, who used “dog fennel” in tanning leather in 1861, cf. Porcher 1863, North Carolina)

***Eupatorium pilosum*** (hairy)

rough boneset

wild horehound (comparison with *Marrubium vulgare*, the European horehound)

***Eupatorium purpureum*** (purple, the flowers)

*amadita'ti* (water dipper, because water can be sucked through the hollow stem, Cherokee)

*caca'bagsit* (piercing leaf stem, Potawatomi)

[Indian] gravel root [gravelroot] (used to expel kidney stones); gravel weed [gravelweed]

*haiyunkpulo* (also applied to an y plant without a particular name, Choctaw)

hemp weed; hemp-agrimony

Joe-Pye weed [jopi weed, green-stemmed, sweet, sweet-scented] (named for Joe-Pye); jopi-root (variant of Joe-Pye, North Carolina)

kidney root (because of diuretic activity); kidney wort [kidneywort]

king of the meadow [prairie]; pride of the meadow; queen of the meadow (Indiana, Maine, Massachusetts); queen of the prairie

knot-root [knotroot]

motherwort (Massachusetts)

purple [tall] boneset

*purpurfärbener Wasserhanf* (purple-colored water hemp, German)

quillwort (were the stems used as ink pens?, West Virginia)

skunk-weed [skunkweed] (from the strong odor); stink-weed [stinkweed]

[purple] thorough-wort [thoroughwort]

trumpet weed [root] (from the hollow stems); turnip-weed (a corruption of trumpet)

*yi'mohkuna'mit'e* (*yi'mohku*, herb, *na'mi*, stinking, Tunica)

***Eupatorium rotundifolium*** (round-leaved)

false horehound

round-leaf thoroughwort [roundleaf thoroughwort]

***Eupatorium semiserratum*** (partly toothed)

small-flower thorough-wort [smallflower thoroughwort]

***Eupatorium serotinum*** (late-flowering)

late eupatorium (a book name)

late-flowering thoroughwort

silver rod

*Eupatorium* is a genus of about 45 species, most of them endemic to the eastern United States (Mabberley 1997). However, there is one famous species native to Europe—*E. cannabinum*. That plant was well known by people in all European countries when the New World was discovered. The herb was an important medicine, particularly in treating “ague” (malaria). Some of the names for it in Europe are *cainb-uisge* (water hemp, Gaelic), *canapa selvatica* (wild hemp, Italian), *eupatoire chanvrine* (hemp eupatorium, French), *eupatório de aveceña* (Avicenna’s eupatorium, Portuguese), hemp-agrimony (compares it with *Cannabis* and *Agrimonia*), *hjorterost* (*hjort*, deer, touched,

Norwegian), *trevo cervino* (deer's three-leaves, Portuguese), and *Wasserdost* (water oregano, German).

When explorers and settlers arrived in the New World, they found a bewildering variety of *Eupatorium* species. However, they soon learned from the indigenous people that these new plants were as important in medicine as the one they knew at home.

There is documentation of use of several species among indigenous tribes. *Eupatorium perfoliatum* was used by the Abnaki, Cherokee, Creek, Delaware, Iroquois, Koasati, Menomini, Meskwaki, Micmac, Mohegan, Nanticoke, Ojibwa, Penobscot, Rappahannock, Seminole, and Shinnecock (Vogel 1970, King 1984, Moerman 1998).

Millspaugh (1892) and Core (1967) speculated that use of *E. perfoliatum* in treating dengue fever (bonebreak fever) resulted in its name boneset. However, that may not be correct. The Abnaki used the herb to "mend bones," and the Iroquois put a poultice on broken bones to help them heal. Williams ([1837] 1962) noted that the Seminoles used it as a gentle emetic and as a sudorific in fevers.

The Cherokee use *E. perfoliatum* as a diuretic, emetic, purgative, sudorific, and tonic, against malaria and sore throat (Hamel and Chiltoskey 1975). John Williams (1827) recorded that the Seminoles made a preparation to treat fevers. Creek women with hip pain were treated with steam from boiling *E. perfoliatum*; those with epilepsy were treated with steam from its roots (Vogel 1970). The Delaware used an infusion of roots and leaves to treat chills, fevers, and stomach problems. The Iroquois used the plants to treat colds, fevers, headaches, kidney problems, pleurisy, pneumonia, stomach problems, syphilitic sores, and to stop the liquor habit. They also considered it laxative. The Koasati and Seminoles used *E. perfoliatum* as an emetic (Taylor 1940, Sturtevant 1955). The Menomini used it in a tea to reduce fever. The Meskwaki gave it to expel intestinal worms. The Micmac recommended it for kidney trouble, gonorrhea, and tuberculosis. The Mohegan took it for relief from colds, especially when mixed with *Prunus virginiana*, to treat fevers and stomach trouble, and as a general tonic. The Nanticoke made a medicine for chills and fever. The Ojibwa used it to correct irregular menses, applied a poultice to help rheumatism pains, and put the chewed plant on rattlesnake bites. The Penobscot used *E. perfoliatum* for gonorrhea, kidney trouble, and tuberculosis. The Penobscot and Rappahannock considered it a tonic. The Shinnecock took it for colds and fevers.

Later people used *E. perfoliatum* much as did the indigenous tribes. Visiting German physician David Schopf called it emetic, purgative, and diaphoretic, and advocated it for arthritis, gout, malaria, and rheumatism in 1788 (Vogel 1970). Settlers used it to combat the yellow fever epidemic of Philadelphia in 1793 (Vogel 1970). Porcher (1863) recommended: "Thoroughwort, drank hot during the cold stage of fever, and cold as a tonic and antiperiodic, is thought by many physicians to be even superior to the Dogwood, Willow, or Poplar, as a substitute for quinine. It is quite sufficient in the management of many of the malarial fevers that will prevail among our troops during the summer; and if it does not supply entirely the place of quinine, will certainly lessen the need for its use." Hocking (1997) listed the herbs as stimulant, tonic, diaphoretic, emetic, and bitter; to be used as a laxative, and to treat fever, malaria, typhoid, yellow fever, dyspepsia, pneumonia, and rheumatism. *Eupatorium perfoliatum* was in the U.S. Pharmacopoeia from 1820 to 1916 and in the National Formulary from 1926 to 1950 (Vogel 1970).

*Eupatorium pilosum* was used by the Cherokee to treat breast problems, tuberculosis, and colds. They considered it diuretic, laxative, and tonic (Hamel and Chiltoskey 1975).

The Cherokee used a hollow stem section of *E. purpureum* to blow medicine onto surfaces. It was also used to treat rheumatism and female problems, as a diuretic and tonic, and to remove sickness from "being near a dead person" (Mooney 1885–1886, Hamel and Chiltoskey 1975). Moerman (1998) said the Mahuna took the roots as a laxative, but Hickman (1993) does not list the species in California. The Meskwaki considered it a breath freshener and men kept it in the mouth when wooing women. The Menomini and Potawatomi used it to stop bleeding after childbirth; the Potawatomi put a poultice on burns; and the Rappahannock made a medicine for the blood (Smith 1933, Moerman 1998). The Ojibwa inhaled the vapors from an infusion made from the tops of the plants to alleviate colds.

Stories vary, but the name Joe Pye weed came from a "Joe Pye," who was either an 18th-century Massachusetts medicine man or a 19th-century Caucasian "Indian theme promoter." He used the root to induce sweating in the treatment of typhus fever (Vogel 1970, Coffey 1993). The rhizome and root (known as purple boneset, gravel root, and queen of the meadow) were listed in the U.S. Pharmacopoeia from 1820 to 1842. These plants are probably most famous as a diuretic (Vogel 1970).

The Alabama took *E. serotinum* to relieve stomach pains (Vogel 1970). The Houma made a decoction of flowers to treat typhoid fever (Speck 1941).

Several other species are known to have been used medicinally in Cuba (Roig 1945). Two common weedy species, *E. capillifolium* and *E. compositifolium*, are notoriously fragrant. Fresh juice from both has been put on insect bites and their herbage has been strewn on floors as an insecticide. Leaves from both have been used to treat arthritis (Hocking 1997). In Cuba, a decoction of *E. capillifolium* is used to stop dysentery and other intestinal problems (Roig 1945). Cubans also consider it hemostatic. *Eupatorium compositifolium* tea made from the roots was considered a remedy for fever (Murphee 1965).

When Thomas Nuttall was ill with "intermittent fever" in Arkansas in 1819, he took *E. cuneifolium*, as *E. perfoliatum* was not available. "This dose, though very nauseous, did not prove sufficient to operate as an emetic, but acted as a diaphoretic and gentle laxative, and prevented the proximate return of the disease" (Nuttall in Vogel 1970).

*Eupatorium fistulosum* has been used for kidney problems in Mississippi. A tea from the plants is said to reduce polyps (Hocking 1997).

Morton (1974) found people in South Carolina using *E. hyssopifolium* to relieve colds and fevers. Local people made a mixture containing these herbs, longleaf pine (*Pinus palustris*), and life everlasting (*Gnaphalium obtusifolium*), which they drank and used in baths. Leaves of *E. hyssopifolium* have been used to treat snakebite in Texas (Hocking 1997).

Porcher (1863) had heard that *E. rotundifolium* had been used to treat consumption. He had no personal experience with the species.

The chemistry of *Eupatorium* is complex and incompletely known. However, several species contain volatile oils. Among these are *E. capillifolium*, *E. serotinum*, and presumably *E. compositifolium* (Hocking 1997). *Eupatorium capillifolium* has phellandrene among those oils (Hocking 1997). Other compounds and bioactivity have been documented. *Eupatorium cuneifolium* contains eupacunin (germacranolide), which

has significant antileukemic and tumor-inhibiting properties (Hocking 1997). *Eupatorium hyssopifolium* contains quercetin 3-glucoside (Wagner et al. 1972). *Eupatorium purpureum* contains euparin and coumarin (Hocking 1997). *Eupatorium rotundifolium* contains glycosides, some of which are tumor-inhibiting sesquiterpene lactones, including eupachlorin and eupatorin acetate (Hocking 1997). *Eupatorium semiserratum* contains antileukemic sesquiterpene lactones, including eupaserrin, in significant amounts. Those lactones inhibit human carcinoma (Hocking 1997).

### *Eustoma*

(Greek *eu*, true, well, *stoma*, mouth, in reference to the showy flowers)

*Eustoma exaltatum* (raised high, lofty) *centaurée maritime* (sea side centaury, an allusion to *Centaurium*, also in the Gentianaceae, French Antilles)

*genciana de la tierra [del país]* (country gentian, Cuba)

[beach, catchfly, marsh, seaside] gentian (Bahamas, Florida)

mountain-bob (Bahamas)

British botanist Richard Anthony Salisbury (1761–1829) named *Eustoma* from plants growing in *The Paradisus Londinensis* of 1806. Later he and

*Eustoma exaltatum*. a. Habit, b. Calyx, c. Petal, d. Stamen, e. Ovary.  
 Drawn by Vivian Frazier. From  
 Correll and Correll 1972.

George Don (1798–1856) moved Linnaeus's *Gentiana exaltata* to create *Eustoma exaltatum*. There are still only three species in the genus, all native to the Americas (Mabberley 1997).

Leaves are steeped in hot water as an eyewash (Ayensu 1981, Morton 1981). The plant, including the roots, is used as a stomachic and febrifuge (Roig 1945).

### *Euthamia*

(Thomas Nuttall said the name was from Greek *eu*, well, and *thamees*, *thameo*, crowded, referring to the flower clusters, cf. Sieren 1981; Diggs et al. 1999 suggested perhaps from *euthemon*, neat or pretty)

*Euthamia graminifolia* (leaves like grass)

flat-top goldenrod

*owesa'wenokûk* (yellow top, Potawatomi)

*Euthamia* is a genus of Asteraceae with eight species confined to North America (Sieren 1981). In the past, some of the species have been placed in *Solidago*, and the common name “goldenrod” indicates the similarity between the genera.

The Ojibwa made an infusion of the roots or flowers to alleviate chest pains associated with lung problems (Moerman 1998). The Potawatomi used blossoms to treat fever (Smith 1933).

Additionally, the plants were used as a hunting lure. The Ojibwa smoked the flowers, believing that the odor simulated that of a deer's hoof.

The plant was considered as a possible rubber source (Mabberley 1997).

### *Evolvulus: Ojitos Azules*

(From Latin *e*, lacking, without, and *volvi*, *volutum*, twining)

One of several names for *Evolvulus alsinoides* in Yucatan is *ojitos azules* (blue eyes). That may not be a Florida name for them, but it certainly beats the “invented” name slender dwarf morning-glory (Wunderlin 1998). Besides, there are so many Spanishspeaking people in Florida that it could be a common name there.

Historically, these diminutive plants had no common name in Florida. The first names for them appeared when floristic biologists felt pressured by amateurs to provide common names. In many parts of the world, *Evolvulus* has common names, and several of the individual species also have them because people use them. However, in Florida, the only member of the genus that has enjoyed a well-known name in recent years is blue daze, *E. glomeratus*. That species was introduced by a nursery in Miami, and the horticultural name invented—much like slender dwarf morning-glory—was created for *E. alsinoides*. These southern Brazilian plants were introduced into horticulture in only about 1979 in Miami, but by the early 1980s they were cultivated throughout the tropics of the world (Austin 1984).

Although there are several members of *Evolvulus* that rival blue daze for beauty of their vegetation or flowers, the group is not well known to temperate residents. Linnaeus even started off misunderstanding them. The species name *alsinoides* (resembling the sandwort, *Alsine*, Caryophyllaceae) was put in *Convolvulus* by Linnaeus in 1753. Linnaeus was prompted to use this species epithet by the last part of *Convolvuli minimi species bisnagarica hirsuta, alsines folio* used by Leonard Plukenet in 1696. Other authors before him used different comparisons. Johannes Burmann, in his study of plants in Ceylon (modern Sri Lanka), compared the herbs with *Anagallis* (Primulaceae). Dutchman Hendrik A. van Rheede, in his *Flora Malabarica*, used the local Indian name *vistnu-clandi*. That Malayalam language name is a variant of the one still used throughout India and nearby Sri Lanka, *vishnu-kranti* (Vishnu's halo, Tamil). The name is gravid with religious and secular meaning and allusion, and it has been used widely throughout the Indian subcontinent for thousands of years (Austin 1980).

The fact that all of the names familiar to Linnaeus in the 1750s were based on Old World collections is one of the incompletely resolved mysteries of biogeography. We have presumed that, because 99 of the 100 or so species in *Evolvulus* are native to the Americas, that all are. One of the two Old World species, *E. nummularius*, was introduced into that hemisphere almost certainly during World War II. In spite of that, the story of *E. alsinoides* is not as clear cut.

According to all studies to date, there is a Sanskrit name for *E. alsinoides*. That name is written *vishnukranta* or *vishnugandi*. Regardless of spelling, both are exactly the same words as *vishnu-kranti* (Watt [1889] 1972, van Valkenburg and Bunyapraphatsara 2001, Parrotta 2001). It is widely agreed that plants with names in Sanskrit are native to the Indian subcontinent. So, how did an American plant come to have a name in Sanskrit, a classical language (relegated to holy texts) that effectively has long been dead?

The conservative answer is that there were some plants used medicinally by pre-European people who spoke Sanskrit, and that the name was switched to the American plants after they were introduced. Such trading of plants and switching of names is well known in the Convolvulaceae (Austin 2000), and surely occurred in other families. Presumably, *E. alsinoides* was introduced into the Old World by the Spanish when they arrived in India about 1505. It is more firmly established that the Spanish introduced sweet potatoes (*Ipomoea batatas*), moonvines (*I. alba*, *I. turbinata*), quamoclit (*I. hederifolia*, *I. quamoclit*), wood rose (*Merremia tuberosa*), and other New World laxative members of the family at about the same time (cf. Austin 1980a,b, 1998). Another blue-flowered morning glory in Asia with American relatives makes the simple answer seem inadequate (Austin et al. 2001), but there is no better hypothesis at the moment.

Regardless of exactly the dates of origins of plants and names in Asia, in the Americas there are multiple names for *E. alsinoides*. In Yucatan, other than being called *ojitos azules*, the plants are known as *sia-siu* [*xia-xiu*, *xiatiu*] (*sian*, enchantment, *xiw*, herb, Maya). This name strongly implies that the herbs had and still have an ancient and religious significance for the advanced Mayan people of Mesoamerica. The Maya also call them *x-havay* [*x-haway*] (leprosy and other contagious skin diseases) and *tsoots ts'ul* (Spaniard hair). The fact that other countries that are occupied by the descendants of the Maya have common names for them further suggests a long history. In El Salvador, they are *cenicito* (little ashy one) or *oreja de ratón* (mouse's ear). In Guatemala, the plants are *quiebra-cajete* (box-breaker), an allusion to medical treatment of bowel problems. In

Honduras, people say *pata de paloma* [*pate paloma*] (dove's foot). Farther north in Mexico and adjacent Texas they are *ojo de víbora* (snake's eye), so maybe people in northern Mexico used them like the Maya.

Throughout the Caribbean, there are also names for these pineland herbs. They are chickweed *evolvulus* (Bahamas) and *ilusión haitiana* (Haitian dream, Hispaniola; the name also applied to introduced and cultivated *E. tents*). The *ilusión haitiana* suggests an application like *sia-siu* or enchantment herb of the Maya. Some compare them with flax (*Linum usatissimum*, Linaceae) by calling them *lin* (flax, Guadeloupe, Martinique). In Cuba, they are *tebenque* (also applied in Oriente Province for *E. arbuscula*).

In South America, *E. alsinoides* is *corre-corre* (run-run, Brazil). Could that name be associated with treating bowel problems? Otherwise, they are *oretama de sabana* [*retama de sabana*] (*retama* of the savana, Venezuela). The name *retama* refers to the European legume *Lygos*, called white broom in English. Some Venezuelans say *Santa Lucía* (St. Lucie). That name also refers to *flor de Santa María*, which is *Chrysanthemum parthenium*, a popular medicine used for eye pains. Alternatively, they are simply a *yerba de sabana* (savana herb, Venezuela).

Indeed, all of these names are reminiscent of the reputation the species has in Asia as a "brain tonic." As such, *E. alsinoides* has been used to treat nervous disability and memory loss (Austin 1980a, Parrotta 2001). Cultured tissues of the plant reputedly accumulate ergot alkaloids, amides of the indole derivative of D-lysergic acid, which is biosynthetically derived from the amino acid tryptophan (Nambiar and Mehta 1981, van Valkenburg and Bunyapraphatsara 2001). However, studies by Eckart Eich (personal communication) failed to find ergoline alkaloids in the species. The German study did, however, find tropane alkaloids (tropan-3 $\beta$ -ol, formerly called tropine), tropan-3 $\beta$ -ol (=pseudotropine), tropan-3-one (=tropinone), merresectine C (an ester of 3 $\Delta$ -tropanol), and other different similar esters of tropanol and nortropanol, respectively, and several pyrrolidine alkaloids (hygrine, norhygrine, 5-(2'-oxopropyl)-hygrine, 5-(2'-hydroxypropyl)-hygrine, 5-(2'-hydroxypropyl)-hygroline, 2',3-*N*-methylpyrrolidinylhygrine, 2',4-*N*-methylpyrrolidinylhygrine, cuscohygrine) (E.Eich, personal communication, September 2003).

While it is dubious that this species produces ergoline compounds, people have independently discovered its impact on human behavior throughout the tropics.

There are a number of other applications of *E. alsinoides* across its range, and several bioactive chemicals have been isolated from it. Other major applications are for gastric distress, duodenal ulcers, and fever, especially in children. Externally, it is applied to promote healing of ulcers (Dey and Das 1988) in Asia, and the Maya too use it to treat skin diseases. *Evolvulus alsinoides* has also been found to contain flavonoids, saponins, triacontane, and sitosterol (Metha and Shah 1958). Laboratory experiments show that alcohol extracts are antiulceric, anticatatonic, and a central nervous system depressant in rats (van Valkenburg and Bunyapraphatsara 2001). In Cuba, a decoction of the whole plant has been used against fevers and chronic diseases of the intestines (Roig 1945). Everyone considers it a bitter tonic and antipyretic.

Linnaeus corrected his mistake of 1753 when he moved the species *alsinoides* from *Convolvulus* to *Evolvulus* in 1762. Indeed, he created the genus for that species and a few others known at the time. Since the 1760s, there has been only one worldwide study of the genus—the doctoral dissertation by Simon J. van Ooststroom (1934). Only a few new

species have been discovered more recently. All of the species are native to the Americas, and range from Canada to Argentina and Chile, with the vast majority of them found in Brazil.

The genus is not well known for medicinal application, although several species contain calystegines (Schimming et al. 1998). The North American endemic *E. nuttallianus* was used by at least the Kakyenta Navajo (Moerman 1998). In addition, the Florida species *E. convolvuloides* and *E. sericeus* are still used in Latin America. Villagers in Salango, coastal Ecuador, told me in 1999 that they make a medicinal tea from *E. convolvuloides* although I have not found it recorded anywhere in the literature. Known as *havay ak* (leprosy vine, Maya), *E. sericeus* is used in Yucatán to treat all kinds of burns (Tapia and Contreras, in press). *Evolvulus arbuscula* grows in the Bahamas, Cuba, Haiti, Jamaica and Little Cayman, and is used by people in all those places (Roig 1945, Morton 1981). A decoction of the entire plant is a popular cure for catarrh and neurasthenia in Cuba. Jamaicans make a tea considered a treatment for heart problems, flatulence, and bellyache. The plants are sometimes sold as a substitute for pencil flower, *Stylosanthes viscosa*. The related Bahamian *E. squamosus* is used in much the same manner, especially against fever or jaundice.

### *Evonymus*

(Sometimes spelled *Euonymus*; ancient Greek name, from *eu*, good, *onoma*, name; *Euonymus* was the mother of the Furies, an appropriate allusion, as the plants had a bad reputation for poisoning cattle)

***Evonymus atropurpureus*.** From Sargent 1905.

*berrétta da prète* (priest's cap, from the four-lobed capsule, which resembles the shape of the priests' hats in the first half of the 19th century, Italian)

*bonetero* (little hat, Spanish)

burning-bush (a common name applied by the 1880s to a number of plants having red flowers or fruits because they reminded people of the biblical story in Exodus III)

*corallini* (little red one, Italian)

*feóras* (Gaelic)

*fusaggine* (little spindle, derived from Latin *fuscus*, Italian); *fusain* (from Latin *fusaginem*, through *fusago*, derived from Latin *fuscus*, a spindle, for spinning thread, because of the hard wood used in the manufacture of spindles, French); *fusaria comune* (common spindle, Italian)

*oir* (Gaelic)

prick-timber (“The butchers doe make skewers of it, because it doth not taint the meate as other wood doe,” Aubrey 1626–1697 in Vickery 1995)

*Spindelstrauch* (spindle shrub, German); *spolebush* (spool bush, Norway)

***Evonymus americanus*** (of America)

burning-bush

bursting-heart; hearts-bursting-with-love

[American] strawberry bush [American strawberrybush] (applied since 1856 or before because the fruits resemble those of strawberry, but only in their red color)

***Evonymus atropurpureus*** (dark purple)

arrowwood; Indian-arrow [root, wood]

bitter-oak

bleeding-heart

*bonnet de pretre* (priest’s hat, Quebec)

burning-bush

*fusain* (spindle, Quebec)

*ni-ni’-ba zhon* (*ni-ni’-ba*, pipe stem, *zhon*, wood, Osage)

spindle-tree

strawberry-tree

[eastern] wahoo [wa-a-hoo, wagoon] (Dakota)

*wahú*, literally, arrowwood, first used ca. 1810; however, see also

*Ulmus*)

*wananha-i-monthin* (ghost walking-stick, OmahaPonca)

Although physician E.P.Claus said in 1861 that the indigenous Americans introduced the early settlers to *Evonymus* as a medicine, many of them also knew of its use from the Old World (Linnaeus [1749] 1979, Millspaugh 1892). Old World people formerly used the wood to make gunpowder, skewers, spindles, and toothpicks (Dwelly 1933). They also made purple and yellow dyes from the seeds and other parts. Mabberley (1997) said that the wood was used to make “violin bows (pegwood),” but bows have no pegs.

The two eastern species were used similarly, but not identically by different people. *Evonymus americanus* was used by the Cherokee in an infusion to relieve stomachache, spitting blood, and a prolapsed uterus, and in a mixture to treat urinary problems and venereal disease. They also put an astringent infusion as an antiseptic on swellings and other skin problems, and sniffed bark infusions for sinus trouble (Hamel and Chiltoskey

1975). The Iroquois used a decoction to either suppress or stimulate menstruation and to treat difficult urination (Moerman 1998).

The Meskwaki put a decoction of *E. atropurpureus* bark on sores that were slow to heal and used a bark infusion to treat sore eyes (Vogel 1970). The Mohegans used a leaf infusion as a physic (Vogel 1970). Winnebago women drank a decoction of the inner bark of *E. atropurpureus* to cure uterine trouble (Gilmore 1919).

Porcher (1863) wrote that both species were “[e]metic, discutient, and antisyphilitic. It is also thought to be narcotic. The seeds are said to be nauseous, purgative, and emetic, and are used in some places to destroy vermin in the hair. Leaves are poisonous to cattle.”

Lampe and McCann (1985) say that only *E. europaeus* has been recorded as containing the poisons, although Foster and Duke (1990) consider the American species as probably dangerous. That Old World species contains evomonoside, a digitalis-like cardioactive glycoside, several alkaloids but mostly evonine, and a compound that inhibits protein synthesis (Foster and Caras 1994).

*Evonymus atropurpurea* contains a resin called euonymin, the alkaloid evonymol, evonysterol, and evatromonoside (which is a cardiac glycoside digitoxigenin and arabinose) (Hocking 1997, Diggs 1999). Wahoo was in the U.S. Pharmacopoeia from 1863 to 1916 and in the National Formulary from 1916 to 1947 (Vogel 1970). The root is a bitter tonic, laxative, increases bile flow, and stimulates the liver (Hocking 1997).

### ***Exostema*: Princewood**

(Greek *exo*, outside, *stemma*, crown or wreath, referring to the exserted stamens)

***Exostemma caribaeum*.** a. Branch with flowers and fruits, b. Node,

showing stipule and insertion of leaves and flower buds. c. Young flower, side view. d. Flower at anthesis, side view. e. Flower tube longitudinally dissected, f. Floral diagram, g. Fruits dehiscent.

*Drawn by Priscilla Fawcett. From Correll and Correll 1982.*

Forests in southern Florida, especially MiamiDade and Monroe Counties, are composed largely of West Indian plants. Locally these forests are called hammocks, and they approach having 100% tropical species composition. Visit these forests in the peak mosquito season, and you may have an opportunity to see flowers of one of the state's rarest trees—if you survive the blood loss.

Arrive early in the morning and you will smell the fragrant vanilla odor and see the white flowers on prince wood (Florida, Bahamas, Puerto Rico). Scientifically these trees are *Exostema caribaeum*, and they were first introduced to Europeans in 1760. That year Nicolaus Jacquin published his book *Enumeratio Systematica Plantarum* (Systematic Enumeration of Plants) where he called the tree *Cinchona caribaea* (the Carib's quinine). His reason for thinking it was a quinine was supported by two lines of evidence—the plants resemble *Cinchona*, and local people throughout the Caribbean call them quinine in their languages, and use them to treat malaria. It was not until 1819 when the Swiss Johann J. Roemer (1763–1819) and the Austrian Josef A. Schultes (1773–1831) revised the eighth edition of Linnaeus's *Systema Vegetabilium* that it was realized the species belonged to another genus in the family Rubiaceae. They moved the species to a genus created by Aimé J. A. Bonpland (1755–1858), the exploring companion of Alexander von Humboldt (1769–1859). In 1807, Bonpland created *Exostema*. In case you have seen more than one spelling or author citation of that genus be aware that its synonyms are *Exostemma* Augustin-Pyramus de Candolle and *Exostemon* George Edward Post and Carl E. Otto Kuntze (Lorence 1999).

We now know that *Exostema* is more closely related to *Chiococca* than to *Cinchona* (Bremer and Jansen 1991). However, there are compounds in *Exostema* that show *in vitro* activity against the organisms that cause malaria (Noster and Kraus 1990, Kohler et al. 2001). So, while they did not become famous for it, the indigenous people of the Caribbean discovered effective medicines against this killer disease as did those of South America who showed Europeans the source of quinine. History has made much of the multiple ways that humans combated malaria in the Old World (Desowitz 1987), but it has given short shrift to similar activity in the Americas.

Many common names still reflect the use to treat one of the most deadly diseases of the tropics. Among those names are Caribee bark tree (Jamaica), Caribbean princewood (Florida), *falsa quina* (fake quinine, Mexico), Jamaica Jesuit bark (Jamaica), *polo de quina* (quinine tree, Puerto Rico), *piñi-piñi* (maybe a variant of *quinquina*, Dominican Republic), princewood (Florida, Bahamas, Puerto Rico), *quina* (quinine, Hispaniola, Puerto Rico, Dominica), *quina caribea* (Carib's quinine, Cuba), *quina criolla* (creole quinine, Dominican Republic), *quina de las Antillas* (Antillean quinine, Cuba), *quinina* (quinine, Hispaniola), *quinina des Antilles* (Antillean quinine, Hispaniola), *quina de*

*Michoacán* (Michoacán quinine, Mexico), *quinquina bord de mer* (seaside quinine, Guadeloupe, Martinique), *quinquina des caraïbes* [*quenquine caraïbe*, *quinquina caraïbe*] (Carib quinine, Haiti, Guadeloupe, Martinique), *quinquina pays* (wild [country] quinine, Haiti), *quinquina pit on* (wild [mountain peak] quinine, Martinique), and West Indian quinine bark (Puerto Rico). Note that some names compare the trees to “Jesuit’s bark,” one of the old names for the quinine source. We do not know what the Caribs called this species, but they said *utáuaho* for the related *E. sanctae-luciae*. A similar word probably was used for *E. caribaeum*.

Treating malaria is not the only medicinal application for the plants. The bark is also emetic (Mexico) and, combined with leaves, has been used to treat colds and improve the appetite (Virgin Islands), and as an antipyretic (Morton 1981). Moreover, *Exostema* has been used as a fish poison (Virgin Islands). Wood with the bark removed is steeped or boiled and taken for stomachache, diarrhea, and piles, and given to children as a vermifuge (Bahamas). To treat these problems, the bark may be combined with *Picramnia pentandra*. Otherwise, the bark may be boiled with mahogany (*Swietenia mahagoni*) to make a tea believed to prevent anemia.

The plants contain a number of chemicals that may be effective against some or all of those complaints. *Exostema* contains coumarins, 4-phenylcoumarin, antineoplastic agents, and cucurbitacins (Mata et al. 1987, 1988, 1990, Noster and Kraus 1990, Bose and Banerji 1991, Calera et al. 1996, Kohler et al. 2001). Pharmacological assays of the bark and roots show antibiotic activity and depression of the central nervous system.

Most of the other common names applied to these trees allude to their use as torches. Probably the most obvious of these are black torch (Virgin Islands), *bois chandelle* (candle tree, Guadeloupe, Martinique), *bois flambeau* (flame tree, Guadeloupe, Martinique), *chandelle Anglais* (English candle, Haiti), princetorch (Bahamas), and yellow torch (Puerto Rico, Virgin Islands). Less obvious in use for light sources are the names *cera amarillo* (yellow wax, Cuba), *cerillo* (little wax tree, Cuba), *cerillo de costa* (coastal little wax tree), *cerillo de loma* (hill wax tree), and *tendre en gomme* (soft gum, Guadeloupe, Martinique).

Surely associated with the light source and a pleasant smell are *copalche* (literally, copal tree, Chiapas, Oaxaca), *copalchi de Jojutla* (copal tree from Jojutla, Morelos), *copalchi de Michoacán* (copal tree from Michoacán, Mexico), *jocotillo de cerro* (mountain plum, Chiapas), *chaktsiis* [*chactsus*] (*chak*, red, *ts’ix’*, resin, Maya, Yucatan), and *sabac-ché* [*sabakche*] (*sabak*, black spot, *ché*, tree, because the resin, when exposed to the air, turns black, Maya, Yucatan). However, several of these names suggest use of the resins for other purposes. The comparison with *copalche* alludes to the previous mixture of three species that were exported to Europe under that name. The other two species were *Coultarea hexandra* (Rubiaceae) and *Croton niveus* (Euphorbiaceae). All had bark with a similar odor and flavor, and all were used to treat intermittent fevers of malaria (Uphof 1968).

The other names seem to be comparisons; some are obvious and some are not. Names like *albarillo* (little apricot, Puerto Rico) and *poirier de montagne* (mountain pear, French Antilles) must refer to the general plant or leaf aspect because the fruits are dry capsules.

This species is called *carey* (Cuba) or *carey de costa* (coastal *carey*, Cuba). Other references using the word *carey* are *frutica de carey* (*Bourreria succulenta*) and *carey de costa* (*Krugiodendron ferreum*). Technically, the Taino word *carey* refers to the sea turtle

(*Caretta caretta*) and the comparison between these plants and that animal is not immediately apparent. However, the polished wood of all of these is the saffron-like color that resembles the turtle shell, especially if polished. If there is another allusion, it is not obvious. Ironwood (Antigua) certainly notes that the wood is hard, heavy (specific gravity of 1.0), and strong. Maybe *macagua de costa* (coastal *macagua*, Cuba) is based on another Taino word.

If these names allude to the wood, it is because the wood has been used by many people. Modern use is predominantly for fence posts, but that surely was not the only pre-European application (Liogier 1974). Throughout its range the wood is used in cabinets, canes, and inlaid pieces (Standley 1920–1926, Liogier 1974). The wood must have been used in buildings and for other purposes, especially because we know that the Caribs used the related species *E. sanctae-luciae* to make paddles (Nicolson 1991).

Several of the common names refer to the aromatic white flowers. The blossoms are nocturnal, and that is further suggested by the comparison with jasmine (*Jasminum*, Oleaceae) in the name *palo de jazmín* (jasmine tree, Puerto Rico). The names *lechisillo* (little milky one, Puerto Rico), *lirio bobo* (fool's lily, Dominican Republic), and *lirio santana* (Santa Ana's lily, Cuba) also seem to refer to the milky white, lily-like flowers.

The comparisons with *hesito* (hesitation?, Nicaragua) and *cuero de sapo* (toad skin, Puerto Rico) completely elude me.

### *Exothea*

(From Greek, *exoteros*, outside, expel, because the genus was removed from *Melicoccus*)

*Exothea paniculata*. Drawn by  
P.N.Honychurch.

***Exothea paniculata*** (having paniculate inflorescences)

bitter bough (Bahamas); butter bough (a corruption?, Florida, Bahamas)

*bois mûlct* (mullet tree, Haiti)

*cuerno de buey* (ox neck, Dominican Republic)

*gaita* (Puerto Rico)

*guacarán* (*guacara*, lie, Taino, Puerto Rico)

*guamacá* (probably Taino, Cuba)

*guénépier* [*quénépier*] *mañ on* (wild genip tree, Haiti); wild genip (“genip” arose through confusion with *Genipa americana*, which is *jenipapo* in Portuguese from Tupí *ñandi’pá*; later applied to *Melicoccus bijugatus*, Jamaica; leaves on *Exothea* somewhat resemble those of *Melicoccus*)

inkwood (Florida)

*nisperillo* (little *nispero* [*Manilkara zap o da*], Dominican Republic)

white ironwood (Puerto Rico)

*yaicuaje* (probably Taino, Cuba)

Scottish botanist James Macfadyen (1798 [1800?]- 1850) described *Exothea* in *The Flora of Jamaica* of 1837. In 1888, German botanist Ludwig Adolph Timotheus Radlkofer (1829-1927) moved Jussieu’s *Melicocca paniculata* to create *Exothea paniculata*. Two other species have been added to the genus from the Caribbean and Central America (Mabberley 1997).

The wood is reddish, hard, compact, and used for posts, railroad ties, marine piling, boat building, cabinets, and tool handles (Liogier 1974, Little et al. 1974). Historically, ink was made from fruits, hence the name “inkwood.”

# F

## *Fagus*

(*Fagus*, classical Latin name of the beech tree; Greek *phagos*, to eat, an allusion to the edible nuts; akin to Akkadian *paglu*, strong)

***Fagus grandiflora*.** From Sargent  
1905.

beech [bóece, béce, beche, bech, beetch, beeche] (derived from Old Teutonic *bokjon*, about A.D. 800, originally meaning a tree with an edible fruit; Old Teutonic *boka* was cognate to Latin *fagus*, and Greek *phagos*); *bech* (by Turner [1548] 1965); *beuk* (Dutch); *boc* (Old English); *boek* (Flemish); *bøk* (Norwegian); *bók* (Old Norse); *Buche* (from Old Teutonic *boka*, German; cognate to “book,” because the earliest writing tablets were made from beech bark and boards)

*faggio* (from Latin *fagus*, Italian); *faidhbhile* (Gaelic); *fayard* (from 1371, used only in the dialect of Lyon, derived from *fagus*, French); *feagha* (Gaelic); *haya* (Spanish)

*hêtre* (from Frankish *haistr*, from the radical *haisi* bush, or thicket, French)

mast-beech (Culpeper 1653)

***Fagus grandifolia*** (large leaved)

*ajawe'mic* (Potawatomi); *ajawêmij* (Ojibwa); *popsquawsewaymeysee* (Shawnee, cf. Edgar 1891); *schauweminschi* (*minschi*, plant, Delaware)

[American, red, ridge, stone, white, winter] beech

beechnut (said to be first used in 1739)

*hatombalaha* [*hatomalaha*] (Choctaw); *toomalàaha* (Alabama)

*haya* (Hidalgo)

*hêtre [américain, rouge]* ([American, red] beech, Quebec)  
*jozgóera* (Onondaga)  
*nofó* (Koasati)  
*tanicaní* (Delaware)  
*totocal* (Hidalgo)  
*tukse'* ? (beech tree, Catawba)

Europeans knew *Fagus sylvatica* when they arrived in the New World. They used the straight-grained wood for kitchen utensils, turnery, and furniture (Mabberley 1997, de Cleene and Lejeune 2002). The wood contains toxic saponins and formerly was a source of creosote. Moreover, since prehistoric times the edible seeds ("nuts") had been used for human food. Their oldest name in Greek simply means "to eat." People later began calling them "beechnuts" or simply "mast," a term that includes acorns (Davidson 1999). According to Sargent (1905), the sweet seeds "are a favorite food of swine, and yield a valuable oil." He further recorded that, for *F. grandifolia*, "the sweet nuts are gathered and sold in the markets of Canada and of some of the western and middle states."

In France, the term *fou* (or *fayard*, or *fayar*) was used to designate large trees left for reproduction (and beech nuts?), while *hêtre* was used for young trunks repeatedly cut and regrown with multiple stems, as in a copse (Bloch and von Wartburg 1994). Later, as forest management changed, *hêtre* was used for the adult tree as well as the coppice growth.

The American beech produces prized wood, although so few stands remain that mature trees are uncommon. Along with birch (*Betula*) and maple (*Acer*) it has been used in the hardwood distillation industry for charcoal, wood alcohol, and acetate of lime (Harrar and Harrar 1946). Wood has been sold commercially in the United States for making brush backs, chairs, clothespins, cooperage, crates, flooring, fuel, shoe lasts, spools, spoons, tool handles, toys, and veneers (Harrar and Harrar 1946, Vines 1977). As a fuel, it has few superiors, making an excellent cooking fire when thoroughly dry (Harrar and Harrar 1946). Seeds have been sold in the northern states and Canada to make vegetable oil and as swine food (Vines 1977).

The Cherokee used the wood for lumber and buttons (Hamel and Chiltoskey 1975), while the Micmac made snowshoe frames from it (Moerman 1998). The Potawatomi carved it into bowls (Smith 1933, King 1984). Surely all tribes used it as fuel.

Indigenous people in the New World also made use of the edible fruits. The Algonquin, Iroquois, Menomini, Ojibwa, and Potawatomi are known to have eaten the seeds, but probably all the people within the range of the species ate them (Smith 1933, Yanovsky 1939, Moerman 1998). Sometimes the nuts were eaten mainly by people working in the bush. Others gathered and stored them. They sought out caches left by chipmunks (*Tamias straitus*) or deer mice (*Peromyscus*) because it was known that they stored only sound seeds and it saved a great deal of work. Sometimes the seeds were crushed and boiled and the liquid used as a nourishing drink. At other times, they mixed the nuts with cornmeal and beans or berries to make into bread as they did with chestnuts, hickory nuts, and acorns. Oil was rendered from them as from chestnuts, hickory nuts, and acorns. The Iroquois mixed the oil with bear grease as a mosquito repellent and used it for a hair tonic (Moerman 1998).

There were also medicinal applications of *Fagus*. The Cherokee chewed the nuts to expel worms (Hamel and Chiltoskey 1975). The Iroquois used the bark when women were having difficulties with abortions (Moerman 1998). The Iroquois also used the trees in a "blood purifying" mixture; decoctions were used to treat burns or scalds, for yellow skin and gall, and to treat tuberculosis (Moerman 1998). Similarly, the Malecite used the leaves on sores. The Menomini mixed the bark and root in medicines, and the Micmac treated skin problems with leaves. The Ojibwa made a medicine for pulmonary problems. The Potawatomi treated burns and scalds, and restored frostbitten extremities with leaves (Smith 1933). The Rappahannock made a bark infusion to treat poison ivy (Vogel 1970). Extracts from the trees contain guaiacol (Hocking 1997).

### ***Ficus*: Strangler Fig**

(*Ficus*, the old Latin name of the tree or fruit; akin to Akkadian *piqu* or *siqu*, narrow, *piaqum*, *siaqum*, to be narrow; Greek *sykon*)

In 1895, W.D.Collier, who lived on Key Marco in southwestern Florida, was digging muck from shell ridges on his property for his garden. Buried within the muck he found pieces of wood, cords, and shell implements. After preliminary visits by an amateur archaeologist, and by personnel from the Bureau of American Ethnology in Washington, D.C., an expedition was arranged to excavate the site. The project was headed by Frank Hamilton Cushing of the bureau, and resulted in what were the most remarkable plant artifacts yet discovered in Florida. Nets made of palm leaf fibers, carvings of animals, household utensils, and ceremonial masks had been preserved in the anaerobic conditions of the marine peat and muck deposits.

***Ficus*. *Ficus aurea* . Note sessile figs.  
Drawn by P.N.Honychurch. *Ficus***

*citrifolia*, a. Leafy branch with figs. Note stalked figs. b. Leaf outline, c to e. Development of growing branch tip; c. Resting bud, d. Growing bud. e. Growing bud with stipule removed, f. Young fig pair. g. Young pistillate flowers, one on left with expanded style, h. Long-styled pistillate flower, one on right longitudinally dissected, i to k. Staminate flowers, i. Same age as pistillate in g and h, j, ripe, k, in anthesis. l. Fig in vertical section with wasp grubs hatching, seeds ripe. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

Among the artifacts recovered was a bivalve molluscan shell (genus *Macrocallista*) with the figure of a male masked dancer drawn on the inner surface. That image is the only known self-portrait of the Calusa people, who had inhabited the site until about A.D. 1500. Studies done at the Smithsonian Institution Bureau of American Ethnology concluded that the image was created with the latex of a native fig (Gilliland 1975). Exactly how white latex became the black image of the dancer has not been explained, but presumably, the latex was used as an adhesive to retain black pigments (probably charcoal) on the shell surface. We do not know how much more the preEuropean Glades people used figs. However, judging from the uses by the Seminoles and other people within the range of the species, their utilization was considerably more diverse than just artwork.

By the time Sturtevant (1955) worked with the Seminoles, he found that they used at least *Ficus aurea*. To the Miccosukee this tree was *hacaló:pí* [*hachelope*], and their relatives the Creeks said *hilokwapí* [*hilokhaga*]. Those terms, based on *vlokpíctv*, mean “sticks to you,” although Sturtevant (1955) considered them simple. Both people ate the fruits, used the stems for arrows, made bowstrings of the bark on the roots, and used the same kinds of strings (*hapalch aske*, Mikasuki) for lashing house parts together, stringing up meat, and fish lines.

They used the latex as a chewing gum, and the plant figures prominently in their medicine to heal wounds and cuts. Martin and Mauldin (2000) called the tree *helokhkv*, and said the bark was beaten to extract the gum for chewing. The bark was then mashed and applied to wounds. The Creeks were also recorded as boiling bark of the root in water, and wrapping the sore with a bandage soaked in the medicine. Yet another record is of the chewed berries used as a “bandage” for the wound.

Since the Seminoles ate the fruits of *F. citrifolia* and used its latex as chewing gum, they probably used it in the same ways. At least the Cuna of Panama used *F. citrifolia* as a bandage to help wounds heal (Duke 1968), so the practice using both species was

widespread. Indeed, Hernández, writing in 1651, noted that *F. petiolaris* was similarly used in Mexico. He recorded that “its milk cures sores of the lips and chronic ulcers” (Standley 1920–1926).

Figs of various kinds have been important in the lives of people wherever they occur. Europeans were well acquainted with one kind of fig when they arrived in the New World. That species was *F. carica*, the cultivated fig called *higo* (Spanish), *figue* (French), *fico* (Italian), *figo* (Portuguese), and *Feige* (German). Those names are derived from the Latin *ficus*, while the Greeks say *sykon*. Even Gaelic *fige* was based on the Latin root. The origin of the cultivated European species is disputed, with some contending that it came from southwestern Asian (Mabberley 1997) and others maintaining that it evolved in the Caspian region of northwestern Turkey (Zohary 1982). Regardless, it was in the Gezer site, on the western slopes of the Judean mountains, by 5000 B.C. (Zohary 1982), and the fruit was known to the Hebrews as *teenim*. However, when Europeans arrived in the American tropics, they found trees that awed them. Oviedo ([1526] 1969) was so taken with the size of a fig that he not only spent a page talking about it, but also included a drawing.

The Spanish were not always complimentary about the New World figs. The general term for most of those was *matapalo* (tree killer). The name not only is used in Spanish-speaking areas, but also remains in English-speaking areas such as Trinidad. Another name that conveys the contempt that people feel for these trees is Scotch attorney (Trinidad). Usually, however, in English we simply say strangler fig. To distinguish species, modifiers are added, like Florida strangler fig (Florida), golden fig (Florida), or golden wild fig (Florida, Bahamas). These names refer to *F. aurea*, and emphasize its red fruits. Sometimes English speakers simply say rubber tree (Florida) or wild fig (Florida to Panama).

Elsewhere the plants are known as *figuier* (fig tree Haiti, Guadeloupe, Martinique), *figuier blanc* (white fig, Haiti, Puerto Rico, French Antilles), *higo* (Panama), *higo cimarrón* (wild fig, Dominican Republic), and *jagüey hembra* (female fig, Cuba). The word *jagüey* is another of those Caribbean terms whose origin may be Taino.

Within Florida, trees of *F. aurea* range about halfway up the peninsula. They reach the Cape Canaveral area on the east coast and the Tampa Bay region on the west. When there are periodic freezes, they are sometimes killed to the ground, but rarely are the roots destroyed.

It may be this species that Williams ([1837] 1962) called “howey.” That name has not been found elsewhere, but his description seems to fit. He wrote: “This tree bears a multitude of little figs, not bigger than a grain of corn. They are of a dark brown colour when ripe. In formation and taste, they are perfect figs.”

The more tropical of the two native species in Florida is *F. citrifolia*. This species is typically restricted to the southern four counties (Broward, Collier, Monroe, Miami-Dade). During warm periods, it extends its range northward, as it has into southern Palm Beach County since the 1970s. Cold periods in the past have driven it back into the tropical parts of the peninsula. *Ficus citrifolia* also has the larger range of the two, being found from Belize, Yucatan, Florida, the Bahamas, Cuba, Hispaniola, Jamaica, and the Lesser Antilles to Paraguay. On the island of Barbados, it is known as the bearded fig. It has been suggested that Barbados (bearded) is derived from the earlier frequency of these fig trees (Goodding et al. 1965). This species too is basically called fig, with names based

on that word including *figuier blanc* (white fig, Guadeloupe, Martinique), *figuier maudit* (accursed fig, Guadeloupe, Martinique), *higo* (fig, Dominican Republic), *higuerón* (big fig tree, Colombia, Darien), *higuillo* (little fig, Hispaniola), and short-leaved wild fig (Bahamas).

To distinguish it from *F. aurea*, it is sometimes called *jagüey macho* (Puerto Rico). But, in Puerto Rico, it is also *jagüey* or *jigüerillo*. Names alluding to the latex include *bois laglu* (the glue tree, Puerto Rico), *caucho menudito* (little rubber tree, Colombia), and *lechecillo* (little milky one, Puerto Rico). In Panama, it is either *saguagua* (Cuna) or *tugua* (Choco), but usually to the Cuna, it is *suu* [*tuu*]. In Guadeloupe and Martinique it is the *aralie-cerise* (joining cherry), presumably an allusion to the fused adventitious roots.

In the Bahamas and some other parts of the Caribbean, fig latex dissolved in water is taken for heartburn, palpitations, and chest pains (Morton 1981). In Hispaniola, the latex is used on hernias and for chest diseases (Liogier 1974). The latex contains ficin, a proteolytic enzyme, but what impact that would have on those problems is unclear. However, studies have shown that extracts from other *Ficus* species are antibacterial, anti-inflammatory, analgesic, antipyretic, and antidyenteric (Atique et al. 1985, Dey and Das 1988, Macfoy and Cline 1990, Mousa et al. 1994, Forestieri et al. 1996). The latex is chewed throughout the range of figs, and used at least by children as a birdlime to catch birds. Like the Seminoles, people in Hispaniola use the adventitious roots as cords.

Figs were more important to Mexican cultures than to those in the Caribbean. One of the widely used names for fig trees is *ornate* (*amatl*, paper, Náhuatl). This may be applied to the tree, or some variant of *macahuite* (*ama-cuahuitl*, fig-tree) may be used. Not only was that done by the Aztecs, but the same also applied to the Zapotecs. In their language, the fig is *guiichi be-yo* [*quichi pe-yo*] (*guiichi*, paper, *be-yo*, fig tree, Oaxaca). As in Náhuatl, paper has the same name as the tree. Even the Tarascan name *siranda* (paper) is applied to fig trees. Figs for making paper were so important that there are places named after them, including *Amatepec* (hill of figs) and *Amecameca* (place where they wear fig shirts). However, the Aztecs also called them *coamichin* (*coatl*, snake + *michin*, fish, fish-snake or eel), probably because of adventitious roots. From that is derived the common name *camichin*.

Paper made from figs held special importance to the Aztecs and other people in Mexico. Bark preparation into paper was associated with curing and religion. Therefore, not long after the arrival of the Catholics, this practice mostly went underground. However, before it disappeared, a few of the texts that were in Aztec libraries were preserved. Not only did Mexicans use the paper "books" to record histories, but they were also used in correspondence among the elite. A common use that survives involves paper for *brujería* (witchcraft), where images of people, horses, and other animals are fashioned from the sheets. The images (*muñecos*) are employed in curing diseases, or buried in front of a house or corral for malevolent purposes. The use continues among the Otomí people of Puebla who cut out figures of the *nahuales*, their devils and spirits (Standley 1920–1926). *Amate* paper also is still being produced in Guerrero where it is brightly decorated with scenes of everyday life (Sandved et al. 1993). These bright sheets of paper not only depict modern village life, but also provide a glimpse into history that extends back for thousands of years of papermaking.

### *Flaveria*

(Frenchman A.L.de Jussieu named the genus in 1789, with Latin *flavus*, yellow, referring to a yellow dye obtained from *Flaveria chilensis*)

***Flaveria bidentis*** (having two teeth)

*contra erva do Peru* (Peruvian antipoison, Brazil); *contrayerba* (antipoison, Chile, Peru?)

*dasdaqui* (Chile); *daudá* (Chile)

*matagusanos* (worm-killer, Chile)

smelter's bush; *smelterbossie* (smelter's bush, South Africa)

***Flaveria trinervia*** (three-veins, meaning the three large veins of the leaves)

*contrayerba* (antipoison, Cuba)

*yerba de la vieja* (old woman's herb, Cuba)

This small genus of 21 species is confined to the Americas except for one endemic to Australia and two that are pantropical (Powell 1978, Mabberley 1997). Presumably, *Flaveria bidentis* is one of the widespread species because it has names in both Afrikaans and English in South Africa (Quattrocchi 1999).

In Argentina, Brazil, Chile, and Peru, an infusion of *F. bidentis* has been used to treat indigestion, as an aromatic, stimulant, and vermifuge. Externally the herb has been used as a cataplasm for bites of poisonous animals and washing wounds (Hocking 1997).

Roig (1945) found that people in Cuba, especially in the Province of Havana, used *F. trinervia* to treat intestinal problems including gastroenteritis. Others considered *contrayerba* effective in treating the kidneys or diarrhea. The plants are also used as a medicine in Belize (Balick et al. 2000).

### *Forestiera*

(Named by Jean Louis Marie Poiret for 19th-century French physician Charles Leforestier)

***Forestiera segregata*.** a. Pair of leaves with an axillary male inflorescence, b. Node with male inflorescence, unexpanded. c. Male inflorescence, flowers expanded, d. Staminate flowers, two stages, e. Diagram of male inflorescence. f. Diagrammatic arrangement of leaves and buds at node. g. Female inflorescences, h. Pistillate flowers, side view, i. Pistillate flowers, longitudinally dissected, j. Floral diagram of pistillate flower, k. Diagram of female inflorescence. l. Twig with fruits. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

***Forestiera segregata*** (kept apart)  
blueberry (Bahamas)

Florida privet (Florida, Bahamas)

ink-bush (Bahamas, Virgin Islands)

*okfi:li* (Mikasuki); *oyak tó:ska* [*oyakró:ska*] (Creek)

*yanilla blanca* (white little *yana*, comparing it to *Conocarpus erectus*, Taino, Cuba)

Jacquin named plants he found in the Caribbean *Myrica segregata* in 1788. Then, in 1810, Poirer described *Forestiera*, and in 1893 Jacquin's species was moved there. This North American genus now contains 15 species (Mabberley 1997).

The straight stems of *okfi:li* were formerly used as arrows (Sturtevant 1955). The name "blueberry" probably simply notes the color of the fruits and does not make a comparison with *Vaccinium*. "Inkbush" suggests that ink may have been made from the fruits in the past.

### *Fragaria*

(From the Latin *fragans*, sweet-smelling, from the fragrance of the fruit; classical name of the strawberry)

***Fragaria virginiana*.** From Britton and Brown 1897.

*eerdtbesycruyt* (earth berry herb, Dutch in 1542); *aardbei* (earth berry, Dutch); *eertbesien* (earth berry, Belgian); *Erdberre* [*Erdber*] (earth berry, German)

*fragola* (written *fragharia* in 1542, then as *fraghe fragole* in 1571, reaching modern form by 1696, Italian); *fraisier* [*fraysier*] (first written as *fresa* by Ruellius in 1536, then as *frayses*, but the modern form did not appear as *fraise* until 1542, Quebec, France); *freizen* (Dutch); *fresa* (Spanish)

*jordbaer* (field berry, Norwegian)

*morango* (from Latin *morus*, the mulberry, so have been derived from a popular Latin *moranicu*, which may have come from *terrestria mora*, earth mulberry, from the 1400s, Portuguese)

strawberry [strawberrie, strayberry] (Anglo-Saxon *streowberie*, a name applied with variable spelling since about A.D. 1000; but in modern fashion since Turner in 1538; the element "straw" has been thought to come from a particle or straw or mote, alluding to the achenes on the surface of the fruit; another view is that it denotes the runners)

*sùbh thalmhainn* (*sùbh*, strawberry, *thalmhainn*, of the earth, Gaelic);  
*sùbhag làir* [*sùbh làir*] (*sùbhag*, strawberry, *làir*, mare, Gaelic)  
*tlachd sneisd* (*tlachd*, beauty, *sneisd*, little, Gaelic)

***Fragaria virginiana*** (of Virginia)

*aʔni* (Cherokee)

*aparu-huradu* (*aparu*, berry, *huradu*, ground, Pawnee)

*a'stepa'x kotka* (*asi*, berry, Biloxi)

*ba-stse'-ga* (Osage); *bashte* (Omaha-Ponca); *haz-shchek* (*haz*, fruit, Winnebago); *wazhushtecha* (*wazhushtecha sha wi*; from *sha*, red, *wi*, moon [June], when strawberries are ripe; *wazhushtecha-hu*, the plant, Dakota)

*biun̄ko* (Choctaw); *biyyo'ka* (Chickasaw); *biyyo- khá* [*obi:yokhá*] (Koasati)

*cokake'nict li'l* (soft blackberry, Atakapa)

*idziaze* (little heart, Chipewyan, Canada); *i'n dzheah* (Slave, Canada)

*kepalv* [*kepáv*] (Muskogee)

*maskihkiwimin* (recorded by Strachey in [1612] 1953 as *muskeskiwimins*, Powhatan, Virginia); *mskihkawimin* (Penobscot, Maine; derived from Penobscot *mskihko*, which is cognate with Cree *maskihkiy*, Fox *maskihkiwi*, Menomini *maskihkiw*, Ojibwa, *maskikki*, all meaning herb)

*odeiminidjibik* (*ode'i*, heart, *mini*, berry, *dji'bik* root, Ojibwa); *otahimin* (heart berry, Cree)

*otquechtarocu òchia* (Onondaga)

scarlet Virginian strawberry (Porcher 1863); [mountain, scarlet, Virginia, wild] strawberry

*wtèhim* (Delaware); *wuttahimneash* (New England tribes fide Hedrick 1919, surely Algonquian)

In 1542, Fuchs found several names in use for the common European strawberry, *F. vesca* (Meyer et al. 1999). Most of them carried over into the names applied now.

Fuchs wrote that the juice of the plants with honey was good for the spleen. Added to white pepper it helped breathing difficulties. The fruit quenches thirst and is good for the stomach, especially if it is bilious. Juice pressed from the plant is good for face sores, red eyes, and excessive tears. Root decoctions soothe liver problems, settle the stomach, and staunch menstrual flow, while it firms the gums, soothes mouth ulcers, and makes the breath sweet (Meyer et al. 1999).

Fruits on the European plants were good, but not as good as those discovered in the New World. *Fragaria virginiana* is one of the two species (the other is *F. chiloensis*) involved in the hybrid now cultivated around the world. In 1643, Roger Williams (1603?– 1683), who founded the Rhode Island colony, wrote that he heard a physician say, “God could have made, but God never did make, a better berry” (Williams in Hedrick 1919).

Fruits of *F. virginiana* were food to at least the Abenaki, Algonquin, Bella-Coola, Blackfoot, Cherokee, Cheyenne, Clallam, Cree, Dakota, Haisla, Hanaksiala, Hesquiat,

Iroquois, Kitasoo, Klamath, Menomini, Meskwaki, Nespelem, Nitinaht, Ojibwa, Okanagan-Coville, Omaha, Osage, Oweekeno, Pawnee, Ponca, Salish, Sanipol, Shuswap, Thompson, and Winnebago (Gilmore 1919, Densmore 1928, Yanovsky 1936, Hunter [1823] 1973, Moerman 1998). Where other species grew, they too were eaten. Gilmore (1919), speaking of the tribes of the Missouri River, summed up the common theme when he wrote, "All the tribes were fond of wild strawberries and luxuriated in them in their season, but the fruit was too juicy to lend itself to the process of drying successfully for winter use." Moerman (1998) listed a few exceptions to that, but most people ate them raw or cooked. When sugar became plentiful, indigenous people began making jams and jellies from them. *Fragaria* was so appreciated by the Iroquois that the fruits were considered symbolic of their deities' beneficence and used in the Strawberry Thanksgiving ceremony (Moerman 1998). The Dakota considered June the "red moon" because strawberries were ripe (Gilmore 1919).

Medicines were also made from strawberries, much like those applied by Europeans. The Blackfoot used a decoction to stop diarrhea. The Cherokee used an infusion to treat dysentery, kidney and bladder diseases, visceral obstructions, jaundice, and scurvy, and to calm the nerves. They also thought that having strawberries in the home insured happiness—a view modern people certainly share (Hamel and Chiltoskey 1975). The Iroquois ate the fruits as a spring medicine. The Malecite and Micmac took an infusion of the plants to regulate menstruation. The Ojibwa used them to stop diarrhea in children and to treat stomachache. To heal sores, the Okanagan-Coville mixed deer fat with powdered leaves and put the powder into babies' mouths to cure thrush. The Thompson people also used them to stop diarrhea (Moerman 1998).

Porcher (1863) wrote, of *F. vesca*: "[Conrad] Gesner [in 1587] speaks of the good effects of the fruit in calculous disorders, and Linnaeus extols its efficacy in gout, having, he says, prevented paroxysms of it in himself by partaking of this fruit very freely. They are also supposed to possess vermifuge properties, and to be useful in phthisis [tuberculosis]. The leaves are astringent and are recommended for bowel complaints; and the roots are much used in Europe as diuretics; frequently given in dysuria, in infusion, made with an ounce to the pint of water.... Lallemand...states that strawberries are quite serviceable in relieving irritable conditions of the bladder and urethra."

Of *F. virginiana*, Porcher (1863) said: "It was introduced into England in 1629, and possessed a fame equal to the hautbois. The pulp has a fine flavor. ... This plant is well known, and its economical value and application require no description. The use of the fruit often acts beneficially upon dyspeptics, who are benefited by acids. The celebrated [French painter, Henri-Julien-Félix] Rousseau [1844–1910] was always relieved of a calculous affection by eating this fruit.... The old Carolina strawberry is a well known and much esteemed variety. The pulp is colored and juicy, and has a fine vinous flavor." The first record of the new strawberry in England was by John Parkinson, and that was only 8 years after Edward Winslow found them in Massachusetts (Hedrick 1919).

### *Fraxinus*

(The classical Latin name for the tree and a spear or javelin made from it; akin to Akkadian *burasu*, Hebrew *beros*)

***Fraxinus caroliniana*.** Drawn by Vivian Frazier. From Correll and Correll 1972.

*a'gimak'* (snowshoe wood, Ojibwa); *pachgámmak* (Delaware)

ash [aesc, asse, aycha, assche, asche, ashe, aish, esche, ach] (from about A.D. 700, with the alternate spellings in chronological order; in the 1440s the German and English spellings were identical); *ask* (Norwegian); *ask-oz* (Old Teutonic); *askr* (Old Norse); *es* [esc, esk, eisce, essce] (Dutch); *Esche* (German)

*do:-tsu* (Cherokee); *gahuwéja* (Onondaga)

*frassino* (Italian); *freixo* (Portuguese); *fresno* (Spanish); *frêne* (French)

*nuin* [nion] (Gaelic, also the 12th letter of their alphabet)

*wat* (Atakapa)

***Fraxinus americana*** (of America)

[American, Biltmore, Biltmore white, Canadian, cane, small-seed white, white] ash

*eto-hv'tke* [to hvtkv] (*eto*, tree, *hv'tke*, white, Muskogee)

*franc frêne* (“*frêne*” from Latin *Fraxinus*, after having gone through *fraisne*, then *fresne*, the circumflex often indicates a lost “s”; anything with *franc* in Canada refers to an imported European species, since they are so commonly planted in France, so “imported ash,” Quebec); *fresno* (Texas)

*itcika wanat* (*itcika'*, bow, *wanat*=?, Catawba); *yap tukse* (tree river bank, Catawba); *wactu'* (Catawba)

*shinap* (Choctaw); *sinapo* (always applied to this species, and sometimes to other *Fraxinus*, Alabama); *sinapó* (Koasati)

***Fraxinus caroliniana*** (of Carolina)

[Carolina, swamp, water] ash

*eto hvtke* [*etchatka, tohatka*] (*eto*, tree, *hvtke*, white, Creek, Muskogee); *hikaape* (*hik*, white?, *aape*, stem or trunk, Mikasuki)  
pop-ash [poppy-ash]

***Fraxinus pennsylvanica*** (of Pennsylvania)

[green, pumpkin, red, river, swamp, water] ash

*emkwansûk* (spoon wood, Potawatomi); *mealawqua* (Shawnee, fide Edgar 1891)

*frêne rouge* (red ash, Quebec)

*kiditako* (Pawnee)

*psehtin* (Dakota); *tashnánga-hi* (*hi*, plant, OmahaPonca)

According to Norse legend, the world tree, an evergreen ash called *Yggdrasill*, overshadows the whole universe. Its roots, trunk, and branches bind together Heaven, Earth, and the Netherworld. Rooted in the primordial abyss Hel, the subterranean source of matter, it bears three stems. The center stem runs up through Midgard, the earth, which it supports. It issues out of the mountain Asgard where the gods assemble at the base of Valhalla. This heaven can only be reached by Bifrost, the bridge of the rainbow. The stem spreads its branches over the entire sky, the leaves are the clouds, and the fruits the stars. Four stags, Dain, Dvali, Duneyr, and Durathor, symbolizing the cardinal winds, live in these branches, feeding on the flower buds and dripping dew from their antlers to earth. The second stem springs up in Muspellsheim, the warm South, where Urth, the Past, Verdandi, Present, and Skuld, the Future, dwell, and the gods sit in judgment. The third stem rises in Niflheim, the cold North, where all knowledge of mankind flows from the fountain of the Frost-giant, Mimir, the personification of Wisdom. The tree is the Nordic Tree of Life, symbol of strength and vigor, because the first Norseman, Ask, sprang from the ash tree (Lehner and Lehner 1960, de Cleene and Lejeune 2002).

The green ash (*Fraxinus pennsylvanica*) is also one of the two sacred trees to the Omaha; the other is the cedar (*Juniperus virginiana*). The *tashnánga-hi* is connected with the beneficent natural world, and part of the sacred pole of the Omaha and Ponca is made of it; the other part is cottonwood (*Populus*).

White ash (*F. americana*) wood was used to make handles for fishing spears by the Ojibwa, and the Micmac used it to make ax and knife handles (Moerman 1998). The Abenaki used it for snowshoe frames; the Iroquois for baskets and chair backs; and the Malecite for boat frames and snowshoes. The Meskwaki also used it to weave baskets, and the Ojibwa to frame snowshoes (Moerman 1998).

*Fraxinus americana* has long been an important timber tree; it has constituted 40% of the “ash” wood sold in the United States (Vines 1977). The wood has been used for butter tubs, cabinets, doors, farm utensils, frame parts for airplanes, fuel, millwork, musical instruments, railroad cars, railroad cross ties, refrigerators, sashes, silos, tanks, toys, vehicle parts, veneer, and woodenware (Vines 1977).

People from Maine and nearby Canada south to the Cherokee (Moerman 1998) made medicines with it. The Abenaki used an infusion of the bark to induce menses. The Iroquois used it as a physic, especially to purify the blood chewed bark to induce vomiting, or drank an infusion to stop stomach cramps. They used it as a laxative, and a compound mixture was used to become pregnant. Externally, the Iroquois used a bark

infusion to treat syphilitic and neck sores (Moerman 1998). The Meskwaki put an infusion of bark on sores, itch, and vermin in the scalp. The Micmac used leaves to clean after childbirth, as did the Penobscot. The Ojibwa made a bark medicine for several problems. White ash bark was official in the National Formulary from 1916 to 1926 for use as a tonic and astringent (Vogel 1970).

Both the Iroquois and Meskwaki considered the leaves of the tree effective against snakebite. The Iroquois used a bark infusion to treat snakebite. The Meskwaki also used a decoction of flowers to treat snakebite.

Perhaps southeastern tribes believed the same because of the comments by Porcher (1863). He wrote: "The leaves of the *F. Americana* are said to be so highly offensive to the rattlesnake that that formidable reptile is never found on land where it grows; and it is the practice of hunters and others having occasion to traverse the woods in the summer months to stuff their boots or shoes with white ash leaves as a preventive of the bite of the rattlesnake." However, the belief that ash repels snakes is ancient in Europe (de Cleece and Lejeune 2002).

Popash (*F. carolinianum*) is not mentioned by Moerman (1998). However, Bennett (1997) found the Miccosukee using the stems to make pestles, *sofkee* spoons, and for firewood. Historically, they used the branches to make bows and arrows. The bark can be cut where the plant has been damaged and used to make "women's medicine."

Green ash (*F. pennsylvanica*) wood was used by the Cherokee, Cheyenne, Dakota, Havasupai, Lakota, Ojibwa, Omaha, Pawnee, Ponca, Potawatomi, and Winnebago. From it they made ball bats, baskets, butter paddles, cradle board, firewood, handles for hoes, axes, and other utensils, lumber, poles—especially for the Cheyenne Sundance Lodge—racks for drying meat, snowshoe frames, sleds, spoons, tent poles, pegs, and pins. It was most widely prized for making bows and arrows and for pipe stems (Moerman 1998). Whites use the wood for tool handles, furniture, interior finishing, cooperage, and wagons (Vines 1977).

There is less on medicine regarding this species, with records from the Algonquin, Ojibwa, and Omaha. The inner bark was made into an infusion to treat depression. It served as a tonic and was used in a number of rituals.

The Ojibwa even cooked and ate the inner bark of *F. pennsylvanica* (Yanovsky 1936). Supposedly, it tasted like eggs (Moerman 1998).

# G

## *Galactia*

(Named by Patrick Browne, from Greek *galaktos*, milk, presumably because some species contain milky sap)

***Galactia volubilis*.** Drawn by  
*P.N.Honychurch.*

***Galactia volubilis*** (twining)

*hilishifi* (good medicine, Mikasuki); *ayikchi: fi* (maybe from *heleswa*,  
medicine, [here], good, Creek)  
milk-pea

Linnaeus ([1753] 1957) seems to have had considerable problems with the twining legumes. This species he called *Hedysarum volubile*. Patrick Browne studied the plants in Jamaica, and named the genus *Galactia* in 1756. It was not until 1894 that New York botanist Nathaniel Lord Britton (1854–1934) moved the Linnaean species into *Galactia*. Since then the genus has grown to 140 species found mostly in the Americas and Australia (Mabberley 1997).

The Seminoles use the roots of milk-pea in “Baby Sickness,” “Cow Creek Sickness,” and in childbirth, against appetite loss, fever, headache, and diarrhea (Sturtevant 1955).

*Galium*

(From Greek *gala*, milk, alluding to the European *G. verum*, whose flowers were used to curdle milk for cheese making or to color cheese; early Christian tradition had it that *Galium* filled the manger in Bethlehem)

***Galium aparine*.** a. Habit, b. Enlarged node with leaf whorl and lateral inflorescences, c. Flowers, top view and side view, d. Fruits. *Drawn by Regina O. Hughes. From Reed 1971.*

***Galium aparine*** (an old generic name, interpreted as meaning to catch, cling, or scratch)

*amor del ortelano* (garden love, Spanish from 1542)

*aparine* (clinging, Italian, from 1542)

*aspergula* [*asperula*] (rough, 1542 pharmaceutical name); *aspérule* (French)

*caille-lait* [*gaillet*] (curdle milk, Quebec)

catchweed bedstraw ("bedstraw," since ca. 1527 applied to these plants because they resembled straw that was formerly used to stuff mattresses; originally applied to one species, *Galium verum*, Our Lady's Bedstraw, and later as a generic name)

cheese-rennet (English in 1653)

[spring] cleavers [clyver, clevers] (from Old English *clife*, Old High German *chliba*, from root of *clifian*, to stick, adhere); *cleefscruyt* (cling herb, Dutch, from 1542)

*cu-chullain* (*cu*, dog, *chullain*, reed, Gaelic)

*garbh-lus* [*lús garbh*] (*garbh*, rough, *lús*, herb, Gaelic)

goosegrass [goose grasse, goosegrass cleavers] (since at least 1538 applied to this species and others because branches were used to feed geese)

goosshareth (English, from 1542)

*grateron* [*gratteron*] (scratches first used 1314, is still used in the west, influenced by *gratter*, to scratch; from *gleteron*, derived from old French *gleton*, from *cleton*, originally Frankish *kletto*; akin to German *Klette*, the name is used for plants that grab or hook, French)

*Klebkraut* (cling herb, from 1542, German)

*Labkraut* (rennet herb, from 1542, German; formerly used in making cheese)

lady's bedstraw; *bedstro* (Dutch); *Liebfrauenstroh* (*Liebfrau* refers to "unsere liebe Frau," our beloved mother, Mary, mother of Christ, *Stroh*, straw, German)

*luibh-an-ladhair* (*luibh*, herb, *an*, of the, *ladhair*, claw, Gaelic)

*nan isht hummachi* (*nan*, a thing, *isht*, for, *hummachi*, dyeing red, Choctaw)

sticky bobs [willy, stickywilly]

sweethearts

***Galium circaezans*** (resembling *Circaea*, "enchanter's nightshade")

[forest, licorice, woods] bedstraw

cross-clover

wild licorice

***Galium tinctorium*** (used for dyeing) dye [stiff, marsh] bedstraw

***Galium triflorum*** (three-flowered)

fragrant [sweet-scented] bedstraw

lady's bouquet

*wau-inu-makan* (woman's medicine, OmahaPonca)

*wau-pezh* (woman's herb; *wau*, woman, OmahaPonca)

***Galium uniflorum*** (single-flowered)

oneflower bedstraw (a book name)

Europeans certainly knew *Galium aparine* when they arrived in the New World as the species is native to all parts of Europe. Many consider it not native to the New World, but in either case its history sets the stage for the others that are native here for certain.

Lady's bedstraw contains coumarin, at least in the dried form, and has been used to treat a variety of maladies, including bladder and kidney inflammations, dropsy, kidney

stones, and fevers (Foster and Duke 1990). The juice contains citric acid, which may have antitumor activity. In addition, some think the plant lowers blood pressure. It is known to contain asperuloside, an anti-inflammatory compound (Foster and Duke 1990). Juice is used to prevent scurvy, but may cause contact dermatitis. Culpeper (1653) praised it highly.

Moreover, lady's bedstraw was the source of important dyes (Cannon and Cannon 2003). It was used to color Scottish tartans, and in several countries, to color cheeses. Yellow dyes come from the flower tops, while the roots yield red. The tops with different mordants can yield a range of colors from yellow and green to orange and brown. Colors from roots are coral-reds to salmon-pinks, and they withstand light and washing without fading. Roots contain several anthraquinones including alizarin, purpuroxanthin, rubiadin, purpurin, and lucidin. According to Cannon and Cannon (2003), most species in *Galium* contain these pigments.

Apparently the only records of Muskogean people using *Galium* are the Choctaw who used *G. triflorum* (reported as *G. asperellum*), *G. pilosum* (reported as *G. boreale*) (neither in Florida), and *G. uniflorum*. They took both *G. triflorum* and *G. uniflorum* as an astringent, to treat the flu, and "in all cases requiring diuretic, and diaphoretic" (Campbell 1951). *Galium pilosum* was used to prevent pregnancy.

The Cherokee used *G. circaeazans* to treat coughs, hoarseness, asthma, and as an expectorant (Hamel and Chiltoskey 1975). The Ojibwa used *G. tinctorium* for respiratory problems, and the Micmac made a red dye from the roots for porcupine quills (Moerman 1998).

*Galium triflorum* was the most popular, or at least the most recorded, species among indigenous people. The Cherokee took an infusion for gallstones (Hamel and Chiltoskey 1975). The Iroquois made a poultice to stop backache in babies and used a poultice to relieve swollen testicles or ruptures (Moerman 1998). The Iroquois, Karok, and Quileute used it as a love medicine, which may not be different from the use as perfume among the Makah, Omaha, and Ponca, or in washing hair by the Nitinaht (Gilmore 1919, Moerman 1998).

### *Gaylussada*

(Named for Louis Joseph Gay-Lussac, 1778–1850, the French chemist who discovered the law of combining volumes of gases)

*Gaylussacia dumosa*. Drawn by  
P.N.Honychruch.

***Gaylussacia dumosa*** (dwarf)

*Buckelberre* (knot berry, German)

gopher-berry (New England)

[bushy, dwarf] huckleberry (see *Vaccinium* for derivation of huckleberry)

whortleberry (Williams [1837] 1962)

***Gaylussacia frondosa*** (leafy, from the bracteate) racemes)

blue-tangle; dangle-berry [dangleberry, tangleberry]

highberry

[blue, dwarf] huckleberry

*kuwaya* [*ku-wa-ya'*] (Cherokee)

***Gaylussacia mosieri*** (named for Charles A. Mosier, 1871–1936, the first superintendent of Royal Palm State Park, Florida's first state park, a friend and collaborator of J.K. Small)

woolly-berry

“You don’t know about me without you have read a book by the name of *The Adventures of Tom Sawyer*, but that ain’t no matter. That book was made by Mr. Mark Twain, and he told the truth, mainly. There was things which he stretched, but mainly he told the truth.” Those words came from one of the most famous literary characters of all times—Huckleberry Finn. I do not recall if Twain ever had Huckleberry and Tom eating huckleberries, but surely he did.

Hedrick (1919) obviously was not familiar with *Gaylussacia frondosa* when he wrote : “The fruit is large, bluish, rather acid and is used in puddings. The fruit is sweet and edible according to Gray.” According to Fernald and Kinsey (1943), the fruits will “make

one of the most luscious of desserts, being remarkably juicy and with a rich, spicy and sweet flavor.” Fernald et al. (1958) also spoke from experience when they wrote of *G. dumosa*, “On account of its habitat, in sphagnum bogs, the Dwarf Huckleberry is not generally known in the North; but its fruit is juicy and deliciously spicy. Southward, where it takes to dry sands, the fruit is readily accessible.” Yanovsky (1936) found records of both *G. dumosa* and *G. frondosa* being eaten by tribes in the eastern and southern states.

The Chickasaw are the only Muskogean people found using *Gaylussacia*. Roots from an undeter species were used to treat delirium (Taylor 1940). The Rappahannock used an infusion of dried or fresh roots to treat stomach problems (Moerman 1998). From the location of both tribes, the plants could have been either *G. dumosa* or *G. frondosa*. The more widespread northern *G. baccata* was used as food by the Cherokee, Iroquois, and Ojibwa. Both the Cherokee and Iroquois used that species to relieve dysentery and kidney problems, and to generally promote good health (Hamel and Chiltoskey 1975, Moerman 1998).

There is supposed to be a simple way to distinguish between huckleberries (*Gaylussacia*, berryli drupe with ten hard nutlets) and blueberries (*Vaccinium*, fruit a many-seeded berry). Most people can distinguish between them, but, once they taste the delicious fruits, their minds wander in ecstasy, and they intermix the names.

### *Gelsemium*

(A.L.de Jussieu, 1748–1803, Latinized the Italian *gelsomino*, jasmine, to create this genus in 1789)

***Gelsemium sempervirens*** (always green, or living forever)

*aatyammichi* (*aati*, Indian, *yammi-chi*, to get someone intoxicated, Alabama)

Carolina jasmine (jasmine or jessamine, is derived from Persian *yasmin*, *yasman*, plants of the “real” jasmine are *Jasminum* in the Oleaceae)

cow-itch (may cause contact dermatitis; the name also used for *Campsis*, which see)

***Gelsemium sempervirens***. From Britton and Brown 1897.

evening trumpet flower

*gelsemio* (jasmine, Mexico); gelsemium (in use as an English word by 1875)

[false, wild] jasmine [jessamine] (yellow jasmine [jessamine] (used by Williams [1837] 1962); yellow jasmine root

*jazmín amarillo* [*de Carolina, silvestre*] (yellow [Carolina, wild] jasmine, Mexico)

*madreselva* (mother of the forest, Mexico)

[wild] woodbine [wood vine] (originally a European term for *Convolvulus* and *Hedera*, dating to about A.D. 875, and alluding to climbing; now more often used for *Parthenocissus*)

William Bartram ([1791] 1958) wrote, “what seems remarkable, the yellow Jessamine, ...which is killed by a very slight frost in the open air in Pennsylvania, here on the summits of the Cherokee mountains [Oconee Station Mountain, South Carolina] associates with the Canadian vegetables, and appears roving with them in perfect blossom and gaiety.” He saw the plants again in several places, but never commented on their toxicity. Perhaps that was because he thought they belonged in the genus *Bignonia*. Catesby (1731–1932) had seen them earlier and called them *Gelseminum*, *sive Jasminum luteum odoratum Virginianum scandens, semper virens* (*Gelseminum* or yellow, fragrant, climbing jasmine from Virginia, always green). Apparently, Jussieu took his clue from Catesby in naming the genus. What British botanist Catesby was doing using an Italian plant name is not explained. Catesby wrote, “Altho’ Mr. Parkinson calls it *semper virens*, I have always found it lost its Leaves in Winter.” He referred to John Parkinson’s books on plants published in 1629 and 1640, so the climbers had been introduced into Europe long before.

*Gelsemium* has two species, with *G. sempervirens* ranging from the eastern United States to Guatemala. The other, *G. elegans*, grows in southeastern Asia to western Malesia (Mabberley 1997). The Old World species contains poisonous alkaloids like the American and has been used to commit murder and suicide. Formerly, the plants were included in the Loganiaceae, but now this genus and *Mostuea* are separated into the Gelsemiaceae (Cronquist 1981, Judd et al. 2002).

The Delaware in New England used *Gelsemium* roots as a blood purifier and in a healing salve (Moerman 1998). John Brickell praised the virtues of *Gelsemium* in 1737 and most likely learned of it from local tribes.

Apparently, the knowledge of using these vines for medicine was lost until it was again accidentally rediscovered in 1821. Francis Peyre Porcher (1825–1895) wrote in 1849 about a planter who was accidentally given a medicine from *Gelsemium* instead of the intended herb. Then, a proprietary nostrum called “Electric Febrifuge” began being sold, the primary ingredient of which was *Gelsemium* (Porcher 1863, Millspaugh 1892). This sparked interest in these plants that lasted for years. *Gelsemium* was listed in the U.S. Pharmacopoeia from 1863 to 1926 and in the National Formulary from 1926 to 1955. The plants are considered sedative, antispasmodic, and nervine, and are recommended as a treatment for asthma, cramps, fevers, hysteria, infantile paralysis, migraine, mydriasis, and tetanus (Hocking 1997).

However, extreme caution with these plants is advised. Ingestion of a single flower has caused death (Foster and Duke 1990). There are several alkaloids in the plants (Hocking 1997). The U.S. Dispensatory says those chemicals “in toxic doses [produce] almost complete paralysis” (Coffey 1993).

The most abundant toxins are gelsemine, gelsevirine, gelseminine, gelsemicine, gelsemoidine, gelsenicine, and koumidine (Lampe and McCann 1985, Nellis 1997). These chemicals act much like strychnine in blocking muscle activity and can mimic symptoms of tetanus. Even honey made from the nectar is suspected of causing human deaths (Nellis 1997). On the positive side, gelsemine is analgesic, slows the heartbeat, and reduces blood pressure. The *British Pharmaceutical Codex* suggests use of the powdered roots to treat trigeminal neuralgia and migraine headaches. However, dosage is critical.

### *Genipa*

(From Tupi *ñandi'pab*, dark color on the chest, now rendered *jenipapo* in Brazilian Portuguese; formerly *Casasia*, named for Luis de las Casas, Captain General of Cuba)

***Genipa clusiifolia*.** a. Cluster of staminate flowers, b. Flower, side view, c. Flower, from above, d. Staminate flower, longitudinally dissected, with insert of stamen, e. Pistillate flower, longitudinally dissected, f. Floral diagram of

staminate flower, g. Floral diagram of pistillate flower, h. Branch with fruits, i. Fruit in transverse section, with seeds as insert . *Drawn by Priscilia Fawcett*. Correll and Correll 1982.

***Genipa clusiifolia*** (leaves resembling those of *Clusia*) (= *Casasia clusiifolia*)

*jagua de costa* (coastal *jagua*, Taino for Rubiaceae); *jagüilla* (little *jagua*, Cuba)

seven-year apple (Florida, Bahamas)

The best-known species in this genus is the one Linnaeus described in *Systema Naturae* in 1759, *Genipa americana*. However, Jacquin named this Caribbean species in 1796, and it was moved to *Genipa* in 1861. There are only seven species in the genus, all of them tropical American (Mabberley 1997).

Roig (1945) said *G. clusiifolia* has the same properties as *G. americana*. The most famous use of *jenipapo* is as a body dye among the indigenous people of South America. The iridiod genipin turns black when it combines with proteins in the skin, and it is widely used as body coloring. When applied to garments, it produces a blue dye. Fruit pulp also is used to treat dysentery and syphilis, but the seeds are emetic (Mors et al. 2000). Contents of the ripe fruit of *G. clusiifolia* are edible (Morton 1968b), but not good. I consider them disgusting.

### ***Gentiana***

(Pliny, A.D. 23–79, and Dioscorides, fl. A.D. 40–80, said that Gentius, last king of Illyria, ca. 180–168 B.C., discovered the medicinal virtue of the plants and they named the genus for him)

***Gentiana saponaria***. From Britton and Brown 1897.

*Bitterwurz* (bitter herb, German, used by Fuchs 1542)

*creamh* (nibble, Gaelic)

*currac-an easbuig* (*currac*, cap, an, of, *easbuig*, Bishop, Gaelic)

felworts (“fell” in this sense is from *Latin fell*, gall or bitter; wort, plant, England)

*genciana* (Spanish, Portuguese); gentian (first recorded in English about A.D. 1000); *Enzian* (German, used by Fuchs 1542); *gentiane* (French); *genziana* (Italian)

*lús a chrùbain* (the crouching plant, Gaelic)

*søte* (sweet, Norwegian)

*ton-ga-shin-ga* (it gives strength to a child; *on-k'i*, to give, *zhin-ga'* child, Osage)

***Gentiana catesbaei*** (named for its discoverer, Mark Catesby, 1679–1749)  
bitter-root [bitterroot]

blue-bells [bluebells] (a name now used for *Campanula*, Campanulaceae, *Mertensia*, Boraginaceae, or *Lupinus*, Fabaceae)

Catesby's snakeroot

[American, blue, southern] gentian

*nipi lapushkichi* (*nipi*, meat, *lapushkichi*, little soft, Choctaw)

Sampson's snake-root (South Carolina, Porcher 1863; common name also applied to *Gentiana villosa* and *Psoralea psoraloides*)

***Gentiana saponaria*** (from resemblance of foliage to that of *Saponaria*, Caryophyllaceae, usually called “soapwort”)

harvest-bells [harvestbells]

*makan chahiwi-cho* (*makan*, medicine, *chahiwi*, blossom, *cho*, blue, Winnebago)

*pezhuta-zi* (*pezhuta*, medicine, *zi*, yellow, a reference to the color of the roots, Dakota)

soapwort gentian

***Gentiana villosa*** (long-haired)

blue-bells [bluebells] (a name usually given to *Campanula*, Campanulaceae, *Mertensia*, Boraginaceae, or *Lupinus*, Fabaceae)

Calathian-violet (originally used by John Gerarde in 1597 for another species; a calthus, from Greek *kalathos*, is a vase-shaped basket, an allusion to the corollas)

[blue, marsh, rough, straw-colored, striped] gentian

harvest-bells

Sampson's snakeroot

The writings of Pliny and Dioscorides affirm that people were using a Mediterranean gentian long before the New World was discovered. Indeed, the use of gentians as medicine is recorded on a papyrus found in an Egyptian tomb at Thebes and dated to ca. 1180 B.C. (Dobelis 1986).

The most famous of the gentians was what Linnaeus called *Gentiana lutea* in 1753. His was one of many publications mentioning the herbs as medicine, and it had been discussed by Fuchs (1542), Joachim Camerarius (1534–1598) in 1588, John Gerarde in 1597, Paul de Reneaulme (ca. 1560–1624) in 1611, Gaspar Bauhin in 1623, and others.

*Gentiana lutea* is a mountain plant of southern Europe, growing in much of the Mediterranean. Linnaeus ([1753] 1957) wrote, “*Habitat in alpibus Norvegicis, Helveticis, Apenninis, Pyrenaeis, Tridentinis*” (Grows in the mountains of Norway, Switzerland, the Apennines [of Italy], the Pyrenees [of France and Spain], and the Tridentine [Alps of northern Italy]). The underground stem of *G. lutea* is used to make gentian bitters and brandy (to aid digestion and stimulate the appetite). It was a nerve tonic used by the ancient Greeks as a poison antidote (Bremness 1994). The plant is also an ingredient in vermouth and Angostura bitters.

When Europeans arrived in the New World, they found a variety of new gentians. Linnaeus ([1753] 1957) named both *G. saponaria* and *G. villosa*, the first discussed before him by Robert Morrison’s list of cultivated plants in London, Mark Catesby, and Jan Gronovius. *Gentiana villosa* was known to Linnaeus only from the Clayton collection from Virginia and Gronovius’s comments in his *Flora Virginica* published between 1739 and 1743. *Gentiana catesbaei* was described by the Charleston planter, Thomas Walter (1740–1789), in his *Flora Caroliniana*, published in 1788. Kartesz (1994) listed 34 species in North America and Greenland.

Considering the popularity of gentians in Europe, there are surprisingly few records among indigenous people in North America. With the sparsity of records of *Gentiana* use among indigenous people until well into the 1800s, we must wonder who taught whom about their use.

Two tribes are recorded as using *G. catesbaei*. The Catawba of South Carolina used the herb to stop pains in the stomach by drinking a hot or cold infusion, or the roots were chewed. The Catawba also applied it to cure backache. The Choctaw treated snakebite with it (Swanton 1931). Smoky Mountain settlers used it against colic (Krochmal 1968, Vogel 1970).

Although they did not mention American tribes, two early books were surely influenced by local uses. Jacob Bigelow (1786–1879), who published *American Medical Botany* between 1817 and 1821, discussed use of *G. catesbaei*. Another early record was by John Woods, an Englishman who founded a colony of expatriates at Albion, Illinois, in 1821. He wrote that they adopted as medicine “snake-root, gentian, gensing, Columbia-root, sumach, and sassafras tree” (Kindscher 1992). Perhaps part of the lack of documentation is that people were not that careful to distinguish between *Gentiana* species, considering them all useful as “bitters.” Although neither Bigelow nor Woods specifically mentioned indigenous uses, it has been assumed that they learned from them. Use was clearly widespread because *G. catesbaei* was official in the U.S. Pharmacopoeia between 1820 and 1882, as a bitter tonic and substitute for *G. lutea* (Vogel 1970). The U.S. Dispensary in 1955 said the species was “reputed to be but little inferior to the official species [*G. lutea*], the most popular of all bitters in the treatment of atonic dyspepsia, anorexia, and similar complaints” (Coffey 1993).

Porcher (1863) praised “Sampson’s snake-root” highly as bitters. He further indicated, “*Gentiana purpurea*, *rubra*, and *lutea* are used in England as substitutes for hops. No doubt our species would serve the same purpose; at any rate, they will give a bitter tonic

property when used in the manufacture of ale, beer, etc.” Millspaugh (1892) simply said Catesby’s snakeroot was a substitute for *G. lutea*. Hocking (1997) wrote that *G. catesbaei* was used like *G. lutea*, as a bitter, particularly by German manufacturers as *Enzianschnapps*, and that it was a source of “official Gentian.” Newsom (1989) provided an updated view of the species in medicine.

The Dakota and Winnebago used a simple or compound decoction of *G. saponaria* roots as a tonic (Gilmore 1919). Although no records of indigenous tribes using *G. villosa* have been found, it is famous in the Appalachians. Krochmal and Krochmal (1973) wrote: “Root tea is drunk as tonic, and a piece of the rhizome sometimes is carried or worn in the belief that it will increase one’s physical powers. The rhizome has been used to treat indigestion, gout, and rheumatism, and to induce vomiting. It has also been used as a tonic, as a digestive aid, for nervous distress, and gout.”

Wunderlin (1998) also lists *G. pennelliana* for Florida. It would be surprising if people there had not also used it, but no records have been found.

Duke et al. (2002) list many attributes for *G. lutea* that are considered applicable to *Gentiana* generally (Moore 1979). The bitter compounds are typically glycosides (Simonetti 1990), and roots of gentians contain gentisin, gentianin, gentiamarin, and aromatics. Gentiopicroin is the compound contributing to the use as a bitter tonic and, when the roots are chewed, aids in breaking the alcohol habit (Hocking 1997). Regarding malaria, Porcher (1863) wrote: “It is believed by many that the use of bitters in spring and autumn will counteract the action of malaria. They certainly prevent debility, and increase the digestive and nutritive powers, and thus indirectly act as prophylactics, even when they possess no positive virtue as antiperiodic agents.” That seems to be one of the few cases where people in the 19th century were conservative about treating that disease, because Moore (1979) noted that gentiopicroin is still used in Pharmaceuticals to treat malaria. Gentisic acid is used now principally for rheumatic inflammations (Moore 1979).

Among the most recent chemical analyses of other *Gentiana* are several that report new types of chemicals and reconfirmation of effectiveness. Kakuda et al. (2001, 2002) found several new triterpenoids and secoiridoid glycosides along with those already known. Rojas et al. (1999, 2000) found in *G. spathacea* muscle relaxing (spasmolytic) properties that compared with those of *Datura*. Research on plants used in Tuscany, Italy by Uncini et al. (2000) found extracts from *G. kokiana* were antihypertensive and supported the herb’s local use to treat hypertension. There may also be free radical-scavenging action in *G. decumbens*, an herb long used as medicine in Mongolia (Maygmar and Aniya 2000).

Moore (1979) considered a gentian: “The best possible remedy for a person with chronic indigestion and dyspepsia in the evening.” He was not alone in that opinion. In 1983, at age 84, E.B.White, the author of *Charlotte’s Web*, wrote in praise of gentians (Coffey 1993): “I can still buy Moxie in a tiny supermarket six miles away. Moxie contains gentian root, which is the path to the good life.”

*Geranium*

(An old Greek name, *geranion* is from *geranos*, a crane; the long beak-bearing fruit was thought to resemble the bill of that bird)

***Geranium carolinianum*.** a. Habit of plant, b. Flower, c. Seed pod enclosed by calyx, d. Seed. From Buchholtz 1968.

*anda'nk'alagiski* (it removes things from the gums, for *G. maculatum*, Cherokee)

*be'cigodji'bigûk* (one foot, for *G. maculatum*, Ojibwa)

*bec a gru* (crane's bill, in use by 1549, French); cranes bill [cranesbill] (in use by 1548 when Turner spelled it "Cranes byl")

*erba roberta* (Robert's herb, Italian); *erva roberta* (Portuguese); herb Robert [herb Roberte] (for *G. robertianum*, named for St. Robert; used in Henry Lyte's 1578 translation of Dodoens's *Cruydeboek*); *herbe à Robert* (in use by 1550, French); *hierba de San Roberto* (Spanish); *robrechtscruyt* (in use by 1549, Dutch); *Ruprechtskraut* (in use by 1542, German)

*l'esquinancie* (from medical Latin *cynanche*, Greek *kynankhe*, dog-collar, because of the strangling sensation of the ailment, which is called "quinsey" in English; *G. robertianum* was used to treat the problem, Quebec)

*geranio* (Spanish)

*lús an ròis* (plant of the rose, a disease; the same as quincey?; for *G. robertianum*, Gaelic)  
*ruideal* (probably “red-haired,” for *G. robertianum*, Gaelic)  
*stankstorkenebb* (stinking stork’s bill, Norwegian)

***Geranium carolinianum*** (of Carolina)  
 Carolina geranium  
 crane’s bill  
*pata de león* (lion’s foot, Mexico)

While the similarity is not always easy to see without knowing cranes (*Grus grus*) as did the Europeans, the Greeks compared fruits of these bright-flowering herbs with those birds. Early botanists were so captivated with the comparison that they continued the analogy with *Erodium* (from *erodios*, heron) and *Pelargonium* (from *pelargos*, stork) for related genera in the Geraniaceae.

Although there are more species of *Geranium* in Europe, Fuchs (1542) listed five (*G. dissectum*, *G. pratense*, *G. rotundifolium*, *G. robertianum*, *G. sanguineum*). The most famous of these is herb Robert. Culpeper (1653) and other herbalists recommended this plant for a variety of ailments, but mostly to stop bleeding and help wounds heal.

When they arrived in the New World, Europeans found that indigenous people were also using *Geranium* as medicine. Moerman (1998) listed eight species that are known to have been used. In the east, the most famous of these is *G. maculatum*. That species was used by the Cherokee, Choctaw, Iroquois, Menomini, Meskwaki, and Ojibwa. The major uses of this species were to stop bleeding, diarrhea, and dysentery, and to help cure sores. Because it has 10 to 20% tannin in the roots, it is highly astringent and effective for those purposes (Foster and Duke 1990).

*Geranium carolinianum* is a miniature version of *G. maculatum*. This diminutive herb grows from Massachusetts, Connecticut, and New York west to Michigan and southern British Columbia, and in the south from Florida to California (Fernald 1950, Steyermark 1963, Correll and Johnston 1970, Barkley 1986, Hickman 1993, Diggs et al. 1999). The herbs also continue south to San Luis Potosí in Mexico.

Hartwell (1967–1971) recorded that *G. carolinianum* had been used against cancer. In Japan, where the herbs are exotic, they are considered antidiarrheic and stomachic (Duke 2003). Hocking (1997) unfortunately neither lists his source nor tells who he found using the herbs. However, he records that the plant has been used to treat fever, as a diuretic, as a purge for children (not adults), and in a decoction for rash in children. Leaves and roots are crushed and boiled to make a syrup to treat dysentery.

### *Gleditsia*

(Linnaeus named this tree for his contemporary German Johann Gottlieb Gleditsch, 1714–1786, director of the Berlin Botanic Garden)

***Gleditsia triacanthos*.** From Sargent  
1905.

***Gleditsia triacanthos*** (three-thorned)

acacia (used by Plukenet in 1700); *acacia de tres espinas* (three-spined acacia, Spanish); *acacia negra* (black acacia, Argentina); *acacia tres puas* (three-spined acacia, Spain); three-thorned acacia

*algarrobo de miel* (honey mesquite, a name also given to *Prosopis*)

black locust (confusion with *Robinia*)

*cawwimeysa* (Shawnee, fide Edgar 1891); *pitelawe minschi* (*minschi*, plant, Delaware)

*Christusdoorn* [*christus-dorn*, *korstorne*] (Christ's thorn, Dutch); *Christusdorn* (Christ's thorn, German); *valsa Christusdoorn* (false Christthorn, Dutch)

Confederate pintree (USA)

*Dornbaum* (thorn tree, German); *Schotendorn* (pod thorn, Germany)

*espinheiro da Virginia* (Virginia spine tree, Portuguese)

*févier a trois épines* (three-spined *Gleditsia*, France)

honey [shuck, honeyshuck, shucks honey locust] ("honey" is a Teutonic word derived from Old English and Old Frisian *hunig*, dating from ca. A.D. 825; said to have been originally applied to the product of honeybee, *Apis mellifera*, and surely first used for other sweet products of nature as those animals were brought into northern climes from the Mediterranean)

[common] honey locust (in use by 1812)

*kati* (Choctaw); *kati'* (Chickasaw); *kvtókwv* (Muskogee); *tato* (Alabama); *tató* (Koasati)

*kulse'tsi* [*kulsétsi*] (Cherokee; *Kulsetsiyi*, abbreviated *Kulsetsi*, "Honey-locust place," was the name of several former settlements in the old Cherokee country. One was on Keowee River, near the present Fall Creek, in Oconee County, South Carolina; another was on Sugartown or Cullasagee or *Kulse'si* Creek, near the present Franklin, in Macon County, North Carolina; a third was on Sugartown Creek, near the present Morgantown, in Fannin County, Georgia. The local name was rendered Sugartown by the traders.)

locust (from Latin *locusta*, through Old French *locuste*; originally applied to the insects in the Acridiidae; in English about A.D. 1200; the

same Latin word was also applied to legume fruits, first the carob, *Ceratonia siliqua*, in the Levant, and then to other species)

*nit* (Atakapa)

*piquant amourette* (prickly love affair, French)

*spino di Giuda* (Judas's spine, Italian)

squeak-bean; sweet-bean

sweet locust (in use by Porcher 1863)

thorn(y) [locust, tree, acacia] (USA)

*ya pate* (flat [pod] tree, Catawba) *zinhawarātschi* (Onondaga)

*Gleditsia* is a legume genus of 12 species, with 2 or 3 in eastern North America, 1 in South America, 1 in the Caspian, and the rest from India to Japan and New Guinea (Mabberley 1997). The common names are often used interchangeably, but the “preferred” nomenclature is to call this genus “honey locust” to distinguish it from “black locust” (*Robinia*).

Trees were imported to Europe by the latter 1600s. Leonard Plukenet included them in his *Almagesti botanici mantissa* of 1700. He thought they were like those known from the Mediterranean and called them *Acacia americana*, *abruae folio*, *triacanthos* (American acacia with delicate leaves, three-spined). Mark Catesby reported them next and used Plukenet's name. However, the latest interpretations of his plate (#43) have identified his drawing as *G. aquatica* (Howard and Staples 1983, Wilbur 1990). That species was not formally named until Humphrey Marshall (1722–1801) described it in 1785.

By 1753, Linnaeus had studied living *G. triacanthos* in both the *Hortus Cliffortianus* published in 1738 and the *Hortus Uppsaliensis* of 1748. Between those books he decided to name it after Johann Gleditsch and coined *Gleditsia* in 1748.

The sapwood of honey locust is yellowish, while the heartwood is light red to reddish brown; it has no characteristic odor or taste. The wood is heavy, hard, tough, strong, and has a high luster (Sargent 1905, Harrar and Harrar 1946, Alden 1994a). Posts buried in the ground practically never rot (Coon 1974). The wood has been compared with black locust (*Robinia pseudoacacid*) in terms of strength, second only to that legume. The Cherokee used the wood, at least in later years for fence posts (Hamel and Chiltoskey 1975). Because they used posts in some of their buildings earlier, they were likely used then also. The Cherokee also made bows from the resilient wood (Steyermark 1963).

Porcher (1863) wrote: “The pores of the wood are very open. When perfectly seasoned, the wood is extremely hard. It is far inferior to the black walnut or wild cherry for cabinet-making. Hedges of it are rendered impenetrable by its long thorns.” The wood has also been used to make posts, cross ties, wheels, and other items (Sargent 1905, Harrar and Harrar 1946). Hocking (1997) found that the bark had been used in tanning leather; Duke (2003) recorded ample tannin present.

Steyermark (1963) recorded uses that are probably typical of those elsewhere in its range. In Missouri, he found country people tying the large thorns to poles for use as “gigs” for bullfrogs. Other people used the thorns as large needles or pins for closing woolen sacks, and for carding wool. These uses are reflected in the name “Confederate pintree.”

William Bartram gave the first record of Creek and Cherokee uses of honey locust in response to Benjamin Barton's questions in 1789. He wrote, “They have in use a vast

variety of native or wild vegetables, both fruits and roots” (Bartram in Swanton 1946). Primary among those listed were persimmon, mulberries, and honey locust. Because of the comments by Mooney that the Cherokee “extracted their only saccharine from the pod of the honey locust, using the powdered pods to sweeten parched corn and to make a sweet drink” (Swanton 1946), there is corroboration for Bartram’s comments. If either tribe used the roots of honey locust as Bartram implied, no other record has been found. However, the Catawba did eat the pods and mix them with bread and drink (Speck 1934).

Hocking (1997) wrote that the pods were used for sweetener, and mixed with sweet acorns to make edible cakes. He noted that legumes were used to make beer by slaves, but gave no source. Perhaps he was referring to Porcher (1863), who recorded, “Beer is sometimes made by fermenting the sweet pods while fresh.” Fernald et al. (1958) found the pulp, “a well known pleasant nibble.” Steyermark (1963) wrote from personal experience that the “thin jellylike pulp surrounding the seeds is sweet and provides a somewhat pleasant diversion to taste when one is tramping outdoors.”

The people of the eastern United States also employed these trees for medicine. Among the tribes who use them are the Cherokee, Creek, Delaware, Meskwaki, and Rappahannock (Moerman 1998). The Cherokee used fruits to sweeten worm medicine and to treat dyspepsia, measles, and whooping cough (Hamel and Chiltoskey 1975). The Creeks made medicine to treat smallpox, and for children’s “complaints” (diarrhea?) (Swanton 1928, Taylor 1940). The Delaware mixed the bark with that of prickly ash (*Zanthoxylum americanum*), wild cherry (*Prunus virginiana*), and sassafras (*Sassafras albidum*) to make a tonic to “purify the blood” and to relieve coughs. The Meskwaki made an infusion of the twigs to treat colds. They used the bark to treat fevers, measles, smallpox, and to help an ill person regain strength. The Rappahannock made an infusion of bark and roots to help recover from colds and coughs.

The species is oddly absent from both Millspaugh (1892) and Vogel (1970). Foster and Duke (1990) found that the pods were formerly made into tea to treat indigestion, measles, and catarrh of the lungs. An inner bark tea with sycamore bark (see *Platanus*) was once used to relieve hoarseness and sore throat. Juice of the legumes is antiseptic, and compounds from the leaves retard certain types of cancer.

Several chemicals have been isolated from *Gleditsia*. Duke (2003) found that the fruits contain (+)catechin, (–)epicatechin-3-glucoside, carbohydrates, fats, fiber, glucose, leucocyanidin, and protein. Seeds are known to have 7,3',4',5'-tetrahydroxyisoflavanol, acetic acid, calcium, carbohydrates, dihydroxystearic acid, fat, fiber, galactose, mannogalactan, mannose, phlobaphene, phosphorus, protein, sativic acid, tetrahydroxystearic acid, and tocopherols. There are a number of other compounds known in other plant parts.

Foster and Duke (1990) also warn that “All plant parts...contain potentially toxic compounds.” However, Duke et al. (2002) record that the plants have analgesic, antidote, antitussive, cytotoxic, depurative, mydriatic, narcotic, oxytotic, poisonous, and toxic qualities, and are used as a vasodilator. They give the herbal remedy from *Gleditsia* two plus marks (as safe as coffee).

***Gnaphalium***

(Linnaeus based this on Greek *glaphallion*, *knaphallon*, soft down, woolly, referring to the pubescence of the plants)

***Gnaphalium obtusifolium*.** a. Upper part of a flowering plant, b. Seed.  
From Buchholtz 1968.

*cat-luibh* [*luibh-a-chait*] (cat-herb, Gaelic)  
 cud-weed (English)  
*gnaphale* (French)  
*impia* (Italian)  
*Ruhrkraut* (dysentery herb, German)

***Gnaphalium obtusifolium*** (uneven leaves) (= *Pseudo-gnaphalium obtusifolium*)  
*ahalla'ta'* (Chickasaw)  
*ahá Ivbykca* [*ahá labakca*, *aha-lopv'kcv*, *ahalobaktsi*, *halobaktei*] (*vhy*, root, *Ipyvke*, wild, Creek, Muskogee)  
*ahisi laksa* (*ahisi*, tobacco, *laksa*, bitter, Alabama)  
*bashûchak* (Choctaw)  
 cat-foot (USA)

chafe-weed (USA)  
cudweed (chewed as cud, like tobacco, USA); fragrant cudweed  
[everlasting] (Texas)  
[life, sweet] everlasting (for long-lasting dried flowers, USA); life  
alasses (Gullah, South Carolina)  
Indian tobacco (USA); rabbit tobacco (Florida)  
*iskafotó stokhátká* (*iskafotó*, mountain mint, *stokhátká*, gray, Koasati)  
*kasd'uta* (simulating ashes, Cherokee)  
*napopokpoke* (*nam pakanli*, a flower, Choctaw)  
old field balsam (USA)

*Gnaphalium purpureum* (purple) (= *Gamochaeta pur pur ea*)  
*patte de chat* (cat foot, Houma, Louisiana)

Linnaeus created the genus *Gnaphalium* in 1753, and included 36 species. Both *G. obtusifolium* and *G. purpureum* were on the list. He had seen neither of those alive, but knew them from herbarium specimens and literature, beginning with Robert Morrison's (1620–1683) account of both in 1680. However, Linnaeus did know living plants of the single European *G. dioicum*, and had discussed it in his *Materia Medica* of 1749. He had seen others cultivated at both the *Hortus Cliffortianus* and *Hortus Upsaliensis*. Mabberley (1997) included about 50 species in *Gnaphalium*, and he called the genus “cosmopolitan.”

Virtually all who live near *Gnaphalium* have used it. The most pervasive common name in English is “rabbit tobacco,” which indirectly records the indigenous practice of mixing the leaves with tobacco (*Nicotiana* spp.) for smoking. That combination was typically to avert sickness or witchcraft (Swanton 1928a, Taylor 1940, Howard 1984, King 1984). An old use still practiced is in treating colds and lung pains (Bushnell 1909, Swanton 1928a, Bennett 1997). The plants are either used alone or mixed with others to treat mumps, upset stomach, nervousness, and insomnia (Howard 1984). These two species were used by at least the Alabama, Cherokee, Chickasaw, Choctaw, Creek, Koasati, Menomini, Meskwaki, Montagnais, Potawatomi, and Rappahannock. Murphee (1965) found people in the Panhandle putting dried leaves in pillows to relieve asthma. Other people, and probably these too, used other species. Several other species are still used today (e.g., Laferrière 1994, Yetman and Van Devender 2001).

### *Goodyera*

(Named for British botanist John Goodyer, 1592–1664, of Mapledurham, Hampshire, who is probably most famous for his translation of Dioscorides's *Materia Medica*, which was not discovered and published until 1934, some 250 years after it was written)

creeping lady's tresses (comparison with *Spirant ties*, which see)  
*goodyère* (this is a recent name; the genus was not named until 1810, French)  
*kêdîgibagûk* (spotted leaf, Potawatomi)

*knerot* (knee root, Norwegian)  
*mogairlean ealaidheach* (creeping orchid, Gaelic)  
*Netzblad* (net-leaf, German)

***Goodyera pubescens* (hairy)**

adder's-tongue [cactus, violet] (Maine)  
 canker-root [cancer-weed] ("canker" is a variant of "cancer," but also perhaps a reference to thrush or *Candida* infection)  
 lattice-leaf  
 net-wort [networt]  
 [spotted, net-leaf]-plantain  
 ratsbane (North Carolina)  
 rattlesnake-[leaf, orchid, root, tongue, violet], (New Jersey, New York)  
 [downy] rattlesnake plantain (in use since 1846; from the indigenous people chewing the leaves and applying them to rattlesnake bites, cf. Core 1967; but a different explanation was offered by Frère Marie-Victorin in his *Flore laurentienne* of 1935; he wrote, "these plants superficially resemble the Plantains; on the other hand, the leaf patterns, which resembles a snake skin, suggested the idea [doctrine of signatures] to the first American settlers to use the Goodyers as antidotes to snake venom")  
 scrofula weed (scrofula is a tubercular disease)

Many early botanists in Europe commented on their species, *Goodyera repens*. They called these ground orchids by various names. Joachim Camerarius, in his *Hortus medicus* of 1588, and Christian Mentzel, in his *Pinax* of 1682, thought the herbs should be called *Orchis* (testicle). Gaspar Bauhin called it *Pseudoorchis* (false-testicle) in his *Pinax* of 1623. Peter Johannes Loesel, in the *Flora Prussia* of 1703, put it in *Pyrola* (little pear, from the leaf shape, Ericaceae). Linnaeus was consistent in naming it *Satyrium* (the Greek *satyr*) from his *Flora Lapponica* of 1737 to *Species Plantarum* ([1753] 1957). Thomas F. Dalibard, in his *Flora Parisiensis*, published in 1749, agreed. *Flora Sibirica*, published between 1747 and 1749 and authored by Johann G. Gmelin (1748–1804), called it *Epipactis* (*epi*, upon, *paktos*, hellbore or *Helleborus*). Finally, in 1810, British botanist Robert Brown (1773–1858) created the genus *Goodyera* for these circumpolar orchids.

At first, it seems odd that there are only French names for these orchids in southern Europe. However, a comparison of its range reveals that they are absent from most of southern Europe, with the exception of the Pyrenees Mountains in France (Polunin 1969).

The Cherokee used *G. pubescens* as a blood tonic, for burns and colds, as an anemetic, to improve the appetite, and to treat sore eyes, kidney problems, and toothache (Hamel and Chiltoskey 1975). The Delaware and Mohegan used it for pleurisy, rheumatism, sores, and thrush (*Candida*), and to treat women after childbirth (Moerman 1998).

Frederick Pursh said in 1814 that the orchids had a reputation as an infallible cure for hydrophobia. Near the same time in New England, they were regarded as a remedy for skin diseases (Coffey 1993). Thoreau did not care much about the orchids' reputation as a medicine. He wrote in 1851: "[I]t may not be easy to convince a quibbler and proser of its [common name, rattlesnake-plantain] fitness. We want some name to express the mystic

wildness of its rich leaves. Such work as men imitate in their embroidery, unaccountably agreeable to the eye, as if it answered its end only when it met the eye of mañ; a reticulated leaf, visible only on one side; little things which make one pause in the wood, take captive the eye” (Coffey 1993).

Porcher (1863) does not mention these plants, and Millsbaugh (1892) simply says, “a reputed American remedy for scrofula.” Vogel (1970) makes no mention of these orchids, nor do Duke et al. (2002). Perhaps the rarity of these orchids in Europe and the Americas led to them being overlooked by many. They were not mentioned by Europeans Fuchs (1542) or Culpeper (1653) either.

Beginning in 1918, Meyer and Meyer (1986) remembered: “The fresh leaves are steeped in milk and applied as a poultice to bruises, bites of insects, skin irritations. The leaves also may be used whole if preferred.” Foster and Duke (1990) added: “Physicians once used fresh leaves steeped in milk as poultice for tuberculosis swelling of lymph nodes (scrofula). Fresh leaves were applied every 3 hours, while the patient drank a tea of the leaves at the same time.” Then they quietly explain most of the absence from the herbal literature with “Of historical interest only. Too scarce to harvest.”

### *Gordonia*

(Named by John Ellis for the English nurseryman James Gordon, 1708–1781, gardener and correspondent of Linnaeus)

***Gordonia lasianthus*.** From Sargent 1905.

***Gordonia lasianthus*** (*last*, shaggy, hairy, *anthos*, flower)  
 black laurel *ittomico* (*eto*, tree, *mekko*, chief, Creek; given by Simmons [1822] 1973; the name was used earlier by William Bartram for *Persea borbonia*, which see)  
 loblolly bay (wetland bay; see Austin 1991 for etymology of “loblolly”)  
 red bay (Bartram [1791] 1958; a name usually given to *Persea*, which see)  
*to:li* (Mikasuki)

Before I noticed that Linnaeus called loblolly bay *Hypericum lasianthus* in 1753, it never occurred to me that the two families were that similar. Both have many stamens, three to

five carpels, and both may be woody. However, *Gordonia* lacks the pellucid dots that are so characteristic of *Hypericum*. Regardless, in 1771, John Ellis, an Irish-born merchant in London, (1710[1711?]-1776) put Linnaeus's species in *Gordonia*, a genus he created for that species. Today there are 70 species in *Gordonia*, with most native to southeastern Asia (Mabberley 1997). *Gordonia lasianthus* is the only species in North America (Kartesz 1994).

The Seminoles formerly distinguished between what we call *Persea borbonia* and *Gordonia lasianthus*, although now either is likely to be called *to:li* (Mikasuki) or *to: la* (Creek) (see *Per sea*: Red bay). Bartram ([1791] 1958) called *G. lasianthus* both red bay and loblolly bay. Perhaps the two have been used similarly or even interchangeably. At least the Koasati used *Gordonia* medicinally (Taylor 1940).

### ***Gossypium*: Cotton**

(From the Latin *gossipion*, used for the cotton plant by Pliny, A.D. 23–79)

***Gossypium hirsutum*.** a. Branch with flower, b. Flower, from above, c. Base of flower, longitudinally dissected, d. Detail of gland at base of calyx lobe. e. Calyx, from within, f. Calyx with young fruit, g. Floral diagram, h. Undehiscent fruit, i. Dehiscent fruit with cottony seeds. *Drawn by Priscilla Fawcett. From Correll and Correll 1982.*

Europeans were so accustomed to cotton that, when they found it in the Caribbean, they were none too impressed (Sauer 1969). Everywhere the earliest Spanish went in the Caribbean, they found two kinds of cotton (*Gossypium barbadense* and *G. hirsutum*), both different from those they knew at home (*G. herbaceum*).

Cotton was a comparatively new crop in Europe, having arrived in the Near and Middle East during Hellenistic and Roman times (Zohary and Hopf 1993). Indeed, the word "cotton" in English and the Romance languages was derived from Arabic (*qutun*, *qatn*) because traders brought the word and plant to Europe via Spain. That origin, instead of from *gossypion*, is one of the few instances in the Romance languages where the Latin word was superseded by another. Italian, usually closest to the Latin base word, uses *cotone*. Similarly, in French it is *coton*, and the Portuguese say *cotão*. The Spanish, misunderstanding the articles of Arabic, call it *algodón*, derived from *al-qutun* [*al-qoton*] (the cotton). The English began using words "*cotoun*" and "*coton*" about A.D. 1300, and even in Gaelic it is *cotan*. Germans say *Baumwolle* (tree wool), and the Creole Dutch say *katuna* or *kaloen* (Dutch Antilles). However, the people in the Dutch Antilles also call it *watten-struik* (wadding bush).

The Spanish were astonished at the quality of cloth produced from Cuba and Hispaniola to Mexico, and later from what became Arizona in the south-western United States. Each of the peoples they met seemed to outdo the others in the quality of the cotton fabrics they created. One of the reasons that indigenous Americans produced such outstanding cloth, beyond their skill as weavers, was the lint or fibers from the cotton. American plants produced longer and higher-quality lint than Old World species. Now, in one form or another, American species constitute ~95% of the world production (Simpson and Ogorzaly 1995).

Florida's cotton is *G. hirsutum*, and it is usually just called wild cotton (Florida, Puerto Rico) or native cotton (Puerto Rico). The remarkable thing about that species in Florida is that it extends from there through Central and part of South America and up Mexico to the Pima of Sonora and modern Arizona. It is not an accident that modern production is dominated by "Pima cotton," although that name applies to three different entities (Rea 1997). What is grown now (*G. barbadense*) is not the same that was originally grown by the Pima (*G. hirsutum*), but the area still produces quality cotton.

Although recent genetic studies show that they are not viable taxa (Fryxell 1988, Wendel and Albert 1992, Wendel et al. 1992), it is still convenient to recognize three morphological groups within *G. hirsutum*. The Caribbean tree cotton (var. *marie-galante*) was the West Indian type, growing through the Greater Antilles, from Panama to Trinidad and in South America to northern Brazil. Variety *lalfolium* was endemic to southern Mexico and Guatemala. This variant is known from about 3500 B.C. in Mexican archaeological sites (Smith 1968). Variety *punclalum* grew from the Bahamas and Florida around the coasts of the Gulf of Mexico to Yucatan. The modern forms called "Upland" cotton were derived from greenfuzzed seed types and named after their introduction into the southeastern United States in the 1700s to distinguish them from the black-seeded Sea Island cotton (*G. barbadense*). It was only in the 1800s that the gray- and white-fuzzed seeds were introduced to become the modern "Upland" cottons (Purseglove 1968).

Mostly, *G. hirsutum* is called tree cotton, as in *algodón arbórea* (Puerto Rico), *algodonero* (cotton tree), cotton bush (Virgin Islands), cotton tree (Belize), *cotonnier*

(cotton tree, Guadeloupe, Martinique), *palo de algodón* (tree cotton, Morton), and tree cotton (Puerto Rico). There is such variation with *G. hirsutum* that people named the types in different ways. Some distinguish the wild from the cultivated with *algodón criollo* (creole cotton, Cuba), *algodón del país* (country cotton, Puerto Rico), *algodón de altura* (upland cotton, Venezuela), *algodón silvestre* (wild cotton, Puerto Rico), *coton pays* (wild [country] cotton, Guadeloupe, Martinique), *coton sauvage* (wild cotton, Haiti), and wild cotton (Belize). Others separate them by the color of the lint. While people refer to the lint as violet or red, the actual colors are not the tones these terms typically indicate. Colors in cotton range from white through various shades of tan to brown to a reddish-brown or chestnut. Still, people call them *algodón morado* (purple cotton, Dominican Republic), *coton blanc* (white cotton, Dominica), *koton wuge* [*coton rouge*] (red cotton, Trinidad), *coton violet* (purple cotton, Haiti), and red cotton (Trinidad). That is also done in indigenous languages, as in Huastec where they recognize *thak kwinim* [*cuinim*] (white cotton, San Luis Potosí) and *tsokoy* (brown cotton, San Luis Potosí).

Cotton has been important to indigenous people for so long that many groups have simple terms for the plants. In the West Indies, the Arawak called it *ikálotopue*, and the Caribs say *maulu* [*mauru*] (Dominica, Suriname). The Carib word is considered cognate with the South American Tupí name *amandiyu-b* (Hodge and Taylor 1957). Mainland names include *ampi* (Morton 1981), *dehti* (Otomí, Veracruz), *ujilvʔi* (Tarahumara, Chihuahua), *mojofono* (Choco, Panama), *odigé* (Hispaniola), *pishm* [*pishten*] (Mixe, Mexico; *pishten-kiup*, the plant; *pishten-puih*, the flower), *tsiin* (Morton 1981), *tüdy* (Otomí, Veracruz), *uchto* (Morton 1981), *upsana* (Cuna, Panama), and *utju* (Morton 1981). However, a few languages have more interesting variants on their names. The Seri say *mooj* (cotton's fruit, Sonora). The Maya say either *xchup* (stuff, as in pillows, Yucatan) or *taman* (Yucatan). After the Spanish arrived, the Maya began calling sheep and lambs *taman*, the name they had long used for cotton.

Tribes in the United States were also familiar with cotton. They called it *naafalli* (Chickasaw), *o'fati* (Ofo), *pakaalihatka* (*pakaali*, cotton, *hatka*, white, Alabama), *paykahatká* (*payka*, cotton string, *hatká*, white, Koasati), *pakpvke-hvtke* (*pakpvke*, flower, *hvtke*, white, Creek), *pokpo* (Choctaw), *ptçato* (Bi loxi), *ro'ptini* [*ro'puhtini*] (Tunica),

*ujilvʔi*

*ta-čka hin* (*ta*, his, *čka*, white, *hin*, hair, Osage), *toki* (Pima), and (Cherokee). The historical record suggests that the plants were more important in the southwest than in the southeast. Indeed, archaeological data suggest that the genus was used comparatively late by southeastern tribes. No remains of cotton were found in early archaeological sites (Gilmore 1931, Whitford 1941). While Webb and Funkhouser (1936) did find cotton, they considered it intrusive.

The Aztecs were more direct with their naming. They said *ichcatl* (cotton) or *ichcaxihuitl* (thread herb, Náhuatl). Indeed, the fibers were treated by Hernández in 1651 as *ychcaxihuitl sen gossypio* (thread herb or *Gossypium*). It should be noted that the word *ichtli*, which is the root of *ichcatl* was derived from the Náhuatl word for fibers from *Agave*, their most important religious and utilitarian plant (see *Agave*).

The use as fiber in cloth sometimes overshadows the other uses Americans had for the cotton plants. Most important among those other uses was food. People throughout the Americas cooked the seeds and ate them. People in the Caribbean boiled the seeds before

eating them (Duke 1968). The Pima roasted the seeds and ate them like peanuts (Rea 1997). In the late 1800s and early 1900s, the Pima were still pounding the seeds with mesquite pods to make flour (Russell 1908). Castetter and Bell (1942) recorded a “sort of cake-like tortilla baked in ashes” that was made from finely ground and parched cotton seed and some other meal source. In 1899, American promoter David Wesson learned that the meal and oil from cotton seed was edible (when properly processed) and began selling it (as Wesson Oil) instead of throwing the “waste” from gins away (Davidson 1999). Wesson thus started the modern vegetable oil industry.

There are also numerous medical applications for cotton. The roots were formerly in the U.S. Pharmacopoeia as an emmenagogue, antihemorrhagic, and abortifacient. Gossypol is among the many compounds in the roots and seeds (Morton 1981, Hsu 1986). Although that chemical is mildly poisonous, and bitter, some consider the raw seeds aphrodisiac, expectorant, laxative, and nervine. Seeds are also prescribed to relieve headache (Duke 1968). Flowers, seeds, and leaves are used in Haiti whenever an emollient is needed, and the seeds are a remedy for dysentery (Beauvoir et al. 2001). A leaf decoction is given for flu, fever, cough, consumption, and chest colds. Flowers are used in tea for flu and colds (Bahamas). Leaves and flowers contain glycosides, quercimeritrin, isoquercitrin, and salicylic acid that have bacteriostatic, analgesic, and antipyretic actions (Ayensu 1981). So multiple are the uses of different parts of the cotton plant that we might almost conclude that the plant will cure virtually any malady. Various preparations have been used to treat abdominal complaints, bat bite, constriction of the ovaries, dermatoses, earache, eye problems, fever, flatulence, gastralgia, hemorrhoids, inflammations of the ganglia, parturition, rheumatism, sores, tachycardia, and urinary problems; it is also a “cacatrizant.”

Cotton is now considered an endangered species in Florida (Coile 2000). Among the causes of endangerment are habitat loss, and short-sighted, misdirected efforts by the U.S. Department of Agriculture (USDA).

When I first arrived in Florida in 1970, there were still people around who personally knew the “cottonpickers” the USDA had sent into the Florida Keys and southern coastal regions to “eliminate” cotton. Apparently, the USDA considered the wild cotton the “intermediate” source for the boll weevil that had for so long plagued the crop (Burke et al. 1986). What the USDA had not considered, among other things, was the distance between the wild cotton and that cultivated farther north. Elimination of one single cotton host so far from the centers of cultivation would have had little impact on the weevil problems for growers.

However, the cotton-pickers themselves were smarter than the bureaucrats in Washington, D.C. who hired them. Realizing that total elimination of the species from the state would also mean termination of their jobs, they always left some plants behind. They were even accused of destroying individual plants, and then scattering seeds from them as they left the site. Now, that is real planning for the future.

### ***Gouania*: Chew-Stick**

(In honor of French botanist Antoine Gouan, 1733–1821, professor of botany at Montpellier)

The first time I ever saw chew-stick (*Gouania lupuloides*) was in the Florida Keys. Back then, the only members of the Rhamnaceae that I knew were the temperate genera *Berchemia* and *Ceanothus*. These scrambling shrubs somewhat resembled *Berchemia*, but its fruits, with their usually three-winged margins, are markedly distinct. Worse, the “watchspring” tendrils baffled me. Eventually, I figured out the identity of the plants and their common name. Then I learned that Linnaeus did not know what to do with the species either, and so I felt a little better.

First, Linnaeus put the plants in *Paullinia* (Sapindaceae). Then 5 years later, in 1753, he called the chew-stick *Banisteria lupuloides*. Along with *B. lupuloides*, he described six others as *Banisteria*. Now we know that only *B. lupuloides* belongs to the Rhamnaceae, and the other six species are in the Malphigia

***Gouania lupuloides*.** a. Flowering branch, b. Fruiting end of branch, c. Flower, from above, d. Flower, side view, e. Flower, longitudinally dissected, f. Floral diagram. *Drawn by Priscilla Fawcett. From Correll and Correll 1982.*

ceae (in genera *Stigmaphyllon*, *Heteropterys*, and *Hiptage*).

Studying independently, Nicolaus Jacquin proposed the genus *Gouania* in 1763. Finally in 1910, Linnaeus’s species *lupuloides* (resembling the hop plant) was transferred to its proper place by Ignatz Urban, the tireless German student of West Indian botany.

*Gouania lupuloides* is a widespread member of the family, known from southern Florida, the Bahamas, the West Indies south to Grenada and from Mexico (Tamaulipas, Veracruz, Tabasco, Yucatán, Quintana Roo, Chiapas, Sinaloa, Colima, Nayarit, Guerrero) to Belize, El Salvador, Guatemala, Honduras, Nicaragua, Costa Rica, Panama,

Colombia, Brazil, Ecuador, Peru, and Bolivia. Our species is one of the 50 to 70 in a genus spread around the world in the tropics (Mabberley 1997). Most of the species are loaded with saponins and some are used as shampoos.

The species in Florida is best known as a toothbrush, as implied by the names chew-stick, chaw-stick, cho-bush, chow-bush, chew-wis (Florida, Puerto Rico, Jamaica, Barbados, Trinidad, Belize), and toothbrush tree (Trinidad). That the usage is old is suggested by its recording as chaw-stick in Florida in the 1800s (Chapman 1897). Surely, by that date, the application, if not the name, had been in place for several hundred years. Other languages say the same with *brosse à dents pays* (wild toothbrush, Haiti) and *limpia-dientes* (tooth-cleaner, Belize).

Although younger people may not be familiar with chew-sticks, they were the norm for the world before the Chinese toothbrush was introduced to Westerners after 1498 (Panati 1987). Chew-sticks to clean the teeth were recorded by the Babylonians in 5000 B.C. (Lewis and Elvin-Lewis 1977), and are still used by many poor people in developing countries. Chewsticks were apparently unknown in North American groups before Europeans arrived, and some think that they were introduced by Creole Africans from the Caribbean. Plants to be used as chew-sticks are carefully selected for a variety of characteristics, including foaminess, hardness, and bitterness (Lewis and Elvin-Lewis 1977).

Other names for *G. lupuloides* reveal different views. Some allude to learning about its use from the indigenous people, as in *bejuco [de] Indio* (Indian vine, Dominican Republic, Puerto Rico), *bejuco de la India* (Indian [woman's] vine, Dominican Republic), and *bo tán de indio* (Indian bud, Belize).

Due to the saponins, the plant has a soapy taste. Names reflecting that quality include *jaboncillo* (little soapy one, Colombia), *jaboncillo bejuco* (little soapy vine, Cuba), *liane-savon* (soap vine, Dominican Republic, Guadeloupe, Martinique), and soap-stick or soap vine (Puerto Rico). Presumably, *G. lupuloides* has been used for washing other items as the name soapstick implies, and as other species have. However, Cubans sometimes just think it tastes bad, as in *bejuco amargo* (bitter vine).

Because of clean teeth, the breath is refreshed, and people note that with *bejuco de sopla* (breath vine, Puerto Rico), *mascapelo* (mask it, Puerto Rico), *yerba buena* (good herb, Dominican Republic), and *bon bois* (good tree, French Antilles). At least in some cases, good breath improves interpersonal relationships, because it is also called *bejuco cundeamor* (count-oflove vine, Dominican Republic; name given to several vines, including *Momordica charantia* and *Ipomoea quamoclit*). Presumably, enhanced interaction also applies to *bejuco cuaresma* (abstinence vine, Dominican Republic), although the allusion is not clear. *Cuaresma* for Catholics is between Ash Wednesday and Easter, so maybe they "give it up" for Lent.

Some names simply refer to the appearance of the plant. Both *rabo de mono* (monkey tail, Nicaragua, Colombia) and white root (St. Thomas, Florida) are straightforward. On the other hand, what the plant has to do with cloth is not obvious in *bejuco leñatero* (linen vine, Cuba). The Maya think that the leaves resemble those of *Persea*, as in *somoak [om-ak, xomoak, xomak, xmak]* (*om*, avocado, *P. americana*, *ak*, twiner, Yucatan), and *x-pahua-ak* (*pahua*, common name for *P. schiedeana*, *ak*, climber, Yucatan). As avocado leaves are sometimes used in cooking, perhaps there is more to these names than a

physical appearance. In Belize, it is *baatch-pám* (*baat*, ax, *pám*, the toucan, *Aulacorhynchus prasinus prasinus*).

Quechua speakers also note the spiraled “watch-spring” tendrils and the twining stems. They say *chirapa-sacha* (*chirapa*, curly, *sacha*, wild plant, Peru).

The *Oxford English Dictionary* (1971) indicates that the first use of “chew-stick” for *G. lupuloides* was made by Peter Simmonds (1858). That may well be correct, but the name “chaw-stick” was well established before that. For example, Macfadyen (1837) praised the plant as follows: “In powder, it forms an excellent dentifrice; its aromatic bitter producing a healthy state of the gums, and the mucilage it contains working up by the brush into a kind of soap-like froth. A tincture also is prepared from it and much recommended, diluted with water, as a wash or gargle, in cases of salivation or disease of the gums. The principal use to which the Chaw stick is applied, however, is as a substitute for the tooth-brush itself. For this purpose, the extremity of a piece of branch, which is usually about the thickness of the little finger, is softened by chewing, and then rubbed against the teeth. In this manner, a tooth-brush and, with it, a powder are obtained equal, if not superior, to any in use in Europe.”

In Mexico, Central America, and the Caribbean, this species has long been a popular tooth cleaner. The stems are both aromatic and bitter, and those are traits preferred by many. According to Standley (1920–1926) and others, dried and powdered stems were not only used as dentifrices, but were exported from the West Indies and Central America to Europe and the United States. There is still a Jamaican mouthwash known as “Chew-Dent” that contains *G. lupuloides*.

Leaves have also been used to treat stomach problems (Mexico, Caribbean). Ash from the stems is powdered and placed on sores to speed healing. That ash and the leaves are said to be diuretic in Hispaniola (Liogier 1974), and therefore useful in treating dropsy. The stem powder is also thought to strengthen those who have been ill (Hocking 1997).

There are triterpenoid saponins in the plants that are at least partly responsible for its uses (Kennelly et al. 1993). Other species in the genus have other compounds (Nair and Madhusudana 1993). These chemicals are doubtless why several species other than *G. lupuloides* also are used. In the Americas, *G. polygama* has similar uses to *G. lupuloides*. That species is known in Venezuela as *rema* (oar), *bejuco de rema* (oar vine), and *reuma* (rheumatism). Surely, *rema* is an error for *reuma*. There is nothing about the plants that would suggest an oar unless it is an allusion to the winged fruits.

In the Old World, a poultice of *G. javanica* roots is applied to sores in southeastern Asia (Lewis and Elvin-Lewis 1977). Similarly, the pulped stems, roots, and leaves of *G. leptostachys* are used to treat skin diseases in Java (Lewis and Elvin-Lewis 1977). In addition, the bark is added to water used to wash the hair and kill parasites in Indonesia (Hocking 1997). In Fiji, *G. richii* leaves are pounded in water and drunk for stomachache, a use mirroring that of *G. lupuloides* in the Americas (Hocking 1997). According to the *Protocol Internationale*, the roots of *G. tiliaefolia* are a soap substitute and the leaves are recommended as a wash for ulcers in Indonesia (Hocking 1997).

Jamaicans not only use the stems to brush their teeth and as medicine, but they also use them in brewing beer, as a substitute for hops (*Humulus lupulus*). Indeed, the reason Linnaeus said it resembled hops (*lupuloides*) is because Leonard Plukenet in 1696 called the vines *Lupulus sylvestris americana* (wild American hops). Surely, he was reminded

of hops because the locals used the plants to brew beer. Clean teeth are important, but drinking beer takes priority.

Perhaps their use of chew-stick in brewing is why some Jamaican beers have such a distinctive taste. I wonder if the beer cleans the teeth while it pixilates?

### *Guajacum: Lignum Vitae*

(From *guayacán*, a Hispaniolan Taino name for the tree)

Almost halfway down the Florida Keys there is a small roadside marker that points to an island on the bay side and notes that it is the Lignum Vitae National Botanical Site. When I first started going there, not only was there no sign, there were no Park Service boats available to take visitors across the sometimes rough ocean. We either canoed over or rented a powerboat.

Regardless of how you arrive, getting to the island is stepping into a time machine and arriving in the early 1900s. The headquarters is a Key Largo limestone blockhouse literally bolted onto its foundation by steel cables. Using sane building methods, the first level of the house is open to allow hurricane waves to break underneath the occupants. Modern buildings in the Florida Keys show no such ecological awareness and foresight in planning.

Near the house on a trail through the forest is the former state champion lignum vitae (*Guajacum sanctum*). When I first saw this tree in the early 1970s, I was impressed with its size and main trunk about 9 inches in diameter. Then I saw the current champion on Totten Key—it has “small” branches considerably

*Guajacum sanctum*, a. Flowering branch, b. Leaf outline, c. Flower, side view, d. Flower, longitudinally dissected, e. Pistil, f. Petal, g. Floral

diagram, h. Fruit, closed (center) and open from side and above. *Drawn by Priscilla Fawcett*. From Correll and Correll 1982.

larger than the trunk of the Lignum Vitae National Botanical Site “giant.”

All things considered, it is a minor miracle that there are any lignum vitae trees remaining in Florida. As soon as the Spanish discovered the island of *Española* (modern Hispaniola), they contracted syphilis and took it back to Spain. By 1508, they had also taken back the local Taino remedy for the malady, tea from lignum vitae (Standley 1920–1926, Crosby 1972, Desowitz 1997). *Guajacum* was praised by Oviedo ([1526] 1969) and Nicholas Monardes in 1569 (Frampton [1577] 1925). Although few biologists know about it, there was already a medical book written on the syphilis remedy by 1540 (von Hutten 1540).

Whether or not the remedy helped the disease, the Fuggers of Augsburg, also noted as the most important bankers of the time, became the chief importers of the plants (Crosby 1972). Trees disappeared in the New World from much of their former range as the Fuggers commissioned shiploads to be brought to Europe to satisfy the market largely created by them. By the time the English surveyed the Florida coast, they commented that almost all the trees had been cut (Romans [1775] 1961).

*Guayacán* (Caribbean, Mexico, Guatemala, Nicaragua) is a Taino name taken from Hispaniola (Oviedo [1526] 1969); Oviedo also wrote it as *guayacá* and *guayacan* (without accent). Monardes (Frampton [1577] 1925) wrote *guaiacan*, but etymologists assert that the aboriginal Caribbean name was *guaiaic* or *guayaco*. The name also has been spelled *Guaiacum* in much of the scientific literature, although Linnaeus wrote *Guajacum*.

The common names now used are *game bâlard* (false guaiac, Haiti), *gaïe blanc* (white guaiac, Haiti), *game cardasse* (comb guaiac, Haiti), *game femelle* (female guaiac, Haiti), *gayac* (Haiti), *guayacabillo* (little guayac), *guayacán* (Taino, Caribbean, Mexico, Guatemala, Nicaragua), *guayacán bastardo* (false guaiac, Dominican Republic), *guayacán blanco* (white guaiac, Cuba, Puerto Rico), *guayacán de vera* (true guaiac, Puerto Rico), *guayacáncillo* (little guayac, Dominican Republic, Puerto Rico), *pyé gayac* (country guaiac, Haiti), *wajakka* (Abaco, Bonaire, Curaçao), *wajakaa maatsjoe* (forest guaiac, Dutch Antilles), *wayaca* (guaiac, Dutch Antilles), and *wayaca shimarón* (wild guaiac, Dutch Antilles). *Vera* [*bera*, *beera*] (Dominican Republic, Dutch Antilles) seems to be a shorthand form of *guayacán de vera*.

Other than the Taino name, the first Spanish reports called the trees *palo santo* (holy wood, Mexico Puerto Rico). The name holy wood was applied early and is used as the Spanish name by both Oviedo ([1526] 1969) and Monardes (Frampton [1577] 1925). As late as 1651 Hernández devoted a chapter to *Hoaxacan, sen Ligno Sancto* (guaiacan or holy wood) (Standley 1920–1926). The French use the same name and call it *bois saint* (holy wood, Haiti), and the Portuguese say *pão santo* (holy wood, Brazil). Those names were used because of belief in the Doctrine of Signatures, which maintains that when God sent a pestilence to humans, He also sent a remedy from the same region (Crosby 1972). All but the best physicians of the time thought that *palo santo* was that remedy. It

turned out that the merchants were touting a false remedy and people continued to die of the disease (Crosby 1972). Then as now, *caveat emptor!*

The first record in English of the common name *lignum vitae* (wood of life, Latin) appeared in 1594 for the wood. Then, in John Gerarde's *Herball* of 1597, the name was applied to the tree itself. These names are dominant in English, but some of the variants are almost unrecognizable. For example, in the Virgin Islands they may be called *lingy whity*, *lingy vity*, or *niglum wity*. Those are attempts by people of African origin to pronounce the Latin words. Some still use a translation of the Latin and call it tree of life (Haiti).

When syphilis first appeared in Europe, physicians did not recognize the malady. Because syphilis began with ulcers and sores, Europeans compared it with a disease they knew, the "pox" (from the 1300s, applied to chicken pox). The French called it the Italian pox, and the Italians called it French pox. Others said it was the pox of Naples, and the medical literature called it the Great Pox. Indeed, people should have followed Oviedo's ([1526] 1969) recommendation to call it the "Pox of the Indies," because each nationality thought (probably correctly) it contracted the malady from the other. These old names remain in *Pockholz* (pox tree, German) and rarely in English as pockwood tree.

Monardes (Frampton [1577] 1925) had already noted that there was one species (*G. officinale*) on Hispaniola, and another on St. John near Puerto Rico (*G. sanctum*). We now know *G. sanctum* from southern Florida, the Bahamas, Cuba, Hispaniola, Puerto Rico, Yucatan, maybe Veracruz and Tabasco, Guatemala, Honduras, Nicaragua, and Panama. Subsequently, another species was found on the Mexican mainland. The Mexican species is *G. coulteri*, and grows from Sonora to Oaxaca. That tree also quickly acquired the Taino name *guayacán*. It too is called by the original Spanish names *árbol santo* (Puebla) and *palo santo* (Oaxaca, Jalisco). Indigenous people also had names for it. Those names include *matlaquahuil* (maguey or *Agave*+tree, Náhuatl), *yaga-na* (*yaga*, tree, Zapotec, Oaxaca), *yutnu-tandaa* (Mixtec, Oaxaca), *yúyaguo* (Mayo), *moeni* (Seri), and *huha'awo* [*hyuawo*] (Yaqui).

In addition to being considered antisypilitic for so long, resin from the tree was considered an effective treatment against gout, rheumatism, scrofula, and cutaneous diseases. Many consider the resin stimulant, alterative, diaphoretic, and purgative in large doses. Indeed, *Guajacum* was in the U.S. Pharmacopoeia until the 1920s. Although the bark and wood contain alpha-guaiaconic, guaiaretic, and other acids, enedione lignan, furanoid lignan, prosapogenin, sapogenin, saponins, and vanillin (Kratovich 1971, Majumder and Bhattacharyya 1974, 1975, Ahmad 1984a,b, 1985, 1986a,b, 1989b,c, 1990a,b, Almeida et al. 1996, Hocking 1997), the medical application is no longer accepted in the United States or Europe. *Lignum vitae* is subject to legal restrictions in some countries (Swerdlow 2000).

Throughout the Caribbean *Guajacum* is still used against venereal diseases and considered stimulant and sudorific, traits attributed to the resin by the pharmaceutical trade (Hocking 1997). Tea of the wood is used against skin diseases, rheumatism, gout, asthma, scrofula, and chronic lung problems (Liogier 1974, Beauvoir 2001). The resin (guayacol is red-brown, changing to blue or green when acidified) is used to strengthen gums and is applied to relieve toothache. The resin is also applied externally to skin diseases, and taken orally for arteriosclerosis, rheumatism, blood pressure regulation, and gout. Bark infusions are used against chills, grippe, rheumatism, and scrofula.

Resin (*guaiaci resina*) is still one of the principal reagents in tests for occult blood (Hocking 1997). Moreover, certain extracts show promise as a molluscicide (Almeida et al. 1996), and the boiled bark is a fish poison (Petersen 1974).

Wood from all species is strong, hard, heavy, resinous, and lubricant. The wood is used for rollers, maces, pulley sheaves, deadeyes, bandsaw guides, awning rollers, furniture casters, mallets, bowling balls, turned items made on lathes (Liogier 1974), and even railroad ties (Standley 1920–1926). It is famous for making self-lubricating, sea-worm resistant bearings and bushing blocks on ships. The heavy wood (specific gravity 1.2 to 1.3) sinks in seawater.

After surviving the harvesting of the Fuggers of Augsburg, the trees in Florida are now threatened by both habitat loss and a scale insect. Although the scale has been attacking the trees since at least the late 1960s, the species doing the damage was only identified in the early 1990s (Williams 1993). An endemic insect that apparently lived as a minor pest of the trees until recently now threatens to destroy plants that gave the name to a Florida botanical site.

### *Guapira*

(J.F.Aublet named the genus from an indigenous word, perhaps from Tupí, *wa'bi*, to eat, *rob*, bitter)

*Guapira discolor*. Drawn by  
P.N.Honychurch.

***Guapira discolor*** (two surfaces of the leaves unlike in color)  
*barrehorno* (*barre*, from *barrer*, to clean off vegetation, *horno*, oven, but also “at the most cious time,” Cuba, Puerto Rico)  
beef-[tree, wood] (Bahamas, Florida)

blolly (shortened form of “loblolly,” Florida); narrow-leaf blolly (Bahamas)  
 cabbage-tree (Cayman Islands; could the leaves be edible?)  
 pigeon-berry (Bahamas)

Professor of medicine and botany at Halle, Germany, Kurt Sprengel (1766–1833) called this Caribbean species *Pisonia discolor* in 1825. It was not until 1968 when Elbert Little moved the species to *Guapira*, a genus Aublet had created in 1775. Now there are about 70 species in the genus (Mabberley 1997).

Berries are edible and the wood is useful (Little and Wadsworth 1964).

### ***Guettarda*: Velvet Seed**

(To commemorate the French physician Jean Étienne Guettard, 1715–1786)

Both species of velvet seed (*Guettarda elliptica*, *G. scabra*) historically grew from about Fort Lauderdale (central Broward County) south along the eastern Florida coast almost to Key West (Little 1978). In addition to that, there is one small disjunct population in southern Martin County. This colony lies 40 to 50 miles north of the historical range of the others, although urbanization has now made the gap even larger. Even stranger for this shrub, which is normally a pine rockland species farther south, it grows with gumbo limbo (*Bursera simaruba*) in Martin County. This association also has other disjunct and unusual species for the region and former County Commissioner Maggy Hurchalla was finally able to have the unique site made into the Rocky Point Hammock Park.

Outside of the Miami-Dade County parks, the Everglades National Park, and the pine rocklands in the lower Florida Keys, few people in Florida know these plants. Where they occur, they are often abundant shrubs. Deeper into their range, through the Bahamas, the West Indies from Cuba to Trinidad and some of the other islands off northern South America, people know the plants well. There they not only know them from their red fruits, but they also compare them with other plants. They compare *G. scabra* with the guava (*Psidium guajava*) by calling it *bois goyavier* (guava bush, Guadeloupe, Martinique), *goyavier bâ-tard* (false guava, Guadeloupe, Martinique), *guayabillo blanco* (little white guava tree), and wild guave (Dutch Antilles). They distinguish *G. elliptica* with

***Guettarda*.** *Guettarda elliptica*. From Little and Wadsworth 1964. *Guettarda scabra*, a. Branch with flowers, b. Flower from above, stigma apparent, c. Flower from above, stigma not apparent, d to g. Flowers longitudinally dissected to show variation in style length, from short (d) to long (g). h. Floral diagram, i. Fruiting branch. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

*guayabillo prieto* (black little guava, Mexico). For some reason they compare *G. scabra* with *chicharron de monte* (wild [mountain] peas, Cuba) and juniper (Grenada).

These two species sometimes are also compared by other people. In English, *G. elliptica* is usually called velvet seed (Florida, Puerto Rico), while *G. scabra* is rough velvet seed (Florida), roughleaf velvet seed (Florida, Puerto Rico), or velvet berry (Bahamas, Puerto Rico).

Inexplicably, in the Virgin Islands *G. scabra* is called greenheart. That common name elsewhere is given to *Chlorocardium rodiaei* (also called *Nectandra rodiaei* and *Ocotea rodiaei*, Lauraceae) of Guyana, sometimes called Demerara greenheart (Gérard et al. 1996). That species is a large rainforest giant that provides one of the main timbers exported from that country. It is a heavy timber, resistant to termites and borers. It is a mystery how the people in the Virgin Islands came to use the same name for *G. scabra*, which is a small tree of moist coastal woodlands on limestone, reaching a height of only 10 to 15 feet and only about 4 inches in diameter. Maybe it also has green heartwood?

Wood of these small trees is light brown, hard, heavy (specific gravity ~0.8), and fine textured (Little and Wadsworth 1964). The stems are used for stakes and fuel, and for other items like some of its related species.

Both *G. elliptica* and *G. scabra* are called *cucubano*, as are other species in Puerto Rico. *Guettarda scabra* is just *cucubano* or *palo de cucubano* (*cucubano* wood), while *G. elliptica* is *cucubano liso* (smooth *cucubano*). This is a Taino word, referring to both a lightning bug and an owl. *Cucubá* still is the Puerto Rican screech owl (*Otus nudipes*) (Raffaele 1983). This is the screech owl on that island, and its counterpart on Cuba is the bare-legged owl (*Gymnoglaux lawrencii*). On both islands these birds are also called “Cuckoo Birds” because their “love call is the mellow, sonorous ‘coocoo’” (Grossman and Hamlet 1964). The name *cucubá* may be an onomatopoeic imitation of the call.

What relationship the plant might have with a bird is obscure. The only apparent possible relationship is that the birds are active at night, and the plants flower then. In the evening the 3/4-inch-long flowers perfume the air with their heavy scent and attract half-blind sphinx moths (*Perigonia lusca*). That moth was considered rare when Holland (1965) studied the insects of the state. The moth is still known only from Palm Beach and Miami-Dade Counties (Struttmann 2002), and has been found feeding as a larva on many members of the Rubiaceae deeper within its range. Larvae have also been raised on *Ilex krugiana* (Aquifoliaceae), an unrelated species.

Could it be that someone thought the moth visitors were really birds? Is that why both are called *cucubano*?

Names for the two Florida species diverge at this point. Fewer names are known for *G. elliptica*. Several of its names refer to a cross, including *crucecilla* (little cross, Mexico), *cruceto negro* (black little cross, Venezuela), and *crucillo* (little cross, Mexico). That may be an allusion to medical use following the Doctrine of Signatures. There are other species in other families that have the cross allusion in their names, and all are used for some remedy.

Some of the other names for this species are particularly curious. In Venezuela, it is called *cabrito* (kid or young goat). All that is recorded about it there is that the fruits are edible. However, it makes one wonder if “kids” (humans and goats) are among the only ones eating those fruits. Also in Belize it is prickly wood, and in Venezuela it is called *punteral* (thicket of “stickers”). If you go walking in a patch of it, the stiff branches certainly would make those names appropriate. Pickle-wood (Belize) must be an error for “prickle-wood.”

Oddest of names for *G. elliptica* are *cuero de sabana* (savanna skin, Cuba). No tannin content has been recorded or any use for tanning, so the “skin” in the common name must be the thick leaves. If you really work at it, they do resemble leather. *Cagüilla* (Cuba) must be another of the Taino names whose meaning, beyond the identity of the plant, has been lost.

The rough leaves of *G. scabra* were the source of its species name (*scabra*, rough), and the vernacular *serrasuela* [*serrazuela*] (little saw, Puerto Rico). That name is reminiscent of roughleaf velvet seed in English. Perhaps the name *carapacho* (carapace of crustaceans, Cuba) also alludes to the abrasive surface as in the carapace of the spiny lobster (*Panulirus argus*).

In the Bahamas, *G. scabra* is called gnat wood (Bahamas). Since there are often gnats around in the summer when the plants flower, that is a reasonable name. The species is

called *palo de dajao* (*dajao* is a river fish) in Puerto Rico, so maybe it has been used as a fishing pole.

There do not seem to be many common names alluding to medicinal uses. Since the plants have been used widely as aphrodisiacs, that is somewhat surprising. Surely the names bat-leaf (Bahamas), blue copper (Tobago), *bois madame* (lady tree, Guadeloupe, Martinique, St. Lucia), *bois noire* (black tree, St. Lucia), candlewood (Antigua, Dutch Antilles), crawwood (Barbuda), and four-man's strength (Bahamas) refer to giving "energy" or "restoring strength" for love-making. That application is apparently the most common use of any of the American species of *Guettarda*. Sometimes *G. scabra* is mixed with banana (*Musa×paradisica*), or the leafy stems are tied in bundles with bark of *Bourreria ovata* and *Tabebuia heterophylla* and boiled to produce an aphrodisiac decoction. Beyond that, there seems to be little in the way of medicinal use for the genus in the Americas.

Related species contain a variety of chemicals, including essential oils (*G. poasana*, Costa Rica), glycosides (*G. platypoda*, *G. trimera*, New Caledonia), quinoline alkaloids (*G. ovalifolia*, Puerto Rico; *G. noumena*, New Caledonia), terpenoids (*G. angelica*, Brazil), and indole alkaloids (*G. acreana*, Ecuador; *G. trimera*, New Caledonia). Among the laboratory results exhibited by these compounds are activity as antiviral agents, antimicrobial agents, inhibitors of yeast, and as antispasmodics (Sousa et al. 1984, KanFan et al. 1985, Matos et al. 1986, Aquino et al. 1988, 1989a,b, Cotterill and Fergusson 1993, Jiang et al. 1994, Montagnac et al. 1997, Capasso et al. 1998). There seem to be no studies of either of the Florida species, but presumably they contain related chemicals.

Linnaeus created *Guettarda* in 1753. The only species he knew was *G. speciosa*, from Java; it also occurs elsewhere in Asia and in Madagascar. That species is a noted source of "zebra wood," although wood sold under that name also comes from several other genera (Uphof 1968). The genus *Guettarda* is now known to contain about 80 species spread around the tropical coasts of the world (Mabberley 1997). Several of them have edible fruits, and maybe that is as good a human use as any—especially on a hot, muggy day in the rockland flatwoods where these shrubs grow. However, Floridians might introduce the trend of use of *G. speciosa* from the Pacific Islands. There, girls put them in their hair for perfume, and Fijians and Samoans make them into necklaces or leis.

### *Guzmania*

(Named by Hipólito Ruiz and José Antonio Pavón for Anastasio Guzman, a Spanish naturalist of the 1700s)

#### *Guzmania monostachya* (one-spiked inflorescence)

air plant

*asômco:bî* (big Spanish moss, Mikasuki); *assonakko* [*assonrakkô*] (*assúnwv*, Spanish moss, *takko*, big, Creek)

*curujey bonito* (pretty airplant, *curujey* is the Taino word for epiphytes, Cuba)

*piña de agua* (water pineapple, Dominican Republic)

*tinaja* [*tinajita*] ([little] well, Dominican Republic)

***Guzmania monostachya*.** a. Flowering and fruiting habit, b. Floral bract, c. Flower and bract, side view. d. Flower and bract, longitudinally dissected, e. Fused anthers, f. Floral diagram, g. Fruit. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

Linnaeus described *Renealmia monostachya* in 1753. That genus belongs in the Zingiberaceae. When people later looked at the plants, they realized that the species belonged in the Bromeliaceae. So, New York Botanical Garden's Henry Hurd Rusby (1855–1940) and professor at Königsberg Carl Christian Mez (1866–1944) moved the species to *Guzmania*, which had been described in Peru in 1802. Smith and Downs (1977) included 131 species in *Guzmania*, all endemic to the American tropics.

Seminoles used the water trapped in the base of the plants for cooking during the dry season (Sturtevant 1955). The common names suggest that other people used the water in the same way.

### ***Gymnanthes*: Crabwood**

(From Greek *gymnos*, naked, and *anthos*, flower)

In South America, the early explorers of the French Guiana region found Cariban people calling one tree *carapa*, and another *caraipé*. It was probably inevitable that English-speaking people misunderstood these indigenous names, and thought they said “crab.” However, that is what appears to have happened with one or both of these words.

The first variant seems to have been *carapa*, the indigenous name that also gave us the Latin name of a tree related

***Gymnanthes lucida*.** a. Branch with catkins, b. Leaf primordium, with inset of margin, and marginal gland, highly magnified, c. Mature leaf, with inset of margin, and marginal notch, highly magnified, d. Leaf base. e. Single flowering branch, with lower flowers expanded, f. Pistillate flower, longitudinally dissected, g. Floral diagram of staminate flower, h. Floral diagram of pistillate flower, i. Fruit on twig, j. Fruit. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982.

to mahogany and China-berry, *Carapa guianensis* (Meliaceae). These are large trees in the Guianas and their fruits wash out into the ocean and eventually drift onto the beaches of Florida. They only flower about once every 5 years, and trunks are harvested for timber (Gérard et al. 1996). The seeds serve as fish bait, as a source of *andiroba* (from

*adi'roba*, bitter oil, Tupí), which is an oil that is used in lamps, soapmaking and candle-making, as a medicine against arthritis and throat infections, and as an insect repellent, and the oil was formerly used by head hunters in shrinking heads (Hocking 1997). The common names for the wood includes bastard mahogany, *andiroba*, *tallicona*, and—you guessed it—crabwood.

Florida's crabwood is not the same plant at all, but a small tree in the Euphorbiaceae known scientifically as *Gymnanthes lucidus* (*lucidus*, shining). The genus and species were created by Olaf Swartz in his *Nova Genera et Species Plantarum* (New Genera and Species of Plants) published in 1788. Another version is that crabs eat the bark and berries in the Bahamas, and that gave it the name (Von Reis 1973).

This is one of those confusing cases where the morphological similarities cause problems in interpretation of generic limits, and books keep changing names back and forth. Britton and Millspaugh (1920), Small (1933), and Leon and Alain (1957–1963) used the name *Gymnanthes lucidus*. Then, because of studies done on Jamaican and Bahamian plants (Adams 1972, Gillis 1974), the name was changed to *Ateramnus lucidus*. Subsequently, Tomlinson (1980) and Correll and Correll (1982) used *A. lucidus* for the trees. Finally, Webster (1983) examined the situation and discovered that *Ateramnus* was actually a synonym for *Sapium*. That revelation caused *Gymnanthes lucidus* to be restored.

Regardless, the word *Ateramnus* proposed by Patrick Browne in 1756 during his sojourn in Jamaica gave an apt commentary on these plants. Browne based the name on the Greek word *ateramnos*, meaning hard or stubborn. Almost certainly, he was referring to the dense (specific gravity 1.1), finetextured trunk with its white sap wood and olive to dark brown heartwood (Little and Wadsworth 1964).

Florida's *G. lucidus* ranges through the Greater Antilles, the Lesser Antilles to Guadeloupe, and is also in Yucatan, Guatemala, and Belize (Leon and Alain 1957–1963, Adams 1972, Correll and Correll 1982, Balick et al. 2000). There are 15 species in the genus, with 5 in Jamaica, 2 in Nicaragua, and the others throughout Mesoamerica (Mabberley 1997).

Three variants of the common names seem to have arisen from confusion or comparison with the Guyanese *carapa*. These are “crab bush” and “mañ crab bush” (British Antilles) and “crabwood” (Bahamas, Jamaica, USA, Guyana). Even these may be references to the similarity of the wood to a formerly betterknown plant. The following common names are comparisons or descriptions of the wood. These are *bois marbre* (marbled tree, Haiti), *bois madre* (maybe a corruption of *bois marbre*, otherwise mother-wood, West Indies), *bois vert* (green wood, Lesser Antilles), *branquillo* (little white one, Brazil), goat wood (St. John), false lignum vitae [lignum-vitae] (Belize), *Juan prieto* (black John, Dominican Republic), *palo de hueso* (bone wood, Dominican Republic), oysterwood (USA), Cuban oysterwood (Bahamas), and shiny oysterwood (USA). In Puerto Rico and elsewhere the wood is used for fence posts, canes, handles, backs of brushes, mirrors, and ornamental articles made by woodturning (Little and Wadsworth 1964).

There are even some names that compare these small trees with tobacco, as *palo de tabaco* (tobacco wood, Dominican Republic), *tabaco* (tobacco, Puerto Rico), and *tabacón* (big tobacco, Dominican Republic). While it seems unlikely, the leaves may have been used as tobacco substitutes. If that is the case, the people calling them by those names and

using them were totally unaware of a long-term error in botanical literature. Beginning at least in the 1920s, perhaps with Paul Standley (1920–1926), there are notes that the trees contain milky sap that is extremely poisonous. Either that was the source of the common name poisonwood (USA) or the plants were confused with *Metopium*. That statement from Standley, who spent thousands of hours in the field in Middle America, is almost impossible to believe. He was an extremely astute botanist who listened to and critically examined the information provided by helpers and consultants from nearby villages. Yet, his *Trees and Shrubs of Mexico* is the first place that I have found this mistake. Instead, as Adams (1972) and others have pointed out, the sap in these plants is not milky, but clear. It never caused problems for me, and presumably did not for others, because there is no credible account of it in the literature. Instead, the erroneous comments from the 1920s were repeated by Standley and Record (1936) and Little and Wadsworth (1964).

Some of the other names refer to other aspects of the plants. These include *pij* (probably a simple Maya term, Guatemala), *ramón* (much-branched, Puerto Rico), and *haite* [*aité*, *aiite*, *aite*, *aiti*, *yaití*, *yaibi*] (*haytí*, high land, Taino, Cuba, Puerto Rico, Mexico), and *yaiti macho* (male *yaití*, Cuba). *Capixava* (from *kapi'xawa*, planted place, Tupí, Mexico, West Indies) is attributed to *G. lucidus*, but in Brazil, it is the name of *Sebastiania brasiliensis*.

Other names refer to other aspects of the plants, particularly fruits. These are *aceitillo* (little oily one, Cuba), *granadillo* (from *granada*, the pomegranate, because of the red color), and what seems to be simply a spelling variant, *greaddillo* (little pomegranate, Dominican Republic), *granadilla boho* (maybe *boho* is a corruption of *bohio*, house, Taino, Dominican Republic), *huevo de chivo* (goat testicle [egg], Dominican Republic), and *jabacón* (perhaps a transcription error for *tabacón*, Dominican Republic).

In the Bahamas, including the Turks and Caicos Islands, leaves are chewed or branches boiled and the decoction taken for stomachache and “griping” (Von Reis 1973, Morton 1981). Whole small plants are boiled, root and all, and the liquid used to stop diarrhea or relieve other stomach problems. To cure piles, leafy twigs are boiled with *Bourreria succulent* a leaves, root of *Zanthoxylum coriaceum*, root of *Chiococca alba*, leaves of *Cassia bahamensis*, and aboveground parts of *Turnera ulmifolia* and *Capraria biflora*. All are bundled together and tied. The decoction is said to be an “unfailing remedy.” In Cuba, a decoction of the bark is used against toothache (Roig 1945).

Taken individually, the common names are similar to those of many other Caribbean species. However, some may suggest a use not recorded in the literature. Given the small fruits (~10 mm across), the name *huevo de chivo* seems to come from an exaggerated imagination, or a snide comment. However, when it is compared with goat wood, oysterwood, and shiny oysterwood you begin to wonder if the trees were not used as aphrodisiacs.

# H

## *Habenaria*

(Carl L. von Willdenow named the genus from Latin *habena*, a strap, holder, rein; the lip is usually trilobed and always spurred)

***Habenaria floribunda*** (many-flowered) (= *H. strictissima* var. *odontopetala*)

*clavo cojincillo* (*clavo*, club, *cojincillo*, pad, Veracruz)

false rein-orchid

*hihkiti:nayikci* [*hihkitiinayikci*] (horned-owl medicine, Mikasuki);

*istikinihiliswâ* (*estekene*, hornedowl, *heleswa*, medicine, Creek)

long-horned orchid (the “horn” is the spur)

mignonette orchid (“mignonette” from feminine of *mignonet*, dainty, French, and Middle French *mignon*, darling; in English by 1752)

*oek ahyetche* (water medicine, Mikasuki)

tooth-petal orchid

*Habenaria* was segregated from the other terrestrial orchids by Willdenow in 1805. Then John Lindley described *H. floribunda* in 1835. There are now about 600 pan tropical and subtropical species in the genus (Mabberley 1997).

The Seminoles use the plant in funeral ceremonies to send off spirits and in a medicine to strengthen medicine men (Sturtevant 1955, Bennett 1997). The Zoque-Popoluca in Veracruz use it to stop vaginal bleeding (Vásquez and Jácome 1997).

## *Hamamelis*

(Ancient Greek name of the medlar, *Mespilus*, or some similar tree; reapplied to the American plants)

***Hamamelis virginiana***. From Sargent 1905.

***Hamamelis virginiana*** (of Virginia)

[spotted, striped] alder

*bwaoke'it* (no heart wood, all white, Potawatomi)

*café du diable* (devil's coffee, Quebec)

*iyonabi* (*iyon*, from English iron?, *abi*, tree, Choctaw)

pistacio (first used as the genus by Plukenet in 1696, and then as a common name by C.S. Rafinesque in his *Medical Flora*, 1828)

tobacco-wood

winter-bloom [winterbloom]

[American, common, southern] witch-hazel [witchhazel] ("witch," or "wych" applied by 1540s, in this case means having pliant stems; see *Ulmus*; "hazel" is a name applied to the fruits of *Corylus* since about A.D. 700; derived from Old Teutonic *hasaloz*, and cognate with Latin *corylus*, helmet, and perhaps Gaelic *coll*); snappy [snapping] hazel

*Zaubernuss* (magic nut, German)

"Witch-hazel" began as a common name for European plants. The first appearance in print was in Shakespeare's *Henry VIII* where he wrote, "That everie bowyer...for every bowe that he maketh of Ewe, make fower other bowes...of Elme, wyche hasill, ashe, or other Wood." Gerarde ([1597] 1975) equated the term "Witch hasell" with the hornbeam (*Corylus*), and it too is famous for its pliable branches (Edlin and Mitchell 1985, Vickery 1995). It is not clear which species Harriot was talking about in what is now North Carolina. When he wrote in 1588 that the Carolina Algonquians had "wich-hazel, whereof the inhabitants vse to make their bowes" (Harriot [1590] 1972). The first equating of *Hamamelis* with witch-hazel was in 1760 (OED 1971).

In the Americas, *Hamamelis* branches are preferred as "witching-rods," "dowsing-rods," or "*virgula divina*" The translation of divining rods [staffs, sticks, wands] (appeared by 1656, translated from Latin) indicates the use in locating water or mineral deposits. However, according to Rosengarten (1984), the preferred plant in England has been the hazel, *Corylus*, since the Dark Ages (A.D. 476–1000). Panati (1987) places the date in the 7th century A.D.

Divining with hazel rods probably originates with Greek mythology when Apollo and Mercury, the two sons of Jupiter, exchanged gifts. Apollo received a tortoise-shell lyre; he used its music to release the artistic spirit in humans. Mercury got a winged wand made of hazel-wood whose touch helped people express their thoughts through words. A winged hazel rod entwined with snakes became the symbol of communication. Romans also revered *Corylus*, and hazel torches were burned on wedding nights to ensure a happy marriage (Rosengarten 1984). The use of a divining rod made from a hazel branch probably can be traced back to mythology.

Some still practice this "art" today in both America and the Old World. Those who use this technique, called dowsers (etymology unknown), hold a forked branch in both hands. They say that the branch turns and points to the earth at the place where buried treasure, veins of precious metals, and streams of subterranean water are to be found. The Mohegans, apparently learning the technique from the Europeans, used this method to try to find water and buried treasures (Moerman 1998).

Rafinesque called *Hamamelis* "pistacio." The learned Englishman John Lindley said the seeds were edible (Hedrick 1919). *Hamamelis* seeds approach 10 mm in length, and

have been eaten by some tribes (Yanovsky 1936). They were considered sacred beads by at least the Menomini (King 1984).

Overshadowing the dowsing potential of the shrubs is their medicinal use (Moerman 1998). The Cherokee took an infusion to treat fever, colds, sore throat, and tuberculosis. They also used it to wash sores and to alleviate other skin problems (Hamel and Chiltoskey 1975). The Iroquois made extensive use of the shrubs. They used a twig infusion to stop bloody dysentery and cholera and a poultice of branches for asthma, colds, coughs, consumption, and heaves, or drank a decoction. Decoctions or infusions were used to treat arthritis, kidney problems, and toothache, and to purify the blood. A decoction of *Hamamelis* and other plants was used to prevent hemorrhage at childbirth and as an astringent applied to external wounds and bruises. Although it was said to stimulate appetite, a bark decoction was emetic. The Ojibwa used an infusion for skin troubles and to wash sore eyes, and they took it as an emetic in cases of poisoning. The Menomini made a decoction and rubbed it on their legs to keep them supple during sports and to relieve back problems. The Potawatomi put twigs in sweat baths to relieve sore muscles (Smith 1933).

Medicinal extracts, including lotions and salves, still are made from leaves, twigs, and bark, now by distillation (Vines 1977, Foster and Duke 1990, Swerdlow 2000). The products are used to treat bleeding, lessen inflammation, and decrease mucous secretions. Tannins in the leaves and bark are thought to be responsible for the astringent and hemostatic properties (Foster and Duke 1990, Duke et al. 2002).

### ***Hamelia*: Firebush**

(Named for the French forester, agronomist, and *Inspecteur generate de la Marine*, Henri Louis du Hamel du Monceau, 1700–1782). An old adage says that you remember something longer if you have to figure it out for yourself. What usually is not included is that you remember it better if you make a fool of yourself in the process.

Some time after moving to Florida, I decided that I wanted a small pollination garden outside one of my windows. I planted both firebush (*Hamelia patens*) and necklace pod (*Sophora tomentosa*)—nice complementary red (bird) and yellow (bee) flowers. It seemed that those colors would attract any pollinators around, whether vertebrate or invertebrate.

I watered the plants faithfully for a few weeks. Then, I noticed that the more I watered, the more the *Hamelia* improved and the *Sophora* declined. So, changing tactics, I watered less often. As the soil dried out, the *Sophora* brightened up and the *Hamelia* began to wilt. There was obviously an error in my strategy. Finally, it occurred to me that *Sophora* always grows in dry beach areas and *Hamelia* in moist-to-wet hammocks and swamps. Together, they were not going to work, so I quit watering. The *Sophora* thrived, and of course, the *Hamelia* died.

***Hamelia patens***, a. Branch with flowers, b. Node showing stipules, c. Flower, from above, d. Flower, side view, e. Flower, longitudinally dissected, f. Floral diagram, g. Fruits. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

There are benefits to and costs for everything. Firebush in the major part of its range (the Bahamas, West Indies, from southern Mexico to Peru and Paraguay) depends largely on hummingbirds for pollination. Southern Florida has no resident hummingbirds, and only some of the firebush plants can be pollinated by the overwintering winged jewels, the ruby-throat (*Archilochus colubris*). Instead, the plants “use” butterflies as alternate pollen vectors. I suspect that many of the plants are also facultatively self-pollinating (autogamous), but I have seen no studies on that topic.

Within the areas where hummingbirds are the pollinators, even they have costs and benefits. Mites living in the flowers are transported from plant to plant by the visiting birds (Colwell 1995, Paciorek et al. 1995). Not only do the hummingbirds obtain the reward of nectar and the energy from it, but the mites are moved around and the plants are pollinated. There are negative impacts on both the plants and the birds to having the parasitic mites involved, but they are not so great that they impede reproduction.

To the birds and to humans, the most eye-catching aspect of *Hamelia* is the red color—in leaves, flowers, and fruits. Indeed, that color is the reason for the common name firebush. Some allusion to the color is found in about half the vernacular names for the species. Some compare *Hamelia* to other red plants, like *achiotillo Colorado* (little red achiote, Honduras). *Achiote*, also called *annato*, is *Bixa orellana* (Bixaceae), perhaps the most commonly used red pigment in the Americas. Others think the flower cluster

resembles a coral necklace and say *bois corail* (coral tree, French Antilles), *corail* (red one, Haiti), *coral* (red one, Cuba, Honduras), *coralillo* (Cuba, El Salvador, Costa Rica, Colombia), *coralito* (little red one, Venezuela), *fleur corail* (red flower, Haiti, Guadeloupe, Martinique), and *palo de coral* [*pal o coral*] (red tree, Cuba).

Still other names make comparisons to a variety of items. In different places it is *cuetillo* [*cohetillo*] (little rocket, probably fireworks), *clavito* (little heart, Guatemala), *coloradillo* (little red one, Honduras), *cresta de gallo* (rooster comb, Colombia), *palo camarón* (shrimp tree, Costa Rica), Polly red head or red head (Belize), red berry (Panama), *sancocho* (parboiled meat, El Salvador), or just scarlet bush (Puerto Rico, Panama).

For some reason, there also is an association with the color blue, and people say *añileto* (little indigo [*Indigofera*], Costa Rica) or *azulillo* (little blue one, Costa Rica). Alluding to a medical use, it is called *bálsamo* (balsam, Puerto Rico), *bálsamo cimarron* (wild balsam), or *bálsamo Colorado* (red balsam, Puerto Rico).

Other common names that allude to medical uses are *flor de baño* (bath flower, El Salvador), *herba de erisepala* (erysipelas herb, Guatemala), *hierba de cancer* (cancer [any sore] herb, Guatemala), *kunabiaya* (water-medicine in Kunana), *zorillo* (skunk, Costa Rica), and *zorillo real* (royal skunk, Costa Rica). The references to the skunk are probably because the plants resemble *Chiococca alba*, which is also called *zorillo*.

As with several of their names, the Maya have a distinctive viewpoint and say *k'anán* [*sax-canaan*, *canaan*, *ix-canan*, *kanan*, *neanan*, *ix-kanan*, *xcanal*, *xcanan*, *xkané*] (*ya'ax*, green, *k'anán*, necessary, Belize, Yucatan,) or *ix-canan amarillo* (yellow necessary, Guatemala). These people consider the plant "necessary" because it is important in religious ceremonies, and it is a traditional medicine for skin diseases. According to Arvigo and Balick (1993) *ix-canan* means "guardian of the forest," although no basis for that has been found except by allusion. The Maya also call it *chactoc* [*chadoco*, *chacloco*] (*chac*, red, *toc*, remove, Belize, Tamaulipas) because it "removes" the skin problems. In Belize, the plants are also *klaushpâm* (*klaush* does not seem to be in Maya, *pâm*, toucán, *Aulacorhynchus prasinus prasinus*, Maya) and *sac-le-much* (*sak*, white, *le'* leaf, *much*, frog, Maya).

Some names clearly allude to the edible fruits, including *recadito* (little gift, Columbia) and *uvero* (grape tree, Panama). The name *pata de pajaro* (bird foot, Puerto Rico) probably is an indication that the birds also have been seen eating the fruits.

Some names have obscure references. The allusions to the *canilla de venado* (deer's long bone, Nicaragua) and to a *canudo* [*canuto*] (tube, Guatemala) might be references to use in an indigenous musical instrument, because *Hamelia* is also called by the instrument's name *zambumbia* (El Salvador). The instrument is usually known as *zambomba*, and consists of a hollow tube, closed on one end by a skin, with a cane in the middle, and played by rubbing the cane with a moist hand. Maybe the reference to *canilla* and *canudo* means that *Hamelia* stems have been used for that "cane."

The meanings of some of the names are not readily apparent although we can translate them. What, for example, does *chichipin* [*chichipince*, *chichipû*] (to rain drop by drop, Náhuatl, Guatemala, Honduras, El Salvador) have to do with the plants? Other names that are not obvious in meaning are *cacauapaxtle* [*cacanapazue*] (chocolate moss, Náhuatl, Veracruz), *doncilla* (virgin, El Salvador), *estirrina* (little spoon, Nicaragua), *flor de cangrejo* (crab flower, Guatemala), *herva de rato* (mouse's herb), *hierba de Cuba* (Cuban

herb, Yucatán), *leoncito* (little lion, Colombia), *pañete* (little cloth, Veracruz), and *xuchit paltimatía* (*palta* is avocado, *Persea americana*, El Salvador). Maybe spoons are made of the stems to give *estirrina*, and the leaves do look a bit like those of *palta*. Does *cacahuaxochitl* (chocolate, flower, Náhuatl, Veracruz) refer to the red flowers?

Simple and untranslated names include [*palo de*] *masamora* (Nicaragua), *pili-tso* (Guatuso, Costa Rica), *pisí* (Costa Rica), *ponasí* [*bonasí*] (Cuba), *sibunkhen* (Kekchi, Yucatan), and *sisipinse* (Guatemala). Apparently, there is some relationship between the following names, but it is far from certain what the original may have been—*desyerba conuco* (remove weeds from a garden, Dominican Republic), *bencenuco* (maybe=*vence conuco*, or garden conqueror, Colombia), *cerva conuco* (deer garden, Dominican Republic), *buzunaco* [*buzunuco*] (Dominican Republic), and *buzunaco coral* (Cuba). If Spanish was not the original language, these all might have been derived from some Taino word resembling *buzunuco*.

Throughout its range, the fruits are utilized by people fresh from the plant or fermented into a drink (Standley 1920–1926). In addition, an antiscorbutic syrup is sometimes made from the fruits as a remedy for dysentery. The wood, which is light or dark brown and hard, has been used for various items.

However, the most common use seems to be for skin problems such as sores, rashes, burns, itching, cuts, fungus, and insect bites and stings. In Mexico, Belize, and the Caribbean, the crushed leaves are applied to cuts and bruises, and baths made with leaves and fruits are used for skin diseases (Standley 1920–1926, Roig 1945, Liogier 1974, Vásquez and Jácome 1997). Similar preparations are used for measles and rheumatism. Fruits and leaves are macerated to make a medicine used against sarcoptic mange. Leaves are used in vaginal washes and to treat migraine and other headaches.

The plants contain several bioactive chemicals, including ephedrine (Chaudhuri and Thakur 1991), flavanone glycoside (Aquino et al. 1990), and oxindolic alkaloids (Borges et al. 1977, 1979). Ethanol extracts in the laboratory act against *Staphylococcus aureus*, and water extracts combat *Escherichia coli*, *Salmonella typhosa*, *Sarcinia lutea*, *Serratia marcescens*, and *Shigella flexneri* (Jiménez et al. 1979b). Analgesic effects (Esposito-A. 1985) and antifungal activity against *Neurospora crassa* (López-A. et al. 1981) also have been shown. All of these extracts are astringent and antidiarrheal (Pérez et al. 1996).

Still, the best-known chemical in the plants is tannin. The high tannin content has also prompted people to use both leaves and stems in tanning leather (Standley 1920–1926, Liogier 1974). Many people just plant it as an ornamental because both fruits and flowers attract birds.

Only rarely did ruby-throated hummingbirds stop at my plants. Even when they did, they were rarely there more than a day or two. In their place, I was able to watch zebra longwing butterflies (*Heliconius charitonius*) all year long.

### *Hedeoma*

(Christiaan H. Persoon altered this name from *hedyosmon*, an ancient name of mint, from the Greek *hedys*, sweet, and *osme*, scent)

*Hedeoma hispídum* (with short stiff hairs)

*maka chiaka* (*maka*, probably skunk, but also meaning ground, Dakota)

[mock, rough] pennyroyal (“pennyroyal” where “royal” is sometimes rendered *ryal* or *rial*, derived from Anglo-French *pulyole ryale*, and from Latin *pulegiol*, little thyme, plus *real*, royal; originally applied to European *Menthapulegium*); rough false-pennyroyal [rough falsepennyroyal] *pe-zhe-tu-hu* (*pe*’-zhe, herb, *to*’-ho, green, Osage for *H. pulegioides*)

rough hedeoma (a translation of the scientific name)

*su*’wa *ki*’ *wi*’*ti*’ (smell-root, Catawba; perhaps for *H. pulegioides*)

Frederick Pursh introduced *H. hispidum* in his *Flora Americana Septentrionalis* (Flora of North America) of 1814. That was only 8 years after Persoon (1761–1836) created the genus. This endemic American genus contains 38 species, ranging from the southern United States into South America (Mabberley 1997).

*Hedeoma hispidum* is one of the least-used members of the genus according to Moerman (1998). The Dakota used the leaves to treat colds and add flavor to food to make it more appealing particularly to those who were sick (Gilmore 1919).

The species most used in the eastern United States, *H. pulegioides*, was included in the pharmacopoeia of the Catawba, Cherokee, Chickasaw, Delaware, Iroquois, Mohegan, Nanticoke, Osage, Ojibwa, Rappahannock, and Shinnecock (Moerman 1998). Since the Chickasaw used a cold infusion of the roots for itching eyes (Taylor 1940), they and their relatives may have used *H. hispidum*.

Most, if not all, members of *Hedeoma* contain a variety of essential oils that provide the fragrance, particularly pulegone (Lawless 1995). These oils can be lethal if ingested (Millsbaugh 1982, Foster and Duke 1990).

### *Helenium*

(The Greek name of some plant, said by Linnaeus to be named after Helena or Helen of Troy, wife of King Menelaus of Sparta)

***Helenium autumnale*.** a. Upper part of plant showing habit, b. Lower stem and roots. From Buchholtz 1968.

***Helenium amarum*** (bitter)

bitter-weed [bitterweed]

*pahí hó:mi* (*pahí*, grass, *hó:mi*, bitter, Koasati)

sneeze-weed [sneezeweed]

*Sonnenbraut* (sun bride, German)

Spanish daisy

yellow-dicks [yellowdicks]

***Helenium autumnale*** (flowering in the fall)

autumn [common] sneeze-weed [sneezeweed]

*cabezona* (big head, Valley of Mexico)

*cacamosiksan* (it makes you sneeze, Cree)

*chapuz* (Michoacán)

fever-grass

*Herbst-Sonnenbraut* (autumn sun bride, German)

*manzanilla* (chamomile, Mexico); *manzanilla de Yucatán* (Yucatan chamomile, Mexico)

ox-eye

*plumajillo* (little feather, New Mexico)

staggywort (from the symptoms of cattle after grazing on the plants)

[false, swamp] sunflower

*tcatcamo'sikani* (inhalant, Meskwaki)

yellow dog-fennel  
yellow-star

According to Mish (1988), the first recorded use of the common name “sneezeweed” was in 1837, when it was used for *Helenium autumnale*. That may well be true, but sneezing had been associated with plant names for far longer. At least as long ago as Leonard Fuchs’s *Herbal* of 1542, a European composite was called “sneezewoort.” That plant was also called *Ptarmica* (Greek, to cause sneezing), and is now *Achillea ptarmica* (Linnaeus [1753] 1957, Brako et al. 1995). Thus, knowing that plants caused sneezing is much older than the 16th century. One might say that “sneezeweed” dates at least to Galen, who lived between A.D. 129 and 200. He wrote, “The flowers of *Ptarmica* have the property of causing sneezing” (Galen in Meyer et al. 1999).

Today most cultures treat sneezing casually. However, sneezing was not always considered a trivial event (Panati 1987). In the 4th century B.C., both Aristotle (372–287) and Hippocrates explained sneezing as the body’s attempt to expel some foreign substance. They further observed that sneezing associated with particular illnesses sometimes foretold death. It became a popular custom to offer benedictions such as “Long may you live!” or “May you enjoy good health!”

About 100 years later, the Romans held that sneezing was the body’s attempt to expel a sinister spirit that would later cause illness. To suppress a sneeze was to court illness or even death. Therefore, the custom became one of offering “Congratulations!” when someone sneezed.

The Christian expression “God bless you!” was actually a papal fiat in the 6th century A.D. That was a time of a plague in Italy with one of the foreboding symptoms being severe sneezing. People often died shortly after beginning the sneezing bouts. Pope Gregory the Great asked the healthy to pray for the sick. He also asked that the current phrase of “May you enjoy good health!” be replaced and suggested the invocation “God bless you!” If no one was around to offer the blessing, the sneezer was advised to say “God bless me!”

Today, we have the residual of those 6th century events in multiple languages, and religions other than Catholicism. When someone sneezes, we say:

*Gesundheit!* (German)

*Felicità!* (Italian)

*Salud!* (Spanish)

One of the many useless bits of information that I still remember from high school Spanish classes was the following bit of doggerel. If someone sneezed and no one offered *Salud!*, we were to say—*Qué dios me bendiga hast a llegue a donde hay a gente!* (May bless me until I get where there might be some people!). It did not make sense at the time, but in historical context, it fits perfectly.

At least some indigenous Americans had their own version of the association between sneezing and maladies. The Cherokee used dry, powdered *Helenium* leaves to induce sneezing (Hamel and Chiltoskey 1975). The Menomini made a powder of flowers to cause a person to sneeze, and thus eliminate a headache and relieve a cold (Moerman

1998). The Meskwaki also inhaled the powder of the dried florets to relieve colds and catarrh (King 1984).

The Cherokees prescribed an infusion of the roots of *H. autumnale* to prevent menstruation after childbirth (Hamel and Chiltoskey 1975). The Comanches made an infusion of stems as a wash to lower fever. The Menomini also used the plant as an alterative (Moerman 1998).

The only records of Muskogean people using *Helenium* seem to be the Koasati. They used *H. amarum* in a sweat bath to reduce swelling, particularly that associated with dropsy (Taylor 1940).

Helénalin, a lactone apparently associated with sesquiterpenes, is known from all species of *Helenium* (Foster and Duke 1990, Hocking 1997). Helénalin kills fishes, worms, and insects (Foster and Duke 1990). The plants are poisonous to cattle and may cause contact dermatitis in some people. Both species are used identically in South Carolina, where people make a tea to reduce fever (Morton 1974). Morton (1974) records tenulin, a pseudoguaianolide, as the fever-lowering compound that is also responsible for poisoning grazing animals. However, Lewis and Elvin-Lewis (1977) attribute the poisoning of cattle to the glycoside dugaldin. Also present are aromaticin and amaralin (Morton 1974). Hocking (1997) lists the bitter glycosides tenulin and isotenulin in *H. amarum*.

Although what we now call *Helenium* was unknown to the classical Greeks, an association of Helen of Troy's name with healing plants by Linnaeus was appropriate (Baumann 1993). Helen gave a painsoothing drink *nepenthes* to Telemachus and his companions to make them forget their warriors fallen in battle. Furthermore, a plant named *helenion* or *helenium* by the ancients was thought to have sprung from Helena's tears on the death of the seafarer Canapos who had taken her and Menelaus to Egypt after the fall of Troy. No one is sure what the ancients were calling *helenion*, but now a group of American plants commemorates this Greek heroine.

### *Helianthus*

(Linnaeus used the Greek *helios*, the sun, and *anthos*, a flower)

***Helianthus annuus***, a. Habit, b. Ray flower, c. Disk flower, d. Achenes, two views. Drawn by Regina O. Hughes. From Reed 1971.

***Helianthus annuus*** (annual)

*añil* (blue, from use of seeds as dye, New Mexico)

*auti cákhire* (Catawba)

*castill* (probably through the mistaken idea that they were from Spain, La Bajada, New Mexico, Curtin 1947)

*chimal-acatl* [*chimalati*] (*chimalli*, shield, *acatl*, cane, Náhuatl, Mexico)

*florde sol* (sun flower, Mexico); *flùr-na-greine* (*flùr* flower, *na*, of the, *greine*, sun, Gaelic); *plùr-na-greine* (*plùr*, flower, *na*, of the *greine*, sun, Gaelic)

*gigantón* (big one, Mexico)

*girasol* (turns with the sun, Italian, Mexican Spanish); *mirasol* (looks at the sun, Spanish)

*haash abé* (*haash*, sun, *abé*, image, Mikasuki); *hvsevháke* (*hvse*, sun, *vháke*, image, Muskogee); *hashi* or *hashi napakali* (*hashi*, sun, *npakali*, flower, Choctaw); *hashi' pakali'* (*hashi'* sun, *pakali'*, flower, Chickasaw); *hvse hecv* (*hvse*, sun, *hecv*, literally "having sight," but surely meaning "seeing," Muskogee)

*hivai* (Akimel O'odham or Pima, Arizona)

*ho-soñ-a* (looking at you, Kiowa)

*i la akiktce'hi* (*i'la*, sun, *akiktce'hi*, flower, Ofo)

*kirik-tara-kata* (*kirik*, eyes, *tarn*, having, *kata*, yellow, Pawnee)

*lampote* (big lamp, Mexico)

*maíz de tejas* [*teja*, Texas] (literally Texas or “tile” corn, but also possibly based on the word *natasi* or *yatasi*, the name one tribe of Caddo called themselves, Mexico)

*mapi'-i-ti'a* (*mapi'*, sunflower, *i'ti'a*, big, Hidatsa)

*mi-to-o-xthe* (always looks to the sun; *mi'*, sun, *ta*, in that direction, Osage)

*quisnaniquitonale* (*ixneneulia*, resembling, *quiltil*, greens, *tonilli*, cooked, Náhuatl, Guerrero)

*soleil* (little sun, Quebec); *tourne soleil* (turn with the sun, Quebec)

*Sonnenblume* (sunflower, German)

sunflower [*sonne flower*] (first used as a translation of *flossolis*, originally applied to *Heliotro* the 1560s. Probably first applied to *Helianthus* by John Gerarde in 1597 as “*Flos solis maior*. The greater Sunne flower.” However, the first record of the sunflower in Europe was a drawing by Rembert Dodoens in 1568. Then Harriot called it *Planta Solis* in [1590] 1972.)

*te'xlk lak* (*te'xlk*, flower, *la'k*, sun, Atakapa)

*wahcha-zizi* (*wahcha*, flower, *zizi*, yellow, Dakota); *zha-zi* (*zha*, herb, *zi*, yellow, Omaha-Ponca)

*xaricarmata* (Tarascan, Michoacán)

*yendri* (Otomí, Hidalgo)

***Helianthus occidentalis*** (western)

fewleaf sunflower

***Helianthus strumosus*** (scrofulous, from the thickbased hairs)

pale-leaf woodland sunflower [paleleaf woodland sunflower]

For decades, we have believed that the sunflower (*Helianthus annuus*) was domesticated in North America. That view was largely the result of Charles Heiser's research into the genus (cf. Heiser 1951, 1976). Now, a seed taken from an archaeological site in Central America has shaken that idea by predating all North American sites (Lentz et al. 2001). Heiser is resisting the new interpretation (cf. Heiser 2001, Lentz 2001a,b).

Regardless, when Europeans arrived, sunflowers had been cultivated in western North America since about 4200 B.P. (Fritz 2000b). Historic southeasterners were largely continuing the cultivation of the plants of the old Eastern Agricultural Complex, including sunflowers (Hudson 1976, Yarnell 1986, Smith 1992), which is often dated as beginning in the early second millennium B.C. In addition, Hudson (1976) writes, “And considering the importance of the sun in their belief system, the Southeastern Indians would not have failed to notice that the sunflower turns to face the sun when it rises, and then follows it across the heavens to where it sets in the west.”

Just when the sunflower was introduced to Europe is not known, but it was there within the first decade of Columbus's arrival in the New World (Reveal 1992). Both Heiser (1976) and Hawkes (1998) agree that the first published record of the species in

Europe was with Rembert Dodoens in 1568. However, Hawkes (1998) points out that by that date the species was widely cultivated in Europe.

The record in the east is patchy regarding who cultivated sunflowers and who did not. Harriot ([1590] 1972) saw them being cultivated among the Carolina Algonquians in the 1580s. Harriot wrote of sunflowers in 1588 when he said: "There is also another great hearbe in the forme of a Marigolde, about sixe foote in height; the head with the floure is a spanne in breadth. Some take it to bee *Planta Solis*: of the seedes heereof they make both a kinde of bread and broth" (Harriot [1590] 1972). Champlain found them grown near Lake Simcoe, Ontario, in 1615, where, in addition to maize, the Huron "plant likewise squashes, and sunflowers, from the seeds of which they make oil, with which they annoint the head" (Champlain in Gilmore 1919).

Bernard Romans ([1775] 1961) found the Choctaw mixing sunflower meal with maize. He wrote, "They cultivate...the *Helianthus giganteus* [*H. annuus*]; with the seed of the last made into flour and mixed with flour of the *Zea* they make a very palatable bread." Although no records of the other southeastern people have been found growing and eating sunflowers, Muskogean are famous for mixing various seeds in their bread flour (see *Carya*, *Castanea*, *Fagus*, *Quercus*). Moreover, the foods of most of the Muskogean people were similarly made (Hudson 1976). Oddly, sunflowers were not mentioned by Bartram ([1791] 1958), nor does Moerman (1998) list a single eastern tribe as using them as food. For more information on indigenous use, see Heiser (1951).

Gilmore (1919) did not find sunflowers cultivated among the Dakota, Omaha, Pawnee, or Ponca. He did not find the Arikara, Mandan, and Hidatsa [Gros Ventre, Minitari] growing them, but they did. There is a long, instructive quote in Heiser (1976) on Hidatsa use of the sunflower. Indeed, the Hidatsa called the month of April *mapi-o'ce-mi'di* (sunflower planting moon); see also Waheenee et al. (1987).

Medicinal use of *H. annuus* is entirely among the western tribes in Moerman (1998). The Ojibwa, however, used *H. occidentalis* as a poultice to help bruises and contusions heal. The Iroquois used *H. strumosus* roots to worm their children (Moerman 1998), and the Meskwaki used the plant to treat lung troubles (King 1984). Roots of *H. strumosus* are edible and are now recommended as food for people with diabetes (Hocking 1997).

### *Heliopsis*

(From Greek *helios*, the sun, and *opsis*, resembling, referring to the flowers)

***Heliopsis helianthoides*.** From Britton and Brown 1898.

***Heliopsis helianthoides*** (resembling *Helianthus*, which see)  
 [smooth] ox-eye [oxeye]  
*gi'ziso 'bûgons'* (small sun leaf, Ojibwa)  
 sunflower heliopsis (a book name)

In an unusual move, Linnaeus ([1753] 1957) gave the same species four names—*Buphthalmum helianthoides*, *Silphium helianthoides*, *Silphium solidaginoides*, and *Rudbeckia oppositifolia* (Reveal 1983). When Linnaeus made mistakes, he did it right. It was not until 1807 that the species was put in *Heliopsis*.

Described as a “bizarre individual and brilliant mycologist, born in South Africa, studied in Germany, lived in Paris,” Christiaan H. Persoon created *Heliopsis* in *Synopsis Plantarum* in 1807 (Correll and Johnston 1970). That is now a genus of 15 upland herbs endemic to the Americas (Mabberley 1997). *Heliopsis helianthoides* occurs over much of southern Canada and eastern United States west to the Dakotas, Nebraska, Colorado, and New Mexico (Correll and Johnston 1970). Nearby to the south is *H. parvifolia*, growing in the Trans-Pecos area of Texas, New Mexico, Arizona, and south to Durango, Nuevo León, and Tamaulipas. Also in Mexico is *H. longipes*, which grows in Guanajuato, Querétaro, and San Luis Potosí (Martínez 1967).

Records have been found for only two tribes using *H. helianthoides*. The Ojibwa made a root decoction or chewed fresh roots and applied them to stimulate limbs (Densmore 1928). The Meskwaki made a medicine of the root for lung problems (King 1984).

In Mexico, *H. longipes* is called *chilcuan*, *chilcuague*, *peritre* [*pelitre*], or *peritre del país* (country *peritre*). The first two names are derived from Náhuatl *chili*, chile or *Capsicum*, and *mecatl*, thread, referring to the filiform roots that have a spicy taste (Martínez 1969). These plants were first noted by Francisco Hernández (1651) when he wrote about the “*Chilmecatl* seu *Ychcha*” The uses Hernández gave were virtually the same as those found by Martínez (1969).

The bark of the roots, when chewed, is spicy, numbs the tongue, and induces abundant saliva. The plant is added to beans as a condiment in place of chiles, or to alcoholic

drinks to give them a special flavor. Roots are also chewed to relieve toothache. Alcoholic extracts have been used as a stimulant and as an anesthetic.

Root of *H. helianthoides* contains scabrin (butyl amide of an 18-carbon unsaturated fatty acid) and heliopsin (Hocking 1997). Scabrin is considered a promising source of insecticide (Mabberley 1997). *Heliopsis longipes* contains *N*-isobutyl-2,6,8-decatrienamide and scabrin. Both have been used as insecticides, especially to get rid of house flies (Hocking 1997).

### *Heliotropium*

(From *heliotropion*, Greek *helios*, the sun, *trepo*, turning; ancient writers believed that the plant turned toward the sun in flowering)

***Heliotropium.*** *Heliotropium curassavicum* , a. Flowering and fruiting branch, b. Apical section of inflorescence, c. Flower, from above, d. Flower, longitudinally dissected, e. Stigma, f. Floral diagram, g. Fruit. Drawn by Priscilla Fawcett. From Correll and Correll 1982. *Heliotropium polyphyllum* . Drawn by P.N.Honychurch.

***Heliotropium europaeum*** (the Old World species known to settlers)

*eliotropio* (from Greek *heliotropion*, Italian); *héliotrope* (French); *heliotrope* (in English by about A.D. 1000); *heliotropio* (Spanish)

*erba porraia* (warty herb, Italian); *hierba verruguera* (warty herb, Spanish); *verrucaria* (warty herb, Portuguese)

*Sonnenwende* (turns with the sun, German)

*tornassol* (turns with the sun, Portuguese)

***Heliotropium curassavicum*** (from the island of Curaçao)

*absinthe bord de mer* (seaside absinthe or *Artemisia absinthium*, a completely different kind of plant in the Asteraceae, Guadeloupe, Martinique)

*alacránillo [de play a]* (little [beach] scorpion, Cuba, Hispaniola); *hierba del alacrán [yerba de alacrán]* (scorpion herb, Dominican Republic); *cola de alacrán* (scorpion tail, Veracruz); *rabo de alacran de playa* (beach scorpion tail, Cuba)

*ba:bad 'i:wagi* (*ba:bad*, toad/frog, *'i:wagi*, eaten greens, Tohono O'odham, Arizona, Sonora); *cama de sapo* (toad's bed); *hierba del sapo* (toad herb, Sonora, Nayarit)

Chinese-pusley (Texas, Arizona)

*cola de mico* (monkey tail, Texas, Veracruz); *rabo de mico* (monkey tail, Yucatan)

*cotorrera de playa* (beach parrot, Puerto Rico)

*cresta de galo* (rooster comb, Brazil)

*hant otópl* (what the land sticks to, Seri, Sonora)

*heliotropio cimarrón* (wild heliotrope, Colombia); [alkali, salt, seaside, wild] *heliotrope* (Sonora, Arizona, Texas, Bahamas, Puerto Rico)

*hierba del torojo* (Sonora)

*hierba del vidrio* (glass herb); *pasto vidrio* (glass grass)

*hoskos [hoshos]* (Cahuilla of California)

*jaboncillo* (little soap)

*kaakaichu sisivoda* (quail's topknot, Akimel O'odham, Arizona, Sonora)

*kakachu e'e s [kaakaichu e'es]* (quail's plant, Akimel O'odham, Arizona, Sonora); *kakaichu 'i:wagi* (*kakaichu*, Gambel's quail, *Callipepla gambelii*, *'i:wagi*, eaten greens, Tohono O'odham, Arizona, Sonora)

*kokolode shimaron [cocolode]* (wild *kokolode*, Netherland Antilles)

[sea, small seaside, wild] *lavender* ("sea lavender" is a name usually reserved for *Argusia gnaphaloides*, in the same family, Barbados)

*pata de gallo* (chicken foot)

pond weed (Bahamas)

*potács camoz* ("what thinks it is an iodine bush," *Allenrolfea*, Seri, Sonora)

quail-plant [quailplant] (maybe quail eat the seeds, Texas)

*quinaquina bord de mer* (seaside quinine, Guadeloupe, Martinique)

*romarin blanc* (white rosemary, Guadeloupe, Martinique)

*rosa morada* (purple rose, Nayarit)

sailor's tea

*verveine bord de mer* (seaside verbena, Guadeloupe, Martinique)

***Heliotropium polyphyllum*** (many leaves)

[pineland, yellow] heliotrope (Florida, Bahamas)

*Heliotropium curassavicum* was described by Linnaeus ([1753] 1957). Before him, the plants had been discussed by European authors starting with Robert Morrison's list of plants cultivated in London in 1669. Although the species is native to the Americas, it had become naturalized in France by the time Thomas François Dalibard (1703–1779) published his *Flora Parisiensis* in 1749. Paul Hermann had the species in cultivation in Holland in 1687. All the pre-Linnaean writers called the plants *Heliotropium*, following the classical usage for *H. europaeum*.

In its native range of seacoasts and borders of other saline areas from Delaware to Florida, west to the western states, the Caribbean, Mexico, Central and South America, *H. curassavicum* has a history of use by many different people. Perhaps because other species are more potent, there are few records of use in the Caribbean. There a decoction is used to treat leukorrhea in Curaçao, and Cubans use it as a substitute for *H. indicum* (Morton 1981).

There are more records of people using *H. curassavicum* in the western United States than elsewhere in North America. Perhaps records of it are abundant because there are relatively few other species found in the western United States.

Although Curtin (1949) did not note use of *Heliotropium* among the Pima, it was mentioned earlier by a study by Frank Russel in 1908. At that time, "The upper part of the light yellowish root is dried and ground in mortars, dried again, and ground very fine upon a metate, when it is ready to be applied to sores or wounds after they have been washed" (Rea 1997). In his recent study, Rea (1997) found only that the modern Pima use the roots in a tea for sore eyes.

The Paiutes and Shoshone made a medicine to treat diarrhea from *H. curassavicum*, and a decoction served as a diuretic, emetic, and gargle for sore throat (Moerman 1998). The Shoshone of the Great Basin also used a decoction of the plant tops to bring out measles (Moerman 1998). The Tubatulabal of California took a decoction of the entire plant to relieve dysentery, and ate the seeds (Ebeling 1986). The Cahuilla formerly used it and had a name for it, but the informant could no longer remember what it was used for (Ebeling 1986).

*Heliotropium curassavicum* is used in Nayarit to help control coughs (Martínez 1969), and in Veracruz to treat asthma, fever, anemia, and scorpion stings (Vásquez and Jácome 1997). People use the plants as food and medicine in Belize (Balick et al. 2000). *Cresta de galo* is considered a depurative in Brazil (Hocking 1997).

Indians (unspecified) made a purple dye from *H. curassavicum* (Hocking 1997). The flowers of *H. polyphyllum* were used to make a yellow dye (Hocking 1997).

Like *H. angiospermum*, there are pyrrolizidine alkaloids in *H. curassavicum* (Mors et al. 2000). These chemicals are known to be liver toxic and cause venoocclusive disease of the liver (Smith and Culvenor 1981, Foster and Hobbs 2002).

*Heliotropium*: Scorpion-Tail

(Greek *heliotropion*, from *helios*, the sun, *trepo*, turning)

Along the margins of hammock forests in southern Florida you are likely to see a small herb about 0.6 m (2 feet) tall with a flower stalk curved around like a scorpion's tail. That comparison is exactly what some people make when they see it, and the common name scorpion-tail (Florida, Puerto Rico) has been used for many years. Indeed, throughout its range, people have associated scorpions with *Heliotropium*. In southern Florida, *H. angiospermum* is the most common species. Since scorpions were once common where the plants grow in Florida, the name makes sense. These stinging animals were so common in the past that they prompted a comment from Jonathan Dickinson, who was forced to lie among them in a Jaega hut in 1699 (Andrews and Andrews 1945).

Other names that associate the plants with scorpions include *alacrán* (scorpion), *alacrán chico* (little scorpion), *alacrancillo* (little scorpion, Cuba, Hispaniola, Veracruz), *cola de alacrán* (scorpion tail, Veracruz), *flor de alacrán* (scorpion flower, Guatemala, Belize), and *rabo de alacrán* (scorpion tail, Cuba, Puerto Rico, Dominican Republic), or scorpion tail (Belize). Obviously, in different places, people associate the plant with different species, but in Florida the scorpion most likely to be found with the herb is *Centruroides gracilis*. This scorpion is known as the Florida bark scorpion, the brown bark scorpion, or the slender brown scorpion. In Cuba, this animal is known as *alacrán prieto* (black scorpion) or *alacrán azul* (blue scorpion). Of course, there are other role models for the plants elsewhere, but this is a widespread animal.

This allusion to the animal must be a tropical view, especially since the plants were put in the genus *Heliotropium* by Linnaeus and many of his predecessors. The name *Heliotropium* goes back to the classical Greeks, with ancient writers believing that the plant turned toward the sun while flowering. The name has even been rendered "turnsole" in English (from 1300s, based on Latin *tornare*, to turn, and *sole*, sun).

In Florida, the Seminoles say *ho:malastocî* (*home*, bitter, *lasetv*, taste, *oce*, small, Creek) or *hō:mó:cî* (small bitter, Mikasuki). They usually black pepper (*Piper nigrum*) by that name, but sometimes they distinguish between the two with the modifier *-a:bi* (replica or resembling) for the *Heliotropium*. Although it has a name, Sturtevant's (1955) informants claimed it was not used. A similar comparison to a "pepper" is made by the Maya who say *nemax* [*nemaax*, *remax*] (*ne*, tail, *maax*, wild chile, Yucatan). That name is given because the inflorescences resemble the pedicel of the chile, *Capsicum*.

Others are impressed by the curved inflorescence, but compare it to other things. Some think of other tails, and say it is a *cola de mico* (monkey tail), dog's tail, or *rabo de mico* [*rabamàco*, *rabomico*, *rabo mico*] (monkey tail, Yucatan, Nicaragua). Others think it looks like their chickens and say *crête de coq* (rooster's comb) or rooster comb (Bahamas, Virgin Islands). Some think it resembles musical instruments, particularly the *cabeza de violin* (violin head or crozier, Sonora).

Some of the names either refer to the inflorescence or pubescence, and their application is not clear. Since these plants are normally glabrous, perhaps the names originally referred to related species. The names are cat tongue (Bahamas, Virgin Islands), *pitone velue* (shaggy ring), and *veloutte* (velvety).

Several of the names make allusions that are lost to those outside their region of use. One of these is *cotorrerilla* (little parrot, Puerto Rico), probably meaning that birds eat

the flowers and/or fruits. Maybe *creéré cacao* (Haiti) means that the plant grows with cacao (*Theobroma cacao*). What horse bush, *mocos de pavo* (turkey snout [mucus], Dominican Republic) and *montjoli* (pretty mount, Haiti) allude to is uncertain. There is a hotel called *Mont Joli* in CapHaitien referring to a nearby mountain, but I would not be surprised if the plant name referred to a female body part.

Translations are not available for some names. These include *cocolode* [*kokolode*] (Bahamas, Curaçao, Virgin Islands), *laven co'va* (Mayo, Sonora), *soguilla* (Sonora), and *zimbaclot* (Haiti).

A number of names have medicinal references. Among these are *herbe à chiques* (tobacco herb, Haiti), *herbe à clous* [*z'herbe à clous*] (boil herb, Haiti), *herbe à malingres* (herb for the sickly, Haiti), and sorebush. There are also comparisons within the same family, as in *borraja* (borage, *Borago officinalis*) another noted European medicinal herb.

Although there are few direct records of *H. angiospermum* having been used as a remedy for eye problems, the common names suggest that it has. Indeed, Ayensu (1981) and Morton (1981) record that in Jamaica and the Caicos islands the plant is boiled and the decoction used to treat eyes that burn.

One name given that records the use as eye medicine is eyebright (Bahamas, Virgin Islands). The name "eyebright" in Europe is usually given to *Euphrasia officinalis* and its relatives. The first record found of that name being used was 1533 when Sir Thomas Elyot wrote his list of "thynges good for the eyes: Eyebryght..." in his medical book, *The Castel of Helthe*. That plant had the reputation in Europe for being a cure for weak eyes between 400 and 500 years ago. A variant of "eyebright" used in the Bahamas and the Virgin Islands is "sunlight".

Along the same line, *H. angiospermum* has been considered a variant of clary (*salvia sclarea*, Lamiaceae) with vernacular names including small wild clary, white clary, and wild clary. Since about A.D. 1000 variants of the word "clary" have existed and this aromatic mint of southern Europe was used to adulterate wines, as a condiment, and as a medicinal herb. In the 1500s, the name also was transformed into clear-eye, Godes-cie, and see-bright to emphasize its use for treating the eyes.

Although it is used for the eyes, primary among the recorded uses for *H. angiospermum* is as a remedy for skin problems. In Cuba, scorpion-tail is used on buns. People take the dried leaves, make them into a powder, wet the burned spot, and shake on the powder (Roig 1945).

Hispaniolans use the leaves in decoctions to wash sores and for general cleaning of the baby's skin at birth, or for peeling baby skin (Liogier 1974, Ayensu 1981). A decoction also is taken internally to cure skin sores, and the pounded leaves are mixed with petroleum jelly and applied to boils. Boiled plants are used to treat headaches, boils, fresh cuts, and wounds. Mexicans consider the plant a remedy for nosebleed, gum disease, dysentery, flu, and skin problems (Standley 1920–1926, Vásquez and Jácome 1997). A decoction is used as a bath to treat lightheadedness, jaundice, and rheumatism (Liogier 1974).

The few studies that have been made of this species of scorpion-tail record that *H. angiospermum* contains arginine, amino alcohols, pyrrolizidine alkaloids, and ornithine decarboxylase (Birecka et al. 1985, 1987). In general, the pyrrolizidine alkaloids are potent poisons, and children have been killed by overdoses of the plant decoction in

Barbados (Morton 1981). The pyrrolizidine alkaloids are notorious in the genus and family (Dattagupta and Datta 1977, Mohanraj and Subramanian 1978, Birecka et al. 1980, Davicino et al. 1988, Asibal et al. 1989, Roeder et al. 1991, Constantinidis et al. 1993, Trigo et al. 1993, Farsam et al. 2000). Other studies suggest that some species have antitumor principles (Kugelman et al. 1976), insecticidal and antifungal properties (Villarroel et al. 2001), and wound-healing effects (Reddy et al. 2002).

Several other species in the genus are used in a similar way as medicines. In the Caribbean, the best known and most widespread is *H. curassavicum*. That species ranges from Delaware, south through Florida, the Bahamas, and the West Indies, and from Oregon south through Mexico and Central America, and in South America to Chile and Paraguay. *Heliotropium curassavicum* not only shares several common names with *H. angiospermum*, but both have essentially identical uses.

Probably even better known is *H. indicum*, as it was also in the Old World before Columbus's voyages. This species is the most widely used of all. It is known in Ayurvedic medicine by the Sanskrit names *hatisunadā*, *srihastini*, and *bhūrūndi*. This species has been carried around the world for its medical applications.

Insects applied the chemicals in these plants long before humans. Both moths and butterflies sequester the pyrrolizidine alkaloids. Moreover, like humans, they have different uses for the chemicals. Larvae of the arctiid moth *Hyalurga syma* store the poisons in a predator-defense system (Trigo et al. 1993). The Danaid butterflies (the monarchs, *Danaus plexippus*, and relatives) must use them to narcotize females before copulation can occur (Pliske and Saltpeter 1971, Edgar et al. 1974, Amladi 1975, Pliske 1975). Humans are relative newcomers in the chemical usage game.

### *Hepatica*

(Feminine form of *hepaticus*, pertaining to the liver, referring to the color and shape of the leaves, and to their curative properties)

***Hepatica nobilis*.** From Britton and Brown 1897.

*blåveis* (*blå*, blue, *vei*, road, Norwegian)

*dithean Abraoin* (*dithean*, daisy, *Abraoin*, April, Gaelic)

*Edellebere* (noble berry, German)

*erba trinita* (Italian); herb trinity; *Herba Trinitalis* (Sir T. Browne wrote in 1646 that the plant “obtaineth that name onely from the figure of its leaves, and is one kind of liverworte or Hepatica”); *trinitaire* (of the Trinity, Quebec)

*hepatikos* (Greek); *hepar* (liver, Latin); hepatica (recorded in English in 1578 in the translation of Rembert Dodoens’s *Cruydeboek* of 1554 where he wrote, “The leaves of *Hepatica* are broad, and diuided into three parts”); *hepatique* (French); *hierba del higado* (liver herb, Spanish)

*Leberblumchen* (little liver flower, German)

liver-leaf [liverleaf] (dating from 1851)

liverwort [liver-weed] (plant for the liver; “liverwort” first used in English about A.D. 1100; perhaps originally applied to *Marchantia*, but later including *Hepatica*)

trefoil (a name now usually given to *Desmodium*, Fabaceae); *trifoglio epatico* (three-lobed liver, Italian)

*wapukwunes* (Plains Cree)

***Hepatica nobilis*** (well-known) (= *Anemone americana*, *H. acutiloba*, *H. americana*, *H. hepatica*, *H. triloba*)

*asawusk* (yellow weed, Potawatomi)

blue anemone; noble agrimonia (1578 translation of Dodoens’s *Cruydeboek* of 1554)

kidney-wort

[common] liverwort; noble liver-wort [noble liverwort, noble lyverwurte] (in English in 1578 translation of Dodoens’s *Cruydeboek* of 1554; “liver-wort” akin to *Leberkraut* in German and *leverkruid* in Dutch); round-lobed liver-leaf [roundlobed liverleaf]; three leafe lyverwurte (1578 translation of Dodoens’s *Cruydeboek* of 1554)

squirrel-cups

The history of these herbs dates from the classical Greeks and Romans. *Hepatica* is a classic example of the Doctrine of Signatures; people believed it would cure problems of the liver. Problems treated included cowardice, freckles, and indigestion (Dobelis 1986). Herbalists knew and recommended the plant. Dodoens (1578 translation) wrote, “The Hepatica or Noble Lyverwurte is a soveraigne medicine against the heate...of the Lyver.” Culpeper (1653) added, “It is a singular good herb for all diseases of the liver, both to cool and cleanse it, and helps inflammations in any part, and the yellow jaundice...a good remedy to stay the spreading of tetters, ringworm, and other fretting and running sores and scabs.”

When the Europeans arrived in the New World, they found these woodland herbs growing from northern Florida into Canada. Although botanists have divided them into at least four species over the centuries, the tendency today is to recognize them as varieties of a single Circumboreal species.

Several of the eastern tribes used the herbs for liver ailments, digestive upsets, laxatives, and to wash external injuries. The Cherokee made an infusion as an emetic for abdominal pains, as a laxative, for the liver, and made a compound medicine rubbed on swollen breasts and drunk for indigestion (Taylor 1940, Hamel and Chiltoskey 1975).

The Iroquois used *Hepatica* during childbirth, to prevent conception, to treat diarrhea and stiff muscles, and for shortness of breath in runners. Roots were chewed (by women?) to bewitch men, and used to tell fortunes (Moerman 1998). The Menomini used liverwort to treat female problems, especially leukorrhea, and dysentery (Smith 1923). The Meskwaki used an infusion to treat eyes and mouth problems (King 1984). The Nanticoke chewed petals to prevent summer fevers (Moerman 1998). The Ojibwa made a medicine of the roots as an abortifacient, to stop convulsions in children, and for liver ailments, and they made a poultice for bruises and inflammations. The Potawatomi took an infusion of root and leaves to cure vertigo (Smith 1933).

Use of these herbs had boom and bust years through the 1800s. In 1830, there was a great demand for potions containing the plants during the flu epidemic in New York (Hocking 1997). Then, during the Civil War, Porcher (1863) wrote: "A tonic and astringent, supposed by some to possess deobstruent virtues. It has been used to a considerable extent in haemoptysis and chronic cough; but Wood says it has fallen into neglect." Then, there was a "liver tonic" boom that consumed 450,000 pounds of leaves in 1883 alone (Foster and Duke 1990). But, by the time Millspaugh (1892) wrote his book *American Medicinal Plants*, he said, "It is now falling into disuse on account of its mild properties, forming as it does simply a slightly astringent, mucilaginous infusion." During its periods of popularity, it was collected for the drug market and sold as *Folia Hepatica*.

During its years of popularity, the primary use was as a mild mucilaginous astringent, to treat coughs, fevers, and liver ailments (Meyer and Meyer 1986, Foster and Duke 1990). Duke et al. (2002) do not even mention the plant; however, Foster and Duke (1990) considered it mildly astringent, demulcent, and diuretic. A leaf tea was used as the diuretic. Those of us old enough remember an old patent medicine called *Sal Hepatica* [liver salt] were misled. That laxative had only borrowed the plant's name (Ward 1999).

Hocking (1997) noted that *Hepatica* contains tannins, mucilage, and the glycoside hepatrilobin. He also found that the plants had been used to treat bronchitis, phthisis (tuberculosis), and influenza.

A single reference has been found to using the herbs as a dye source. The Potawatomi used roots to make a dye for mats and baskets (Smith 1933).

### ***Heterotheca***

(From Greek *heteros*, different, and *theca*, case, alluding to the dissimilar ray and disk achenes)

***Heterotheca subaxillaris*.** From Britton and Brown 1898.

***Heterotheca subaxillaris*** (having flower clusters near the axil where the leaves join the stem)

*árnica* (name used by Kikapoo displaced to Coahuila, Mexico; see Latorre and Latorre 1977)

camphor-daisy [-weed] (“camphor” was taken into English from French *camfre* or *camphre*, ultimately from Greek *caphura* and Arabic *kafur*, a vegetable oil with a bitter taste and characteristic smell; in Eurasia, the compound was famous as an antaphrodisiac; by at least 1570 it was combined with other words to indicate distinctive species)

golden [gold]-aster (“golden,” in reference to color, has been combined with various plants since at least the 1570s, and probably before; the OED 1971 lists 33 combinations, and “aster” is not among them)

When I first arrived in Florida in 1970, I soon found three common species of golden-asters. No flora of the region had been published since Small’s (1933) *Manual of the Southeastern Flora*, so I used that book to identify the plants. One of them was *Pityopsis graminifolia*, another was *Chrysopsis floridana*, and the third was *Heterotheca subaxillaris*. The following year, Long and Lakela (1971) published *A Flora of Tropical Florida*, and two of the three names changed. Instead of *Pityopsis graminifolia*, they called it *Heterotheca graminifolia*. *Chrysopsis floridana* too was placed in the same genus and became *Heterotheca floridana*. Not knowing any better, I began following Long and Lakela (1971).

Then my friend John Semple (1977, 1980, 1996, Semple et al. 1980) studied the groups and put all three back in the genera where Small (1933) had them. He did, however, redefine those three genera.

At first, I resisted John’s changes, but I finally studied them in detail to see what he was talking about. *Heterotheca* contains 25 species and all are native to the southern parts of North America, but some extend to Argentina.

There are chemical differences, too, that Semple and his colleagues did not discuss. *Heterotheca subaxillaris* is the most fragrant of them, as witnessed by the common name comparing it with camphor. My students never had problems remembering it after smelling crushed leaves and hearing its common name.

Ajilvsgi (1984) wrote that livestock avoid camphorweed. That comes as no surprise although Semple had found herbarium specimens with notes that it “might be used as a forb locally.” He and my students agree they would be “very hungry cows.”

There is no record of indigenous or other people using camphor-weed in the United States, but Semple has seen herbarium labels indicating that Mexicans use them for medicine. It turns out that the “Mexicans” were displaced Kickapoo from southern Wisconsin who moved there in 1852 to avoid persecution in the United States. They used *H. subaxillaris* (reported as *H. latifolia*) to treat heat rash, burns, and itch, and to ease menstrual pain (Latorre and Latorre 1977).

Moerman (1998) found the Cheyenne, Hopi, Isleta, Luiseño, and Navajo using *H. grandiflora* and *H. villosa*, basically across the southwestern United States. It would be logical for a similar use to extend to the species through the southeastern states.

Martinez (1969) found *H. inuloides* was called *acahual* (from Náhuatl *acahualli*, dry herbs to ignite ovens), *false árnica* (false arnica), and *cuautepeco* [*akawtomitl*] (from Náhuatl *cuahuatl*, tree, and *teteco*, a passive form of the verb *teki*, to cut or to pick/pluck) in Mexico. In Aguascalientes, Chihuahua, Guanajuato, Hidalgo, Jalisco, Nayarit, Nuevo Leon, Oaxaca, San Luis Potosi, the Valley of Mexico, and Veracruz an alcoholic decoction of flower heads is used to treat bruises, toothache, stomach problems, and coughs (Vasquez and Jacome 1997). *Heterotheca inuloides* does not contain the alkaloids found in the European *Arnica montana* (Martínez 1969). Von Reis and Lipp (1982) found the same species recorded for the same use on a specimen collected by G.B.Hinton (847, GH?) in 1932. Altschul (1973) found that *H. leptoglossa* has been used to treat colds and flu in Mexico. Semple (personal communication April 2003) considers that taxon part of *H. inuloides*.

Both *H. subaxillaris* and *H. grandiflora* contain sesquiterpenes. Bohlmann and Zdero (1979) and Bohlmann et al. (1982, 1985) found cadinane derivatives in *H. subaxillaris*, and Bohlmann et al. (1979) and El-Dahmy et al. (1986) found cadinane and norcadinane derivatives in *H. grandiflora*. Wollenweber et al. (1985) found both flavonoid glycosides and resins in *H. grandiflora* and *H. subaxillaris* (as *H. psammophila*). Jakupovic et al. (1987) found humulene derivatives in *H. villosa*. A related species in the southeast, *H. camporum*, contains flavonoids with both insecticidal and antibacterial properties (Waage and Hedin 1985), although no records have been found that it was used as a medicine.

Hocking (1997) noted that *Heterotheca* contains “volatile alcohols, probably borneol.” Lincoln and Lawrence (1984) and Duschatzky (1998) described the volatile constituents of the leaves of *H. subaxillaris*. Soon afterward, Dellacasa et al. (1999) found that those essential oils exhibited antimicrobial activity against *Bacillus subtilis* and *Escherichia coli*.

Most of the chemical literature is on *H. inuloides*, probably because it is the most famous herbal medicine. The plant has long been known to contain coumarin, galangin, kaempferol, quercetin, and rhamnetin (quercetin 3,0 rhamnoglucoside) (Kubo et al. 2000, Delgado et al. 2001). It also contains sesquiterpenoids, as well as flavonoid aglycones, flavonoid glycosides, and terpine derivatives (Bohlmann et al. 1976, Jerga et al. 1990a,b,

Kubo et al. 1995, 1996, Haraguchi et al. 1997). A series of studies indicates that these chemicals are analgesic, anti-inflammatory, antimicrobial, and both cytotoxic and antioxidative (Kubo et al. 1994, 1996, Haraguchi et al. 1996, 1997, Gene et al. 1998, Segura et al. 2000, Delgado et al. 2001).

### *Hibiscus*

(Dioscorides, fl. A.D. 40–80, recorded the Greek name *ibiskos*, the mallow; Pliny, A.D. 23–79, used *hibiscus* and *ebiscum*, the marsh-mallow; Linnaeus reapplied *Hibiscus* and retained *Althaea officinalis* for the marsh-mallow)

### *Hibiscus moschatus*. From Britton and Brown 1897.

hibiscus (in use by 1706 when a book on European medicines included “*Hibiscum* or *Hibiscus*, the Herb Marshmallows, of known Vertue against the Stone and Gravel”); *ibisco* (Italian)

*ketmie* (from Arabic *khatmi*, the name of *Hibiscus esculentus*, French)

*Roseneibisch* (rose hibiscus, German)

*Stundenblume* (hour flower, German)

*Hibiscus moscheutos* (from its odor, suggesting the musk-rose)

breast-root (“In some parts of Virginia its root is used in the form of an emollient poultice in tumors of the breast, whence the name Breastroot,” cf. Castiglioni 1790 in Coffey 1993)

crimson-eyed rose-mallow [crimson-eyed rose-mallow]; mallow rose (New York)

marsh hibiscus [mallow]; [swamp rose, water] mallow

musk [musk-plant] (Ohio)

[common] rose mallow (rose-mallow was in use by 1731 when Philip Miller included the name in his *Gardeners Dictionary* for *Althea*; then Linnaeus called it *Hibiscus moscheutos*, to make the hibiscus the musk-

rose in 1753, but that was in Latin; rose-mallow was not applied to *Hibiscus* until Asa Gray used it in 1866)  
 wild cotton (a comment on the similarity of *Hibiscus* to *Gossypium*)

Europeans knew at least two species of *Hibiscus* when they arrived in the New World, although neither was native to most of Europe. *Hibiscus syriacus* (Syrian ketmia) and *H. trionum* (bladder ketmia) had both been introduced and cultivated. They were, however, quite familiar with the “mallows,” having used *Althea* and *Malva* for medicines since at least the times of Pythagorus (fl. 6th century B.C.), Hippocrates (ca. 460-ca. 377 B.C.), and Theophrastus (372–287 B.C.) (Porcher 1863, Meyer et al. 1999).

According to Jacques P. Cornut in his book *Canadensium plantarum* of 1635, these American plants resembled the *Rosa moscheutos plinii* (the Musk-Rose of Pliny). That herb is now the cultivated *Rosa moschata*, native across southern Europe, northern Africa, and western Asia, but naturalized in North America (Fernald 1950, Hortorum 1976).

The only record of indigenous use seems to be among the Shinnecock, who lived on what is now Long Island, New York. They used an infusion of dried *H. moschatus* stems to treat bladder infections (Moerman 1998).

Settlers, however, made great use of members of the Malvaceae. Porcher (1863) wrote simply that *H. moscheutos* “is possessed of demulcent properties; a convenient substitute for” *Malva rotundifolia*. That species he recommended because it “possesses valuable demulcent properties.... It is very emollient, and is employed in catarrhal, dysenteric, and nephritic diseases, and wherever a mucilaginous fluid is required. It is administered in the shape of emollient enema, and it forms a good suppurative or relaxing cataplasm in external inflammations.” He further noted that “*Pythagore regardait leur usage comme propre a favoriser l'exercice de la pensee*” (Pythagorus regarded its usage to help the exercise of thinking). And, he added, “Hippocrates employed it as we do, for gargles and collyriums, as an application to heated and inflamed parts, as a vehicle for pectoral and anodyne medicines, and for those administered in diseases of the urinary passages.”

Coon (1974) wrote, “Readers should learn to know the values in *all* the mallows.” He then recommended the infusions of the leaves, with one teaspoon of leaves to one cup of boiling water, “to loosen coughs and relieve sore throats, especially if honey is added to each dose.” He continued that it was also good for irritations of the bowels, kidneys, and urinary organs. Externally, he thought the members of the family were good for poultices for inflammations and bruises and for reducing the pain and swelling of bee and wasp stings.

Foster and Duke (1990) wrote that *H. moscheutos* “abounds in mucilage.” They noted that the leaves and roots, like those of related species and genera, were used as demulcents and emollients in treating dysentery, lung, and urinary ailments. Hocking (1997) listed the seeds as “cordial, stomachic, demulcent, emollient, nerve sedative; roots and leaves sedative.”

***Hieracium* (including *Pilosella*)**

(From Greek *heirax*, *heirakos*, hawk; Pliny, A.D. 23–79, believed that hawks ate the plants to sharpen their eyesight)

*tawohokv* [rawohokv, tawohokv, rawvhokv, tawvhokv] (Muskogee)

*Habichtskraut* (hawk weed, German); hawk-weed [hawkweed] (appeared in Anglo-Saxon about A.D. 1000; mentioned as medicinal in the herbals by William Turner in 1562 and John Gerarde in 1597)

*hårsveve* (*hårs*, hair, *veve*, weave, Norwegian)

*pilosella* (little hairy one, Italian); *piloselle* (French)

*sрубhan na muice* (pig's snout, Gaelic)

***Hieracium gronovii*** (in honor of Jan F. Gronovius, 1690–1762)

vein-leaf, [hairy] hawkweed

Norway has at least 24 “kinds” of hawkweed that are recognized (Mossberg and Stenberg 1994). A major problem in recognizing species in the genus is that there is so much apomixis that individual populations often seem distinctive (Fernald 1950, Mabberley 1997). Early experiments with genetics on this genus failed because it was not recognized that they were not outcrossing plants. Most of the plants are triploid or tetraploid apomicts and the modern trend is to call them “microspecies” (Mabberley 1997).

Hocking (1997) simply wrote that *Hieracium gronovii* was used medicinally. No other records have been found regarding this species, but Moerman (1998) lists seven others (including European *H. pilosella*) as having been given as a tonic, to treat diarrhea, and to help cure sores. These species were used by the Cherokee, Iroquois, Navajo, Ojibwa, Okanagan-Coville, and Rappahannock, people living from New England to Washington and British Columbia, and from the Carolinas to Arizona.

The wide distribution of the pharmacopoeias in which these *Hieracium* were used suggests independent discovery of their virtues. However, the European species were ancient remedies. John Gerarde wrote in 1597 of *H. aurantiacum*: “The decoction or the distilled water of this herbe taken inwardly, or outwardly applied, conduce much to the mundifying and healing of greene wounds; for some boyle the herb in wine, and so give it to the wounded patient, and also apply it outwardly.” Culpeper (1653) considered *H. pilosella* a “cooling, somewhat drying and binding herb for a wide range of ailments.”

Many species contain inulin. *Hieracium pilosella* contains antibiotic components, including umbelliferone and luteolin (Hocking 1997).

***Hippocratea*: Arthritis-Vine**

(Named for Greek physician Hippocrates, ca. 460-ca. 377 B.C.)

Twining up into the canopy of trees in swamp and hammock forests in southern Florida is a plant known locally as arthritis-vine. That name is applied because the nodes of *Hippocratea volubilis* (climbing) are swollen and look like the similarly inflamed joints of arthritic humans. Although appropriate, and useful to new students learning to

recognize the sometimes bewildering tropical species, that name is surely a recent application. Neither Chapman (1897) nor Small (1933) includes the vernacular name; they simply call it the “Hippocratea family” (Hippocrateaceae). More recently, Wunderlin (1998) dubbed the plants “medicine vine.”

While there should be multiple medical uses for plants with those common names, and with the generic name it has, there are not many listed. Indeed, Morton (1981) does not include the species, but discusses only *H. celastroides* from Mexico and Central America.

Linnaeus’s knowledge of the single species he described, *H. volubilis*, came completely from Charles Plumier and Pierre Barrere, explorers of the Caribbean. The choice to name these plants after that famous Greek physician followed the lead of Charles Plumier, who wrote, “*Hippocrates Cous, sen in Insula Coo natus.*” (Hippocrates of Cous, or growing on the island of Coo). Several of the species contain references to Greek philosophers, including Theophrastus and Dioscorides in the following two entries. There is nothing in the comments by these authors that the climbers are used for medicines. Further, Linnaeus did not cite his own *Materia Medica* for the species, although he had seen it in cultivation at the *Hortus Cliffortianus*.

The genus *Hippocratea* was named by Linnaeus for the Greek doctor Hippocrates, the son of Heraclides who was the contemporary of Herodotus, Socrates, Plato, and Democritus. Many books consider Hippocrates the “Father of Medicine.” Indeed, he had many “modern” ideas about medical practice, including advocating good diet, fresh air, clean water, and exercise. He separated medicine from philosophical speculation and mythology. He coordinated the available information on plant remedies and prescribed them when they appeared to be indicated by his diagnosis of the disease.

Not everyone agrees that the group should be split out into the distinct family Hippocrateaceae, which was created by Antoine Laurent de Jussieu in 1811. As a family, it contains more than 300 species, and is widespread in the tropics. Most species are traditionally put in either *Hippocratea* (100 to 120) or *Salacia* (200). Others divide *Hippocratea* into 12 genera and *Hippocratea sensu stricto* becomes monotypic (*H. volubilis*). Everyone agrees that those species are close to Celastraceae, and some include all the species within that family.

Regardless, Florida has the single species *H. volubilis*, which also grows in Cuba, Hispaniola, Puerto Rico, some of the Lesser Antilles, and from Mexico (Veracruz, Chiapas, Campeche, Yucatán) to northern Argentina. Oddly, the vines are absent from the Bahamas, Barbados, and Jamaica. Although not included in the recent *Flora de Nicaragua* (Stevens et al. 2001), the species does occur there. Perhaps the spotty distribution in the Caribbean is because the winged fruits are dispersed by wind. Some of the islands (e.g., Barbados) where the plants are not known are outside the “normal” reach of several wind-dispersed taxa.

Common names for the scramblers seem to focus on the fruits and colors. For example, several vernacular names compare the fruits to almonds (*Prunus dulcis*, Rosaceae). These comparisons include *bois z’amande* (almond tree, Guadeloupe, Martinique), *liane z’amande* (almond vine, Guadeloupe, Martinique), and *Waldmandelbaum* (forest almond tree, German). In Amazonian Brazil it is called *fava de arara* (macaw’s bean). Those comparisons are made because the seeds are edible, although somewhat bitter. Only Roig (1945) makes the comparison to taste with almonds, and the seeds are used to make *horchata*, a mixture of ground seeds, sugar, and water that

somewhat resembles a milkshake. The seeds contain 50% oil, which is odorless and colorless.

The Maya, because of fruit shape, say *tulubalam* (jaguar's ears, *t'ul*, long ears, *balam*, jaguar, Yucatán). Still, the Mayans exaggerate the resemblance to the feline's ears. The fruits are samaroid mericarps, usually three in a group, flattened, oblong or elliptic, and 4 to 6 or sometimes 8 cm long and about 3 cm broad. The fruits are not really much like the rounded ears of *Panthera onca*, but the Maya see some resemblance. Given the importance of this top predator in the Mayan pantheon, it would not be a surprise to learn that the name was an allusion to how well it could hear.

It is unclear whether or not the people who attribute colors to the climbers do so because of physical or medical properties, or some other reason. Regardless, in Puerto Rico and Brazil *H. volubilis* is considered a *bejuco prieto* (black vine) or *cipo preto* (black vine). Yet to the Haitians it is a *liane blanche* (white vine), while it is *liane rouge* (red vine) in Guadeloupe and Martinique. These colors are not obvious in cut stems, so they must come from some other source.

Two names are possibly medical allusions, although one of them is questionable. In Cuba, it is *amansaguapo* (man tamer), either a medical commentary or the result of someone trying to pass through a tangle of the stems. Perhaps, instead, that name is related to the Hispaniolan application of the slender stems as substitute ropes (Liogier 1974). However, the name *bejuco de vieja* (old woman's vine, Cuba) is surely identical in allusion to "arthritis vine."

No meanings have been found for three names. However, *jaiquimey* (Hispaniola) shares syllables, although not their sequence, with the common (*jaimiqui*) and specific names (*Manilkara jaimiqui*) applied to the wild sapodilla (Sapotaceae). It may be that all three words are based on the name of the island Jamaica. The Hispaniolan name *mayit* resembles a Taino word, while *zorain* might be "disorder" (z, of the, *orain*, alternate spelling of *orage*, or disorder, Haiti), in reference to the twining stems. Another reference to twining stems is barracuta tietie in Belize, where they make cords of them (Balick et al. 2000).

Although people use the plants as medicines, that apparently is not a common application. In Cuba, the seeds produce an emollient oil, and the flowers and leaves are pectoral, i.e., good for inflammation of the chest and larynx (Roig 1945). The *horchata* made from the seeds is considered tasty and pectoral. Comments by Standley (1920–1926) suggest that historically *H. volubilis* was more important as a pectoral, and as a remedy for snakebite. In Brazil, plasters of leaves are used to cure infected sores (LeCointe 1945), to control coughing, and as an expectorant (Roig 1945, Mors et al. 2001). According to Roig (1945), the flowers and bark are a febrifuge.

Other species in the genus are better known for different applications. Related species in Mexico are made into a tincture or paste used to kill parasites on the human body (Standley 1920–1926). Some examples include *H. acapulcensis*, which is called *hierba del piojo* (Michoacan, Guerrero), *cuanabichi* (louse-killer, Zapotec, Oaxaca), *mata-piojo* (louse-killer), *hierba del piojo* (louse herb), *bejuco de piojo* (louse vine), *pepitas de piojo* (louse eggs), and *semillas de piojos* (louse eggs). Similarly, people in Yucatan are recorded as taking a decoction of *H. celastroides* as a tranquilizer (Morton 1981), in addition to using it to kill lice on humans and animals. Maybe the name knot vine for the Australian species *H. barbata* also indicates medical use.

There are a number of bioactive compounds within the genus *Hippocratea volubilis* contains triterpene alkaloids (Alvarenga and Ferro 2000), and other species have benzyl isothiocyanate, cyanogenic glycosides, essential oils, quinones, saponins, sesquiterpenes, triterpenoids, and volatile compounds (Palacios et al. 1989, Mata et al. 1990a,b, Calzada et al. 1991, Iwu et al. 1991, Mata 1993, Calzada and Mata 1995, Perez et al. 1995, Jimenez-E. et al. 2000). These chemicals have antibacterial properties, and are antiinflammatory (Iwu et al. 1991, Pérez et al. 1995).

Considering all the applications that people have made of the plants in the Americas, it seems curious that the genus *Hippocratea* appeared in the journal *Economic Botany* only four times in the first 50 years of the journal's existence (Kaplan 2001). Of those times, there is only a single reference to American species (Palacios et al. 1989). The others are comments on Old World species (Irvine 1952, Jain and Trarafder 1970, Secoy and Smith 1983). At least two factors are involved in that paucity of mention. The first factor is the generally ready availability of more dependable and better substitutes for the nutritional and medical applications formerly given *Hippocratea*. The second factor must be the continued destruction of the forests where these vines grow. These two factors, although usually considered independently of each other, are working to erode the knowledge we humans formerly had of the living world around us. We are sterilizing our surroundings and putting limits on our imaginations.

### *Hippomane*

(Theophrastus, 372–287 B.C., used the Greek words *hippo*, horse, and *mania*, madness because the fruits of the original plant, some say *Datura stramonium*, made horses crazy when they ate them; Linnaeus substituted the name for an American plant) Oviedo gave perhaps the first account of these trees in the 1500s. He wrote that the milky juice was used by islanders to make poison arrows. The fruits and sap are poisonous internally, although some react to juice on the skin, while others are immune (Standley 1920–1926). Dry fruits are considered safe enough to use as a diuretic (Duke 1972). Smoke from burning wood causes inflammation of eyes; crabs that eat the fruits are poisonous if consumed by people (Duke 1972) but goats that eat the fruits are not. Seeds and bark are used as a vermifuge, but dangerous (Petersen 1974). Gum from the trunk is used against dropsy and venereal disease in Jamaica and elsewhere (Morton 1968, 1981, Petersen 1974). Writing in 1673, Richard Ligon noted: “The people who have lived long there [Barbados], say, ‘tis not wholsom to be under the shade of this tree. The fellers, as the cut them down, are very careful of their eyes; and those that have Cipers, put it over their faces; for if any of the sap fly into their eyes, they become blind for a month.... Yet, of this timber we make all, or the most part, of the Pots we cure our Sugar in; for, being sawed, and the boards dried in the Sun, the poyson varpours out.... The fruit is like an apple *John*, and ‘tis said to be one of those poysons, wherewith the Indian Caniballs envenome their arrows” (Ligon in Standley 1920–1926).

***Hippomane mandnella*.** a. Terminal bud with stipule, b. Leaf outline, c. Base of leaf, with petiolar gland, d. Flowering branch, e. Detail of flowering spike, with renewal bud in axil of leaf to right, f. Staminate flowers, with and without perianth, g. Diagram of staminate flowering unit (glands cross-hatched), h. Pistillate flower, longitudinally dissected, i. Diagram of lower flowering unit with pistillate flowers, staminate flowers, and glands, in three different arrangements, j. Twig with fruit, k. Fruit in transverse section. *Drawn by Priscilla Fawcett. From Correll and Correll 1982.*

***Hippomane mandnella*** (little apple)

*arbol de la muerte* (tree of the dead, Oaxaca)

*hinchahuevos* (swollen testes [literally, eggs], Mexico)

*kinsah-uinik* (*kinsah*, kill, *uinik*, man, Maya, Yucatán)

*manchineel* [*mancanila*, *manzanillo*, *manchaneel*] (little apple, English and Spanish variants, Oaxaca, Veracruz, Cuba, Puerto Rico, Dominican

Republic, Belize, Panama, Colombia, Venezuela, Virgin Islands);  
*manzanillo de la playa* (little beach apple, Puerto Rico)  
*pinipiniche* [*penipeniche*] (Cuba)

### *Hordeum*

(The ancient Latin name applied by Cato, 234–149 B.C., to Pliny, A.D. 23–79; akin to Latin *horreum*, a storeroom, Akkadian *qaritum*, *qiritu*, granary, storeroom, Hebrew, *qorah*, beam, roof)

barley (from Old English *baerlic*, of unknown origin; in use by A.D. 966);  
 barley-corn (in use by A.D. 1382, “corn” meaning grain)

*barli-arisi* [*barlhi arisi*] (Tamil); *barlibiyam* (Telugu)

*bygg* (Norwegian, for *H. vulgare*); *toradsbygg* (Norwegian, for *H. distichori*)

*cebada* [*sevada*] (San Luis Potosi); *cebada comiin* (Spain); *cevado* (from Latin *cibare*, to eat, feed, Portuguese)

*chaîr* (Tunisian)

*dreche* (French)

*eòrna* (Gaelic)

*eiwt* (Coptic)

*Gerste* (German)

*juba* [*jau*, *jeb*, *joo*] (Bengali); *yuva* (Sanskrit) *orge* (from Latin *oryza*, rice, Quebec); *orzo* (Italian)

*seorah* (pi. *seorim*) (Hebrew); *si 'yr* (Modern Egyptian Arabic)

### *Hordeum pusillum* (very small)

little barley

Both two-rowed barley (*Hordeum distichon*) and common barley (*Hordeum vulgare*) were essential grasses to Europeans at the time of contact with the New World. Barley was a critical source of malt used in manufacturing beer and whisky (Uphof 1968). The grains were also important elements in the diets of many Europeans. Old World people were also familiar with several other species, including the six-rowed barley (*H. hexastichon*), which has been found in the ancient tombs of Egypt (Manniche 1989, Hocking 1997). *Hordeum* is a genus of about 20 northern temperate species, with 8 in Europe (plus cultigens) (Mabberley 1997).

*Hordeum pusillum* was named by Thomas Nuttall in 1818. The species grows from Delaware to Washington, south to Florida, Louisiana, Texas, New Mexico, and Arizona (Fernald 1950, Kearney and Peebles 1951).

It has been known for some time that little barley was cultivated 2000 years ago by the Hohokam of Arizona (Gasser 1982, Asch and Asch 1985). Gayle Fritz also identified it in the Spiro site of Oklahoma (Yarnell in Asch and Asch 1985). However, it was not until somewhat later that it was realized that it also was cultivated in Illinois (Asch and Asch 1985).

Little barley may be one of the dominant “seeds” (caryopses) in Late Woodland or Mississippian archaeological sites, and dates to 2550–2770±70 B.P. (600–800 B.C.). More recently, Fritz (2000b) concluded it was domesticated by 2000 B.P. However, little barley was one of several highly nutritious native foods in the Eastern Agricultural Complex that was abandoned when maize became the predominant American grain (see also *Chenopodium*, *Helianthus*, *Phalaris*). Moerman (1998) did not mention this species.

### *Hydrangea*

(From Greek *hydor*, water, *angeion*, *aggeion*, a vessel, referring to the shape of the fruit)

***Hydrangea arborescens*** (becoming tree-like)

hill-of-snow

[American, mountain, smooth, wild] hydrangea

seven bark[s] (the herbal drug from *H. arborescens*)

***Hydrangea arborescens*.** From Britton and Brown 1897.

In the 1730s, John Clayton visited an inland area and returned with a plant he had never before seen. He knew that he had found something different because he wrote on the specimen label, “*Novum genus pertinens a polyandria monogynia*” (New genus belonging with those of many stamens and one gynoeceum).

Clayton sent the specimen to Europe where his colleague Jan Gronovius in the Netherlands studied it for the flora. Gronovius agreed with Clayton’s assessment, and called the plants *Hydrangea* in his *Flora Virginica* published in 1739–1743. Linnaeus also concurred and called the shrubs *H. arborescens* in 1753.

In 1756, Dr. Alexander Garden of Charleston returned from a trip to the Cherokee country in the mountains. He brought back with him “the *Hydrangea* of Gronovius” (Vogel 1970). Clearly both of these early plant explorers had learned about the plants from the Cherokees because Mooney later recorded this tribe using *Hydrangea* roots in a decoction with other plants to treat women who “had strange dreams during their menstrual period” (Vogel 1970). Mooney got his information from the “Swimmer Manuscript,” a series of prescriptions written by *A ’yuninis*, his Cherokee shaman informant.

That was not the only use to which the Cherokee put these shrubs. They also used *Hydrangea* to regulate menstrual periods, to stop vomiting, as an emetic, a purgative, and an antiseptic, to treat burns, tumors, ulcers, stomach trouble, high blood pressure, sprains, and swollen muscles (Hamel and Chiltoskey 1975). From another report, Moerman (1998) found that they also made tea from peeled twigs, and fried them like green beans. The Delaware used *H. arborescens* to treat gallstones (Moerman 1998).

That limited information is what has been found about indigenous people using a plant that has a wide range in the eastern states. *Hydrangea arborescens* grows from New York to Florida, and west to Oklahoma, Arkansas, Missouri, Indiana, and Ohio (Fernald 1950). It is mostly an Appalachian species and on the southern part of its range is most abundant in the northern half of Georgia. There are relict populations in Liberty and Walton Counties in the Panhandle that are considered endangered within Florida (Coile 2000). Although the plants are rare in some regions because of habitat destruction, they have been brought into cultivation. Brickell and Zuk (1997) list four formally named cultivars of the species.

People after physician Alexander Garden in the 1750s continued using these shrubs as medicine. Although neither Porcher (1863) nor Millsbaugh (1892) mentions the plants, they were important to the medical community in the early 1900s. Culbreth (1910) recommended the plants as a “[d]iuretic, narcotic; renal and cystic calculi.” The dried underground parts were official in the National Formulary between 1916 and 1926 for diuretic and diaphoretic applications (Vogel 1970). Felter (1922) said that *H. arborescens* was a “diuretic and sedative to cystic and urethra irritation, with passage of gravelly urine. It does not dissolve gravel, but is believed to be of value in preventing their formation, especially alkaline and phosphatic concretions.” Krochmal and Krochmal (1973) give much of the same information, but add that the plants were used in colonial times to treat kidney stones.

Currently Bown (1995) suggests that this hydrangea serves as follows: “Internally for kidney and bladder stones, cystitis, urethritis, prostatitis, rheumatoid arthritis, gout, and edema. Works well with [Breakstone parsley] *Aphanes arvensis*, [Joe-Pye weed] *Eupatorium purpureum*, and [Bearberry] *Arctostaphylos uva-ursi*. Excess may cause dizziness and bronchial congestion.” Hocking (1997) wrote that they were “[d]iuretic in kidney stones, cathartic, said to be narcotic.”

However, these are not plants to be use without caution. As Foster and Duke (1990) reported, “In experiments, [*H. arborescens*] has caused bloody diarrhea, painful gastroenteritis, and cyanide-like poisoning.” That result is not surprising as the plants contain hydrangin and neohdrangin (glycosides), volatile oils, and resins (Hocking 1997, Duke 2003).

### *Hydrocotyle*

(Greek *hydro*, water, *kotyle*, a shallow cup, in reference to the peltate leaves of some species)

*escudela da agua* (water shield, Portuguese); *escuelle d'eau* (water shield, French)

*lus na-peighinn* (penny herb, Gaelic)

***Hydrocotyle umbellata*.** a and b. Habit, c. Fruit, d and e. Flower, side view. f. Flower, top view, a, c, and d drawn by Vivian Frazier. From Correll and Correll 1972. b, e, and f drawn by K. Vitkus. From Institute of Food and Agricultural Sciences.

penny-wort [pennywort] (comparing the round leaf with a coin, this name has been used in English since ca. 1400 for *Umbelicus*, Crassulaceae. By contrast, *Hydrocotyle* was not named for the coin, but from its similarity to *Umbelicus*. Henry Lyte wrote in his 1578 translation of Dodoens's herbal that the name was used "[b]ycause of certayne similitude...that it hath with Pennywurte of the wall [*Umbelicus*]"

*skjoldblad* (shield leaf, Norwegian)

*soldinella aquatica* (little water coin, Italian)

*Wassernabel* (water navel, German)

***Hydrocotyle umbellata*** (having partial or secondary umbellate flower clusters)

*acariçoba* (*waka'ri*, with a shell, *çoba*, living, Tupí, Brazil)

*berro macho* (male cress, Venezuela)

*erva de [herva] capitão* (captain of herbs, Brazil)  
*locatokokocihiliswâ* (*lucv-svoke*, box turtle, *heleswv*, medicine, Creek);  
*loksittish* (*loksi'*, turtle, *ittish*, medicine, Chickasaw); *yokcapolo:ckayikci*  
 (spherical turtle, i.e., box turtle medicine, Mikasuki)  
*nickels-and-dimes* (Texas)  
*ombelico de Venus* (Venus's navel, Texas, Puerto Rico)  
 [umbrella water, marsh, water] penny-wort (USA, Puerto Rico)  
*quitasolillo* (little parasol, Cuba)  
*sombrerillo de agua* (little water hat, Puerto Rico)  
*takpahule* (Mikasuki, Bennett 1997)  
*yerba de cuatro* (herb for four, Puerto Rico)

Linnaeus created *Hydrocotyle* in 1753, accepting a generic name proposed by Charles Plumer in 1703. At the same time, he named *H. umbellata*, which Marggraf and Piso had called *erva de capitao* and *acariçoba* in 1648. Linnaeus knew five kinds, although now *Hydrocotyle* is known to be a near-cosmopolitan genus containing perhaps 130 species (Mabberley 1997).

Pittier (1926) recorded use of the juice and root against leprosy in Venezuela. In Cuba the plant is considered aperitive and diuretic, but in higher doses emetic. *Hydrocotyle umbellata* is used against rheumatism and for liver and intestinal problems (Roig 1945). Seminoles use the plant to treat "Turtle Sickness" (Sturtevant 1955), and as a remedy for asthma and pneumonia (Bennett 1997).

### *Hymenocallis*

(Greek *hymen*, membrane, *kallis*, beautiful, an allusion to the membrane uniting the stamens, the staminal cup)

*Hymenocallis latifolia*. Drawn by  
 R.N.Honychurch.

***Hymenocallis latifolia*** (broad-leaved) chrysolite lily  
*liria sanjuanera* (St. John's lily, Cuba)  
*lirio de playa* (beach lily, Puerto Rico)  
 [Cayman Islands] spider lily (USA, Caymans)

Philip Miller called these plants *Pancratium latifolium* in 1768. It was not until 1812 that Salisbury realized that the tropical plants were distinct from the temperate *Pancratium*. Now there are 30 to 40 species of *Hymenocallis* known from warm regions around the world (Mabberley 1997).

Bulbs are used to heal wounds, and flowers are pectoral (Roig 1945). Several other species in the genus are used in the Caribbean for a variety of ailments (Morton 1981). Like their relatives *Crinum*, these species contain lycorine and other alkaloids; yet most species are used in the Caribbean as medicines (Perkins and Payne 1978, Lampe and McCann 1985).

### ***Hypericum*: The Saint's Weeds**

(*Huper*, above, *eikon*, image, alluding to an idol or spirits [apparitions], or both; probably meaning that the plants had power over evil)

*Hypericum. Hypericum fasciculatum.*  
 a. Upper part of plant, b. Bud. c.  
 Flower, d. Capsule. *Hypericum*  
*galioides*. e. Capsule. Drawn by Vivian

*Frazier. From Correll and Correll*  
1972.

Once you learn some plant names in Florida you cannot help noticing how our wild areas have been affected by saints. Flatwoods has St. John's wort; scrub has other species. Different kinds of St. Andrew's cross are found in flatwoods and hammocks. Wetlands have St. Peter's wort. How saints' names became attached to Florida plants is a story reaching back to seasonal astronomical events and pre-Christian eras. My introduction to the saga began in the Amazon basin.

In June of 1969 my wife and I were studying plants near the Amazonian town of Belem, Brazil. We were living in a guest residence called *Hotel Acai* at the *Institute Agropecuaria do Norte*. As the end of the month drew near, dozens of people gathered on the institute grounds in a great open area and began piling up stacks of wood for bonfires. Having never before seen the Midsummer Festival, we attended the party that accompanied those large fires on the night of 24 June. It was a novel experience for two people of northern European heritage to witness a ritual that began long before Christianity spread through Europe. The festival remains firmly entrenched in the cultures of several southern European countries and traveled with their immigrants into the New World.

We noticed at the time that the date was near the Summer Solstice (21 or 22 June), and that was the ultimate beginning of the tradition. All over the world ancient people celebrated the Summer Solstice or Midsummer's Day because that is the point at which the sun stops its northern travel and returns south toward the equator. Indeed, several groups of people believed that, if the deities were not placated, the sun would continue north and the world would end.

Romans not only burned fires, but they also threw in plants that had just begun opening their yellow flowers, and were considered "sun-symbols." Romans and Greeks believed that the bright flowers were sent by the gods to provide a holy sacrifice to repel evil of all kinds, not just to compel the sun to return. Those plants were *hypericum* in Latin; the Greeks called them *hupereikon*. A different interpretation was offered by Walker (1976), who suggested that the old Greek name *hupereikon* was derived from *hypo*, approaching, and *ereike*, heather. Regardless, centuries later, those words would be transformed into the plant genus *Hypericum*, including the plants now also called St. John's wort, or St. Andrew's cross, or St. Peter's wort. Spanish speakers still sometimes call them *hipericon*, and Italians *iperico*. The Norwegians have retained part of the old Greek with *perikum*.

Romans also called the plants *fuga demonum* (demon chaser, Latin), and the French changed this to *chasse-diable* (chase the devil), the Dutch to *hexenkraut* (spell-herb), and the English to devil's scourge. Other names include amber (from their scent resembling ambergris), sweet amber, balm-of-warrior's wound, cammock (*camag*, for bent, curl, temple, Gaelic), Klamathweed (named for the Klamath River in California, where the European plants were first introduced), *lus Chaluim Chille* (St. Columba's herb, Gaelic), *lus na fala* (bloodwort, in reference to red extract, Gaelic), *lus an fhògraidh* (banishment herb, Gaelic), rosin-rose (Dioscorides wrote that the seed "is like in smell to the rosin of the pine"), and witch's weed (surely an allusion to use by women herbalists). The name *achlasan* [*seid, seun*] *Chaluim Chille* (St. Columba's oxtetful [armpit package], Gaelic)

alludes to St. Columba using the *Hypericum* in an ointment under the arms of a stressed shepherd to calm his nerves (Beith 1995). Gaelic speakers also call them *eala-bhuidhe* [*ea-la-bhuidhe*] (*eòlas*, knowledge of healing incantations, *bhuidhe*, yellow, Gaelic). That name became corrupted and led to the herbs being called cola-weed and cola-weed.

French speakers also call it *millepertuis* (1000 openings), *toute-sainte* (all saints), *tout-same* (healall), or *tusane* (all wholesome). The French names are related to touch-and-heal and *tusan* of the English and Irish. The English say they use the name because the leaves are “touched” by their many dots. The name tipton-weed is related. Gaelic speakers also say one species is *beachnuadh boireann* (female St. John’s wort); another is *beachnuadh firionn* (male St. John’s wort). No one seems to be able to translate the first part of the name.

By the 1500s, Europeans had all been exposed to the Christian religion, and it had changed the names of many plants. By or before 1538, names for *Hypericum* were *saynt lohans wurt* or *saynt Johannes worte* (St. John’s plant, Old English). Cornish speakers had the same name but spelled it *losow sen Jowan*. It was also *saynt lohns grys* (St. John’s grass, Old English). The Germans and Dutch said it was *lohns kraut* (John’s plant), and later *Johanniskraut*. In Sweden it is *Johannis ort*. To the Spanish it is *hierba de San Juan*, and in Portuguese *erva de Sao João*. Names like God’s-wonder-plant, penny-John, and speckled John are related.

All these references to saints were part of the *modus operandi* of the Christian priests working to convert people from other religions. When the priests discovered they could not stamp out the pagan festivals and ideas, they simply adopted and incorporated them, with the appropriate saints or festivals, into their own system. That amalgam satisfied both the converters and convertees. First, the priests used St. John because his birthday was on 24 June. That was close enough to the Midsummer Festival to work. Since the *Hypericum* blossoms begin near then, it was even better. Best of all, the plant was supposed to bleed on 29 August, the anniversary of St. John’s beheading. All of the European names were originally applied to *H. perforatum*, but modifiers were tacked on for related species. For example, among others, the English recognize Irish, trailing, and marsh St. John’s worts.

When the New World was discovered many species of *Hypericum* were added to the growing roster, including *H. fasciculatum* (with leaves in bundles). European St. John’s worts have five petals; in the New World there are species with four petals, such as *H. hypericoides* (resembles *Hypericum* because it was previously placed in *Ascyrum*). These four-petal species were seen as plant versions of St. Andrew’s cross because of their X-shape. So, around 1613, St. Andrew was added; then St. Peter was enlisted. St. Peter, the acknowledged gatekeeper of heaven, was included because of the St. Petertide festival on 29 June. This gatekeeper was depicted holding keys crossed into an X. So, both St. Andrew and St. Peter were originally tied to four-petaled flowers.

People occupying the Americas also had names for the plants. The Cherokees said *kowaya yust’* for *H. hypericoides*. Alabama speakers called the same plant *omagaga*, while the Koasati said *winihka ahissi* (*winihkd*, thunder, *ahissi*, medicine). To the Creeks *H. fasciculatum* was *cissiwilano:ma*: (*cesse*, rat or mouse, *welvnwv*, feces), and their relatives the Miccosukee said *cisilaykô: mî*. Both have the same meaning, presumably in reference to the seeds. The Houma said *bois de mare cage* (swamp bush).

Moreover, Americans and Europeans had similar uses for different species. Leaves of some species have been used in salads or to flavor liqueurs (Bremness 1994). Flowers have made appealing red and yellow dyes. Among the Old and New World people *Hypericum* was used in medicines. The most ancient remedy was to promote healing (e.g., balm-of-warrior's wound), and Greeks called one kind *androsaemon* (man's blood). Externally, the plants have been applied to heal cuts, wounds, burns, hemorrhoids, and varicose veins (Bown 1995). Extracts of flowers are antiviral, astringent, diuretic, and sedative, and are used to treat inflammation and diarrhea, and to improve blood flow. Research is ongoing to test for possible use in treating AIDS; PubMed (2003) returned 28 papers published since 1989 on that topic alone.

Probably the best-known current use is against nerves and depression. Most new books on medicinal plants recommend them, especially for women undergoing depression associated with menopause. However, Duke (1997) says that eating a bagel or biscuit for breakfast may be just as advantageous. There is a link between high-carbohydrate diets and higher levels of serotonin, and that is the chemical promoted by St. John's wort.

Not many of the recent books on herbal medicines mention bad side effects. One of the best-documented problems among those using St. John's wort is that it can cause dermatitis, or worse, photosensitization (Tyler 1993). The compound responsible for this is a reddish dianthrone pigment called hypericin. So, you have a big problem if you use *Hypericum* and then turn red like a boiled lobster after a few minutes in the sun. The reaction in some white sheep and cattle that accidentally graze on the herbs is so dramatic that they die. People have not died from using St. John's wort as medicine, but walking around looking like a boiled lobster could result in deepening the depression one had hoped to cure.

# I

## *Ilex*

(Latin *ilex*, *elex*, ancient name for European holm oak tree, *Quercus ilex*)

***Ilex cassine*** (from Muskogee *esse*, leaf or *vsse*, tea)

*ahihátkí* [*ahe hatke*, *aheke*] (*ahe*, tree, *hatke*, white, Mikasuki)

*dahoon* (maybe from French; in use when Catesby visited the Carolinas, 1720s); *houx d’Ahon* (W.R. Gerard in Hale 1891 gave this French spelling; from *houx*, holly, *d’Ahon*, an attempt at the Catawba word *yaupon*; maybe the source of *dahoon*)

*helok hakv* (*helukwv*, black gum, *enhake*, resembling, Muskogee)

*inlokci*: *ca*: *tí* (*enlowake*, bud, *cate*, red, Creek)

*yanilla blanca* (white yanila, based on the Taino word *yana*, Cuba)

***Ilex glabra*** (without pubescence)

gallberry (Florida)

*ittohissishalokpa* [*ittohissikalokpa*, *ittishalokpa*, *itichalokpa*] (*itto*, tree, *hissi*, hair, *ishalokpa*, sharpening tool, Alabama)

***Ilex vomitoria*** (regurgitating; from the southeastern custom of using it as an emetic)

*aatichoosandyli* (*aati*, Indian, *ichoo*, mouth, *sanay-li*, twist, Alabama)

*Apalachine* [*the des Apalaches*] (Apalachee tea, early French visitor records, Florida Panhandle)

*asi* [*assi*] (Hitchiti-Mikasuki); *esse* [*assi*, *ussie*] (leaves, Creek, Muskogee; compare with *vsse*, tea); *cassina* [*cacina*, *cazina*, *cassine*, *cassena*, *cassiana*, *cusseena*] (1696 or before, derived from Creek *assi* or *assin*); *cassiné* (Timucua, fide Crawford 1988); *cossine* (Geary 1955 gives this as a person’s name; a loan-word?); *usi* (based on *usinola*, the black drink singer, Apalachee); *vsse* [*vs’se*] (tea, Muskogee)

*asilakm* (*asi*, leaf, *lakni*, yellow, Mikasuki; maybe this species)

*assi lupub’ski* (*assi*, leaves, *loputke*, small, Creek; cf. Hale 1891)

*awotaicita* [*sawatcka*] (*vwoticetv*, to make vomit, Creek)

black drink (a name given by British traders, cf. Hale 1891; notably, the term “black drink” is not used by Catesby, Romans, or Bartram; perhaps first used by Williams in 1837; the name is not given in the OED 1971, but Hudson 1979 said it was in use by the 1600s)

*canâ:fili* (simple term, Mikasuki); *cand:fildpi* [*cand*: *fild*: *pi*] (*canâ:fili*, *cassine*, *d:pi*, tree, Mikasuki)

*chocholate del indio* (Indian chocolate, Mexican visitors among Tawakoni Wichita, Texas)

*cowwta oucoroge* (Cherokee, North Carolina)

*esta hoola* (Bartram [1791] 1958 said this meant “the most beloved,” or “beloved tree,” Choctaw, Louisiana; Swanton 1931 glossed it *isht*, most, *ahollo*, beloved; Byington et al. 1915 translated the phrase as “magnificent, miracle” or “conjunction”; used to “make rain,” as reported by Romans [1775] 1961)

*Ilex. Ilex cassine* (left). *Ilex vomitoria* (right). Both drawn by P.N.Honychurch.

*foskey* (Yemasee; cf. Hale 1891)  
*hishi [asi]* (leaves, Chickasaw; singer: *taloowa'*)  
*hoyani:cî* (from Creek *mikkohoyani:cî*, chief physic; perhaps confusion with another species, cf. *Salix humilis*)  
*isu [isota]* (herb, Timucua; Le Moyne recorded that the singer chanted *Ha, he, ya, ha*)  
*ittokchakko* (*itto*, tree, *okchakko*, blue-green, Alabama)  
*ka'tchit* (to drink, Chitimacha; questionable identification; cf. Hudson 1979)  
*katsgimilpa* (catfish eat it; *katsg*, catfish, *im*, its, *ilpa*, food, Alabama)  
*no'ut* (Chitimacha, Louisiana)  
*te' del indio* (Indian tea, early Mexican visitors among Tawakoni Wichita, Texas)  
*wai't'i* (Chitimacha, Louisiana delta)  
*yaupon* [*yopon*, *youpon*, *yupon*, *uupon*] (derived from a coastal Carolina Catawba language, *yópon* or *yă'pă*, diminutive of *ḡyap* [*ye'p*, *yo'p*, *yup*], tree, 1709); related to Biloxi names for *I. opaca*, *apso'nd ayudi'* (*psûnti*, sharp-pointed; so called because of thorns), and Catawba

*yap?*

*ha hitce* (tree leaves sharp)

Although Catesby (1734–1747) knew that *dahoon* and *cassine* were two species, Linnaeus created confusion in 1753 by including both under the name *Ilex cassine*. It was not until Daniel Carl Solander (1733—1782) and William Aiton studied them in 1789 that the original *cassine* became known, through a technical problem, as *I. vomitoria*. Hedrick (1919) and Yanovsky (1936) still had the commonly used species listed incorrectly under *I. cassine*. Native people knew all along which was which.

Muskogean people called *I. cassine*, *ahihátki* (Mikasuki) or *inlokci:ca:ti* (Creek). Perhaps it was the Catawba who dubbed it *dahoon* (1720s, or before), at least the “Carolinas by Col[onel] Bull’s plantation” is where Catesby found the name used. Much later that plant became henderson-wood (Carolinas) or *yanilla blanca* (white little *yana*, comparing it to *Conocarpus erectus*, Taino, Cuba).

Sturtevant (1955) found the plant used as a soap substitute. The leaves are sometimes dried, roasted, and sold for use as tea along the South Atlantic Coast (Morton 1968b). In some they produce dizziness and have a laxative effect. Fruits are cathartic (Morton 1968, 1974).

Modern Seminoles use the stems as firewood, but they make a “smoky old woman’s fire” (Bennett 1997). They still use it as a medicine, but are not willing to share that information. Otherwise, children mash the fruits, and blow them through tubes to make bubbles (Bennett 1997). Perhaps children are imitating a medicine man as he prepares other plants.

The original *cassina*, now known as *I. vomitoria*, was the basis of indigenous secular and ritual practices. People throughout southeastern North America knew this plant (Hudson 1979). To the Timucua, it was *isu*, *isota*, in spite of the fact that the *American Heritage Dictionary* (2000) says their word was *cassine* [*kasine*]. Probably, the Timucuan word is a cognate or a loan-word for the Creek *asi* (Crawford 1988).

By at least the 1600s (Hudson 1979), a ceremonial beverage used throughout the range of the plants came to be called black drink. The Seminole leader, who became known as Osceola, was in fact called by his Hitichiti or Miccosukee title, *asi yahola* (black drink singer). In other Muskogean languages that title was based on *hishi' taloowa'* (*hishi'*, leaves, *taloowa*, singer, Chickasaw), *vsse yvhikv* (*vsse*, tea, *yvhikv*, singer, Muskogee), and *usinola* (*usi*, tea, *inola*, singer, Apalachee).

Some think that *I. glabra* may have been one of the hollies used in the black drink of the southeastern Indians. That is unlikely because, as the common name “gallberry” implies, the leaves and fruits are bitter and the whole plant is emetic (Morton 1974). Plants are now being used in xeriscape with success. The Alabama call it *ittohissishalokpa* (Swanton 1928a, Sylestine et al. 1993), but that is not likely to become a trade name.

### *Impatiens*

(From Latin *impatiens*, impatient, alluding to the explosive release of seeds when the ripe capsule is touched)

*Impatiens capensis* (erroneously thought to be from the Cape of Good Hope, Africa)

[orange, wild] balsam [weed] (“balsam” came into English from Latin *balsamum*, about A.D. 1000, meaning an aromatic vegetable juice; the word was applied to *Impatiens* before 1542; “weed” was added later)

jewel-weed [jewelweed] (“jewel” is derived from Old French *joel*, a word with an uncertain etymology, maybe from Latin *jocalis*, game, but always meaning an article of great value; applied to these American plants by 1890 because of the “earring-like shape of the flowers, and the silvery sheen of the under surface of the leaf in water,” OED 1971)

lady’s earrings (from the “earring-like shape of the flowers”)

quick-in-the-hand

*Impatiens capensis*. a. Habit, upper branch of plant, b. Basal part of plant, showing roots, c. Flower. Drawn by Vivian Frazier. From Correll and Correll 1972.

[spotted] snap-weed

[spotted] touch-me-not (“touch-me-not” was originally applied by John Gerarde in 1597 to the squirting cucumber, *Cucumis asininus*; the name was reapplied to *Impatiens noli-tantere* about 1659)

*tapasj*: ‘wi su’re (flower wild, Catawba)

*twatubigo’niak* (Potawatomi)

wild [brook] celandine (“celandine” appeared in English in A.D. 1310; from Latin *chelidonia*, Greek *chelidonium*, the swallow; the name derived from a legend going back to the classical Greeks and Romans that the

plant flowered at the times the swallows arrived in the spring, and withered when they migrated south in the fall; originally applied to *Chelidonium*, Papaveraceae; later applied to several genera)

Linnaeus and other Europeans knew their species, *Impatiens noli-tangere*, variously known as touch-menot, yellow balsam, and quick-in-hand, long before finding another species in the New World. That species, ranging from Europe to the Kamtschatka peninsula of Russia, and south to Japan and China, has long been noted as a laxative and diuretic, and has been used to treat wounds (Uphof 1968).

Of all the uses by indigenous people, the most famous is to stop the rash caused by poison ivy (Vogel 1970). Foster and Duke (1990) noted that a 1957 study by a physician found extracts of jewel weed effective in 2 to 3 days in treating 108 of 115 patients. Unhappily, I would have fallen into the minority for whom it was not effective. When I was an undergraduate in Kentucky, there were many times when I applied it to my skin. It never kept me from developing a severe poison ivy rash or relieved the itching.

The Cherokee, Meskwaki, Omaha, and Potawatomi relieved the rash caused by wood-nettle (*Laportea canadensis*) with juice of jewel weed (Smith 1933, Vogel 1970, Hamel and Chiltoskey 1975, Moerman 1998). The Cherokee, Iroquois, Mohegan, Nanticoke, Ojibwa, Omaha, Penobscot, and Shinnecock treated burns, cuts, hives, liver spots, measles, raw or sore eyelids, and rashes with various preparations made from *Impatiens* (King 1984, Moerman 1998). The Cherokee included it as one of the plants in their "Green Corn" medicine, and used it to help ease childbirth pain (Hamel and Chiltoskey 1975). A related analgesic use by the Ojibwa was to relieve headache (Moerman 1998). Whole-plant infusions were used by the Cherokee and Potawatomi to treat chest colds and stomach problems (Hocking 1997). The Iroquois used it as a diuretic for dropsy and to treat fever (Hocking 1997, Moerman 1998).

Hocking (1997) said that this species is emetic, but he may have confused it with the related *I. pallida* (Porcher 1863). That species is not known in Florida, but it has a variety of uses, many similar to *I. capensis*.

The plant provided a yellow-orange dye for the Menomini, Ojibwa, and Potawatomi (Smith 1933, King 1984, Hocking 1997, Moerman 1998).

### *Ipomoea*

(Greek *ips*, *ipos*, worm or bindweed, *homios*, *hoimios*, resembling, referring to the twining habit)

*Ipomoea imperati* (possibly from Latin *imperatus*, ruler or emperor)

*batatilla* (little potato, Dominican Republic)

beach morning glory (Florida)

*bejuco de cadena* (chain vine, Venezuela)

*bejuco de costa* (coast vine, Puerto Rico); *bejuco de puerco de costa* (coastal pig vine, Puerto Rico); *boniato de playa* (beach sweet potato, Cuba; *boniato* is a Taino word, perhaps originally applied as now to the

white-fleshed, pinkskinned *I. batatas*, and extended to other members of the family for comparison)

*bejuco de las tortugas* (turtle vine, Guerrero)

*liane manger cochon* (hog-food vine, Haiti) *palate lan mer [marron]* ([wild] beach potato, Haiti)

A strong decoction of the root has been used against dysentery, and an infusion of the stem has been taken for venereal diseases (Pittier 1926).

***Ipomoea indica*** (from India)

*aguinaldo morado [rosado]* (purple [rosy] gift, Cuba)

*bejuco de gloria* (glory vine, Puerto Rico)

blue dawn flower (Florida)

*bois patate marron* (wild potato bush, Haiti); *palate marron* (wild potato, Haiti); *patate sauvage* (wild potato, Haiti)

*campanilla* (little bell, Honduras); *campanitas* (little bells, Dominican Republic)

*estrella vespertina* (morning star, Dominican Republic)

*gloria de la mañana* (Belize); [purple] morning glory (Florida, Bahamas)

*liane manger cochon* (hog-food vine, Haiti); *mange cochon* (hog food, Haiti)

*liane purgative* (purgative vine, Haiti); *liane purgative a Bauduit* (Bauduit's purgative vine, French Antilles)

*quiebra-platos* (plate breaker, Oaxaca, Veracruz)

*quilamula* (Quiché, Guatemala)

*rue purgante* (purgative rue, Haiti)

*sayiin* (Quiché, Guatemala)

*soyotquilit* (*soyot* =?, *quilitl*, greens or edible herb, Náhuatl)

Roots of this species are purgative as is the milky sap (Liogier 1974, Morton 1981). A decoction of the leaves is used against sores and ulcers (Liogier 1974)

***Ipomoea pandmata*** (fiddle or violin shaped, meaning the leaves)

High John the Conqueror (see also *Triadenum*)

man-root

man-of-the-earth

wild jalap (applied in the late 1700s although "jalap" is a Mexican species; more confusingly, "jalap" has been applied to *Podophyllum*, which see)

wild potato [wild-potato] [vine]

William Bartram wrote, "The dissolvent and diuretant powers of the root of the convolvulus panduratus [*Ipomoea pandurata*] so much esteemed as a remedy for nephritic complaints, were discovered by the Indians to the inhabitants of Carolina" (Bartram in Swanton 1928a). Missionary George Henry Loskiel recorded in 1794 that

“convolvulus jalappa” grew in abundance in “Indian country, and is prescribed as a purgative. In the rheumatism of the legs they roast the roots, then slit and apply them to the soles of the feet as hot as the patient can bear” (Loskiel in Vogel 1970).

Yanovsky (1936) and a number of others said the roots were considered famine food by indigenous tribes. It is pertinent that neither Gilmore (1919) nor Hedrick (1919) listed the species. The resins (~5%) in the roots make them less than palatable and digestible. They were, however, used as a mild purgative, to expel gravel, and to treat malaria (Hocking 1997). Roots were used by Carolina tribes to treat kidney trouble, rheumatism, and purgative (Vogel 1970). Part of the confusion about edibility seems to have been misidentification of the “Potato Clan” among some eastern tribes with this plant. Their symbol was actually *Apios* (which see).

The mystical shops are selling what appears to be roots of this North American species under the name *I. jalapa* and High John the Conqueror (cf. Yronwode 1999). They tout the root as an aphrodisiac, mirroring its older names man-root and man-of-the-earth.

***Ipomoea pes-caprae*** (goat’s foot)

*batatilla* (little potato, Dominican Republic); *boniato deplaya* (beach sweet potato, Cuba, Puerto Rico)

bay hops [winders] (Florida, Bahamas); *bejuco de mar* (sea vine, Veracruz); *bejuco de playa* (beach vine, Mesoamerica)

*bejuco de la tortuga* (turtle vine, Mesoamerica)

cowslip (Belize)

goat’s foot (USA); *pata de cabra* (goat’s foot, Veracruz)

*liane manger cochon* (hog-food vine, Haiti)

*patate bord de la mer* (seaside potato, French Antilles); *patate lan mer [marron]* ([wild] beach potato, Haiti)

railroad vine (USA)

*riñonina* (little kidney, Mesoamerica)

Used against arthritic pain and internal upset, also as a purgative and diuretic, and to lower blood pressure (Roig 1945, Vasquez and Jácome 1997). Elsewhere it has been used against “weakness in women,” for bathing sores and wounds, as a febrifuge and emollient, and to treat animal stings and bites (Duke 1972, Morton 1981). Recent studies indicate that it contains compounds as effective as Benadryl® (Pongprayoon 1991, Pongprayoon et al. 1991, 1992). In Belize, the vines are used to make a dye (Balick et al. 2000)

***Ipomoea sagittata*** (having arrowhead-shaped leaves)

glades [marsh, salt-marsh] morning glory (Florida)

*l’herbe à congo* (Congo herb, but *congo* here meaning the water moccasin, *Agkistrodon piscivorous*, Houma, Louisiana French)

snake grass

*wahoʔe* *entayhe* [waaho(th)e *entahe*]  
*wahoʔe,* (water moccasin, *entayhe*, bed, Mikasuki)

The Houma used it to purify the blood and as a remedy for snakebite (Speck 1941). The Seminoles use the same name for this, *Mikania scandens* and *Ludwigia*. The plant is used to treat Snake Sickness (Bennett 1997).

***Ipomoea violacea*** (purple, a misnomer through confusion)  
*aguinaldo blanco de costa* (white coastal gift, Cuba)  
 beach [coast] moonvine [moon vine, moon-vine] (Florida, Puerto Rico, English Antilles)  
*bejuco de luna* (moon vine, Puerto Rico); *flor de luna* (moon flower, Puerto Rico)  
*bejuco de vaca* (cow vine, Puerto Rico)  
*ferrocarril* (railroad)  
*jabilla* (name usually used for *Hura crepitans*, Taino, Cuba)

The plant is used against skin and liver problems and considered emollient and vulnerary (Roig 1945).

### ***Ipomoea*: Moonvines**

(See preceding entry for etymology)

Shortly after 1913, the Lake Okeechobee American Legion developed a cheer for a West Palm Beach parade:

Custard Apple, Moonvine, Catfish and Moonshine!  
 Ever-glades Post 20! Whoopee! Muck Rats!

That pretty well summed up the abundance of moonvine (*Ipomoea alba*) in southern Florida at the time (along with a few other prominent items). Moonvine formerly blanketed the canopy of a pond apple forest that stretched for 32,000 acres along the southern edge of Lake Okeechobee (Will 1964a). This forest, and the moonvines covering it, was totally destroyed and replaced by agriculture. A belt of trees and vines 50 miles long and 2 or more miles wide was eliminated in less than a decade (Small 1929). Although moonvines are not as common in Florida

***Ipomoea.*** *Ipomoea alba.* Drawing by Regina O. Hughes. Courtesy of the United States Department of Agriculture.

as they once were, they are still abundant in some places.

Moonvines, also called moonflowers in English and *flor de luna* (moon flower, Veracruz, Tabasco) in Spanish, have fascinated people since the first Europeans arrived in the New World. The flowers open in the evening, they are strongly scented, and they attract large nocturnal sphinx moths (Sphingidae). That combination of traits, plus some others, enticed the Spanish to carry the seeds back to Europe and then to the rest of the world within the first few years after 1492. The plants became pantropical so quickly that until recently there remained a cloud of confusion about their origin. Most people, from at least the 1750s to the present, thought that the first mention of the moonvine was by H.A. Rheede in his list of plants cultivated in Malabar, India, in the 1680s. However, it appears that the first record was made by an early Spanish historian. Shortly after his arrival in Panama in 1514, Gonzalo Fernandez de Oviedo wrote about *the flor de la Y* that he found in Cuba (Oviedo [1526] 1969). All students of that island have equated that account with *I. alba*, and Oviedo's brief description fits.

The origin of the Taino word "Y" for these plants has been a mystery ever since. It may be a comparatively simple matter of related words (cognates) and partial misunderstanding on the part of the Spanish.

We know from Columbus's account that the Taino people of Hispaniola called *I. batatas* (sweet potato) *ajé* [also spelled *hage*, *age*, *aje*, *axe*, *ase*] (Jane and Skelton 1960, Sauer 1969). The Taino spoke a language related to the Arawakan people of northern South America. The Arawaks call the sweet potato *haliti*, and their relatives the Guajiro say *haisi*. Taino, Arawak, and Guajiro words are cognate with *á:hi* (Mikasuki), *ahe* (Choctaw), *vhh [aha]* (Creek), and even *nuna* (Cherokee). Through simple misunderstanding or poor transcription, the Taino word would be changed to “é” or “y” by Spanish-speaking listeners in the 16th century. So, the name Oviedo left behind for the moonflower, *flor de la Y*, may be translated “flower of the *ajé* or morning glory,” or, more exactly, the “root with flowers.”

Surely, the Cuban name *jabilla* is related to “Y.” *Jabilla* (from *jabí*) too is probably based on the same root as Taino *hage* and Arawak *haliti*. This Cuban name is applied to *I. violacea*, a species that resembles *I. alba*. In both Spanish (*aguinaldo blanco de costa*, white coastal gift) and English (coast moonvine) the *jabilla* is considered the “coastal” moonvine because it is found on beaches and in mangroves. Could *mash* (Chiapas) be another cognate?

Other common names are easier to understand. In Hispaniola, moonvine is rendered *estrella vespertina* (evening star), and in Yucatán *oration* (prayer). Colombians say it is *galán de noche* (gallant at night). French Antilles people say *belle de nuit* (beauty of the night). Early settlers in Florida called it “nightbelle” (Williams [1837] 1962). This fascination with the evening flowers spilled over into Europe and caused Swiss botanist J.D.Choisy (1799–1859) to separate the species out into the genus *Calonyction* (beautiful at night, Greek) in 1833. Yet, the similarities in shape and time of flowering between moonvine and some other species in the family do not necessarily indicate relationships. More often, the flower shape reflects convergence onto a pollination type from several different lineages.

Hondurans prefer to call the moonvine *pañal de niño* (child's diaper), while people in El Salvador call it *garza* (egret). That Salvadoran name is probably a corruption of indigenous names for the plants, including *gamuza* (Chiapas), *huamol* (Chiapas), and *guamol* (Chiapas). Those words might be linguistically related to *amule* (variant of Nahuatl *amole*, soap, Oaxaca), or they may have some other relationship.

Moonvines are also called *bejuco de tabaco* (tobacco vine) in El Salvador, because stems were used to tie up tobacco leaves to dry (Standley 1920–1926). In Mayan-speaking areas from Chiapas to Yucatán, the climber is *nacta* (Lacandon), *naxh*, *huchuk* (hiccup), *huchuk ts'aan* (hiccup vine), *xpeten* (an island in water or of vegetation usually with a permanent pond within), *piroreta* (spiral), and *sutup* [*suput*, *xutu*, *xutub*, *zutub*] (something that turns or forms a spiral). Even though three of the translations suggest only descriptive terms regarding the twining or climbing life-form, their existence shows that people took note of the plants. Often when any people have a name for a plant, they have a use for it, whether or not they share that information. Other Maya call the plants *haapolin* (*ha*, water, *polin*, origin, or found near water, Yucatan). They know that where they see a vine, there will be a place to get water.

Venezuelans and Mexicans call these vines *nigua* (chigger). *Nigua* is another Taino word that was spread widely outside Hispaniola by the Spanish. Was moonvine really used against chiggers, as was chiggery grape (*Tournefortia hirsutissima*)? There are numerous uses for the plants, but nothing has been found that substantiates that use.

Moreover, moonvine and several unrelated plants are called *nigua*. Perhaps *nigua* is a general name that refers to some physical trait resembling chiggers.

In Puerto Rico and Oaxaca, Mexico, the twiners are *bejuco de vaca* (cow vine), and *bejuco de puerco* (pig vine), because they are fed to those animals as fodder. There are reports of the immature seeds being eaten in India, and the plant has had the reputation there as a snakebite remedy since at least the 1600s (Watt 1898, Standley 1920–1926).

There are several other recorded applications, including use as a febrifuge, to stop hair loss and dandruff, as a laxative, and to expel gas (Liogier 1974). Some Mayans suggest that it “diverts hunger when tied around body.” Oviedo ([1526] 1969) was the first to note the plant’s laxative aspects, and that is likely why the Spanish took moonvine and many other American plants around the world. People in Oviedo’s time were convinced that all human maladies came from being “poisoned” by material in their colons. Laxatives were the medical panaceas.

There are enough chemicals in the vine to have real impact on several of the problems it is used to treat. Moonvines contain calystegines, resins, indolizinic alkaloids, ipomine, and ipalbidine (hexahydroindolizine alkaloid) (Gourley 1969, Dawidar et al. 1977, Ikhiri et al. 1987, Schimming et al. 1998). The calystegines are poisons (=medicine, in small doses), the resins are laxative, and alkaloids have a number of effects on human physiology.

Milky juice from moonvine stems has a long pre-European history in Mesoamerica of being used to coagulate latex from the *arbol de caucho* (rubber tree, *Castilla*, Moraceae) (Standley 1920–1926). The vine is the *bejuco de cuajar hule* (vine for coagulating *Castilla*, Oaxaca), or simply *cuaja leche* (coagulate milk, Oaxaca). *Castilla* was an important rubber source for the Mayans who used it to make balls for their *game pelota*, among other things (Hosier et al. 1999). The Aztecs also adopted rubber use, and considered the sap the tree’s “blood.” Balls from this *caucho* were so valuable to the Aztecs that they paid their taxes with them.

Although humans have carried moonvine with them, it also travels well without them. The seeds are dispersed by water, and that is one of the reasons it was so common on Lake Okeechobee at the beginning of the 1900s. The seeds float so well that they arrive regularly on the coasts of Britain, Ireland, and presumably Norway (Gunn and Dennis 1976). Since the closest point of origin for those drift-seeds is the Cape Canaveral area of eastern Florida, they have a long seawater journey—at least 6759 km (4200 miles). Drift-seed enthusiasts in those areas report that they arrive literally by the thousands. One person reports that they come in “numbers beyond imagining.” Incredibly, some small percentage is still alive when they arrive on the southwestern coast of England. A colleague there has been able to germinate them for illustrations for a book he wrote on the species found on British coasts (Nelson 2000).

One of the first things that I did when I first arrived in Florida was to survey the southeastern coastal area for morning glories. The most abundant species in wetlands was the moonvine. I found a spot on the edge of the Everglades where a vine sprawled over the shrubs and trees near a swamp. One evening I set up a camera with a flash on a tripod and focused on an unopened bud. Promptly at 7:00 P.M., the flower began to open and shed its musky fragrance into the mosquito-filled dusk. Within minutes after it opened a large tomato horn worm sphinx (*Manduca sexta*) arrived and probed the flower with its strawlike proboscis. I stepped over and snapped the picture. It seemed like the easiest

thing in the world, and I anticipated many more photographs like it. But, 30 years later, I had added only one. Moths and moonflowers are unpredictable subjects.

### ***Iresine*: Bloodleaf**

(From Greek from *eiresione*, *eiros*, wool)

My students often found a particular herb reaching to about a meter tall scattered through dry sites. When growing in those sites, the leaves and stems are often tinged with red, leading to the common name

***Iresine diffusa*. From Britton and Brown 1896.**

bloodleaf (Florida). Other names that are related to the color of the plants include *camarón* (shrimp, Costa Rica) and red dandelion.

The Latin name for these members of the Amaranthaceae is *Iresine diffusa*, although some of the older literature uses the name *I. celosia*. The opposite leaves, swollen nodes, and red coloring made the plants comparatively easy for students to identify. However, sometimes when wading through swamps such as Fakahatchee Strand State Preserve, we would find larger herbs with more delicate leaves, longer internodes, and more open inflorescences. There was never a trace of red on those plants. Students rarely saw the similarities and usually tried to make it something more than an etiolated form of the more familiar variation of bloodleaf.

A more constant trait of these herbs is the flowering and fruiting clusters, which are always “cottony.” Indeed, it was that trait that led to the name *Iresine*. That genus was named by Patrick Browne in his book, *The Civil and Natural History of Jamaica*, published in 1756. Some have proposed that the genus name came from Greek *iris*, a rainbow, and *isnos*, ribs of the leaves, an allusion to the color on the leaves, but that does not seem to be the case. If Linnaeus had named the genus, it would have been more likely that he used a dual meaning name, as he loved to make such commentaries.

The cottony aspect of the plants has been noted by people in the Caribbean and Central America. In those places, the herbs are known as *adorno de niño* (child’s adornment, Guatemala), *algodoncillo* (little cotton, Central America), *barba de viejo* (old man’s beard, Central America), and *herbe coton* (cotton herb, Guadeloupe, Martinique)

to indicate that aspect. Probably the name *zacxiu* [*zactezxiu*, *zakyezxiu*] (*sak*, white, *xiw*, herb, Maya, Yucatan) makes the same suggestion. Since the related species *I. calea* of Mexico and Costa Rica is called *cola de cabra* or *cola de chivo* (goat's tail), perhaps *chivito* (little goat, Central America) applied to *I. diffusa* makes the same allusion. All the references to goats must be noting the white cottony appearance. Of course, the plants are also grazed by livestock, and that is probably also inherent in those common names.

The meaning is not clear, but the same comments may be indicated by some other names. These names include *hierba de la plata* (silver herb, Central America), *plumaria* (little feather, Colombia), and *velo de princessa* (princess's veil, Guatemala). They are also called *velo de novia del monte* (wild lady's veil, Puerto Rico). That seems to be a comparison with *velo de novia*, which is *Parana paniculata* (Convolvulaceae). Both the Amaranth and the morning glory have a profusion of small white flowers, and that may be the reason for these and the other common names.

When the wind blows through the plants, they dance. That "dancing" must be related to the common name juba bush [jubba bush, juba] (Jamaica). *Juba* is a dance that originally came with slaves from western Africa to the Caribbean in the 1500s, and to the United States in the 1600s (Major 1994). In their new homeland, these people continued their secular and religious "step dances," and even accompanied them with drums called *yubá* or *juba*. Originally, the American dance was a competitive event where opponents would try to outdo one another in feats of skill, even balancing a cup of water on their heads. As these African dances encountered Irish jig and clog dances, they incorporated elements from them. Eventually, the dances changed so much they became known as "tap dancing," and they were made famous by the early 1800s by people such as William Henry Lane (nicknamed "Master Juba"), born in 1825.

Surely, *felicidad* (happiness, Puerto Rico) also refers to the "dancing" plants. Perhaps similar movements lead to *taba de gueguech* (*taba*, one who directs an Indian dance, Zapotec, Oaxaca, El Salvador). *Yerba de cabeko* (moving herb, Belize) is similar.

The name *taba de guëguëch* is odd, however, in that the word *taba* also refers to a foot bone. The bone reference seems to be related to the names *canillita de zanate* (grackle's long bones, Central America), *coyontura* (bone joint, El Salvador), *coyontura de zanate* (grackle's [bone] joint, Central America), and *coyontura de pollo* (chicken's [bone] joint, El Salvador). These five names may actually be comments on the swollen nodes of the stems, which somewhat resemble joints. Indeed, they may be names that indicate an application of the Doctrine of Signatures. That philosophy holds that, if a plant resembles a body part, it is good to treat maladies of that part. If that is the case, none of the medical uses I have found reflects that.

There are several medical applications of *I. diffusa*. People from the Catawba who live along the coastal Carolinas and Georgia to Colombia in South America have used the plants to obtain relief from coughs. The Catawba used a syrup of leaves and stems against whooping cough (Speck 1937). In Colombia, the plants are sold by vendors to use in a decoction to stop coughs (Pérez-Arbelaez 1978). That use is certainly reflected in the name *l'herbe à croupe* (whooping cough grass, Houma, Louisiana), and probably by bitter weed (USA). The plant is also used in Colombia to relieve pain in the side associated with violent coughing.

Related medical applications are to treat colds and edema in Jamaica. When a decoction is mixed with *Desmodium* and *Borreria laevis*, the tea serves as a diuretic and

purgative used in Jamaica against dropsy and gonorrhea (Ayensu 1981, Morton 1981). *Hierba de orín* (urine herb, Veracruz) surely denotes the diuretic nature. A slight variant is used in Venezuela, where the plant is reduced to ashes, lemon or lime is added, and the mixture taken as a purgative. That same mixture might be used to treat bowel pain. In Cuba, a decoction is used for stomach ailments (Uphof 1968), including colic. This drink is given to women in childbirth as a tea mixed with *Piper nigrinodum*, salt, and a few drops of whiskey. In Guatemala, the juice has been used to treat erysipelas (Standley and Steyermark 1946).

Several of the common names may be related to medicinal uses. For example, the herb is *chancanil* (*chan*, small, *kanil*, roots, Queech', Guatemala), *mosquito* (Guatemala), *pie de paloma* (dove foot, Guatemala), *siete pellejos* (seven skins, El Salvador), *tabudo* (a

*?cueitl*,

forbidden [*tabú*] plant, Guatemala), and *tlancuaya* (*tlán*, near, skirt, Náhuatl, Veracruz). The *pie de paloma* may be a comment that doves consume and spread the seeds. Perhaps they are called *siete pellejos* because of their colors.

Although the genus *Amaranthus* is reasonably well studied, not many other genera are well known chemically. No chemical studies seem to have been made of *L. diffusa*; however, the related *I. herbstii* has been examined. That originally South American species, called beef plant, beefsteak plant, *chorcha de gallo* (rooster cork), and *gésier poule* (chicken gizzard), is known to have antibiotic activity (Wong 1976). Moreover, studies of the effects of aqueous extract from *I. herbstii* on the central nervous system indicate its possible use in catalepsy and nociception (DeFeo et al. 1996). Otherwise, the species shows promise as a source of betacyanins (Cai et al. 2001), of potential use in food coloring.

*Iresine* is a genus native to the tropical and temperate regions of the Americas and Australia with about 80 species (Mabberley 1997). Most species grow in dry, open areas in their native lands. *Iresine herbstii* and *I. lindenii* (blood leaf) are the most widely cultivated species and are grown for their red leaves.

*Iresine diffusa* is among the most common weeds in disturbed sites throughout its range from North Carolina to Louisiana and Texas, the Bahamas, the West Indies, from Sonora and Chihuahua in Mexico to Panama, and south to Peru and Argentina. Probably, that is why they are called new-burn weed (Bahamas). When a site is disturbed by fires, hurricanes, or something that moves the soils, these plants appear. The species is heliophylic and persists as long as there are openings and sunlight. They occur only where there are breaks in the canopy. There they can perch on cypress stumps, old logs, or other openings.

Also preferring open sunny sites dominated by grasses is the Juba Skipper (*Hesperia juba*), originally named by Samuel H. Scudder in the 1870s. Skippers are notorious for bouncing flight. No doubt Scudder saw the "dancing" butterfly and thought of the African dance then popular.

## *Iris*

(Greek for rainbow and the ancient name of the flower; also the Greek goddess of the rainbow and messenger of the gods, daughter of Thauas by the oceanid Electra)

flag (of obscure origin, but perhaps from Gaelic where the word means bulrushes prepared for weaving; in English by A.D. 1381); *flaede* (Middle Danish); *flaeg* (Danish); *flag* (Dutch)

*giaggiolo* (Italian)

iris (from Greek; Iris was the goddess who was the messenger of the gods, and was held to display as her sign or appear as a rainbow; in English by A.D. 1490); *iris* (French)

*lirio* (lily, Portuguese, Spanish)

*pakwiasko'ns* (water weed, Potawatomi); *sênipa'spwûn* (Prairie Potawatomi)

*Schwertlilie* (sword lily, German); *sverdlilje* (sword lily, Norwegian)

*seilistear* (Gaelic, for *I. pseudoacorus*)

### *Iris hexagona* (six angled)

Dixie iris ("Dixie" became a euphemistic name for the southern United States [the "South"] in 1859 after Daniel D. Emmett wrote the song *Dixie*, Florida)

*pasí:nácákí* (dwarf cat-tail, *pasí:nî*, cat-tail, Miksauki)

prairie iris (Florida)

*Iris virginica*. From Institute of Food and Agricultural Sciences.

***Iris verna*** (spring-flowering)  
dwarf [dwarf violet, violet] iris

***Iris virginica*** (of Virginia)  
*oko:willi paká:li* (*okí*, watery, *ilillá*, death, *paká:li*, flower, Koasati)  
Virginia iris

Linnaeus ([1753] 1957) knew 18 species of *Iris*, with 12 of them growing in Europe. The genus was well known to most Europeans and had acquired a variety of common names in different languages. When they arrived in the New World, Europeans found species new to them, and the genus now contains about 210 species, with 30 in Europe (Mabberley 1997).

Hogan (1978) found *Iris* pollen in her samples from the Glades site at Fort Center on Lake Okeechobee. These people had been using the plants for something, although it is not clear what that may have been. In 1919, Sheehan and Small were told that *Iris* was one of the plants given to Seminoles bitten by alligators (Small 1933, von Reis and Lipp 1982). Sturtevant's (1955) informants were not familiar with that application. Taylor (194) also found the Koasati using the plants. Given the widespread application of *Iris* as medicine (Moerman 1998), doubtless several species had historical use.

The Cherokee used the roots of *I. verna* or *I. virginica* in a compound medicinal salve for ulcers and took an infusion for liver and urinary problems (Hamel and Chiltoskey 1975). Creek considered *I. verna* a powerful cathartic (Swanton 1928a).

## ***Iva***

(Said to be named after the similarly fragranced mint, *Ajuga iva*; also Latin for the yew, *Taxus*)

***Iva. Iva annua*** . From Lamarck 1823.  
***Iva frutescens*** . From Britton and  
Brown 1898.

***Iva annua*** (living a single year; annual)  
careless weed

[annual] marsh elder [marshelder] (“marsh elder” in use by 1755 to indicate the genus *Iva*, “marsh” is a tract of low-lying land that has standing water most of the year; in use since about A.D. 725, from Old English *mersc*, *merisc*, akin to Dutch *mersch*, German *Marsch*, Danish *mark*; probably derived from Latin *mariscus*)

sump weed [sumpweed] (“sump” in use for a swamp, marsh, or morass since about A.D. 1425; related to Low German *sump*, *sumpf*, Middle Dutch *somp*, *sump*, Flemish *zompe*, and West Frisian *sompe*; akin to Greek *somphos*)

***Iva frutescens*** (shrubby)

bigleaf sumpweed (Florida)

high-water shrub (Florida)

horse brush (Florida)

marsh elder (Florida)

Linnaeus ([1753] 1957) created the genus *Iva* with two species, *I. annua* and *I. frutescens*. The former was based on Adrian van Royen’s list of plants cultivated in Leiden of 1740, his own *Hortus Uppsaliensis* of 1748, and his list of dissertations in *Nova plantarum genera* of 1751. He also cited a specimen given to him by A.L.de Jussieu. Both he and Royen had seen cultivated specimens of *I. frutescens*, and he had literature citations and herbarium specimens from other sources. There is nothing in the phrase names used before 1751 that would have been an inspiration for his using *Iva*, so he apparently took it from elsewhere.

All sources that I have seen waffle on the origin of the word *Iva*. Several authors say simply that it was the “old name of some medicinal plant” (e.g., Fernald 1950, Weber 1987). Gledhill (2002) added that it was used by Rufinus (Archbishop of Sorrento, 12th century) and “applied to various fragrant plants.” Others say the genus is patterned after *Ajuga iva* (Munz 1973, Correll and Correll 1982, Hickman 1993, Diggs et al. 1999). No one has clarified why the mint has that name.

What no one seems to have pointed out is that Latin *ívus* is the basis of *íva* in Spanish, and that both are names for *Taxus*. It would appear that Linnaeus used *Iva* to compare this composite with a mint that grows under *Taxus*.

*Iva*, a genus endemic to North America and the Caribbean, comprises 15 species (Mabberley 1997). Florida has 5 species, with at least *I. asperifolia* introduced from Mexico, and there are several others in the United States (Fernald 1950, Correll and Johnston 1970, Barkley 1986, Hickman 1993).

Two of the species in Florida have been used by people. *Iva annua* was not only used by historic indigenous tribes, but a form was also cultivated by eastern people for their large edible seeds (Gilmore 1931, Jackson 1960, Black, 1963, Asch and Asch 1978, Yarnell 1978, 1986, Smith 1992). Archaeological sites yielding the large-seeded forms of sump weed have been found in Arkansas, Illinois, Iowa, Kentucky, Mississippi, Missouri, North Carolina, and Tennessee. More have been found near the Missouri and Mississippi River confluence than elsewhere, but the cultivar was widespread. Although sumpweed seeds are known from archaeological sites dated at ca. 3500 B.C., those are within the

size of wild plants. Seeds increased in size from ca. 2000 B.C. to A.D. 1300, so most believe that people were cultivating them and selecting for that trait (Fritz 2000b).

Seeds were harvested by hand, and Asch and Asch (1978) have shown that a single person can obtain enough seeds in 1 hour to supply an adult's daily energy requirements. When taken from the plants the seeds are enclosed in a fibrous shell of the achene. Again, Asch and Asch (1978) suggest that these were boiled to weaken or split the achene. Once the fruits are dried, they can be winnowed to separate the shell from the seed. When they sampled the produce, they were pleasantly surprised at the nutty taste; all of the disagreeable odor of the fresh plant had been eliminated.

The seeds contain about 40% fat and 32% protein. While low in lysine, the seeds are high in thiamine, niacin, calcium, iron, and phosphorus. Calorie content is similar to the sunflower (*Helianthus*, which see). These extinct cultivars were displaced as food with the introduction of maize in the first millennium B.C. (Smith 1992). Only the wild forms remain.

Hocking (1997) said that sump weeds were used by several tribes to treat stomachache or cramps, and claimed to be contraceptive. Neither Vogel (1970) nor Moerman (1998) included the species, and the source of that information has not been located. Crites and Terry (1984) and Zardini (1992) mention sump weed in relation to other cultivated seeds.

Hocking (1997) also said that the bark of *I. frutescens* was used to reduce fever. No corroborating source has been located, but Bohlmann and Zdero (1979) found two eudesman derivatives in *I. annua*.

# J

## *Jacquinia*

(Linnaeus dedicated the genus to Austrian Nicolas Joseph von Jacquin, 1727–1817, professor of botany and chemistry in the Medical Faculty of the University of Vienna, and later rector of the University)

***Jacquinia keyensis*.** a. Flower bud. b. Flower, from above at early phase, c. Flower, longitudinally dissected, d. Flower, from above at later phase, e. Flower, longitudinally dissected at later phase, f. Anther, from back. g. Anther, from front, h. Floral diagram, i. Fruiting branch. *Drawn by Priscilia Fawcett.* From Correll and Correll 1982.

***Jacquinia keyensis*** (of the Florida Keys)  
 Joe-wood [Joe-bush] (Bahamas)  
 ironwood (Bahamas)

*Jacquinia* is a genus of 35 species in Central America and the Caribbean (Mabberley 1997). Fruits from several species are notoriously poisonous with rotenone and have been used to catch fish (Hocking 1997). Perhaps the most famous for that purpose was long called *J. barbasco*, although it is correctly *J. arborea*. The word *barbasco* (from Latin *verbasco*, mullein, *Verbascum*, Scrophulariaceae) now means “fish-poison.”

The Florida species is the source of cudjoe wood (Mabberley 1997). Presumably, it too contains the poisons in the fruits.

### *Juglans*

(Linnaeus created the name from a contraction of *Jovis glans*, the nut of Jupiter—although *glans* has an alternate meaning, which he no doubt intended)

### *Juglans nigra*. From Sargent 1905.

*cnò Fhrangach* (*cnò* nut, *Fhrangach*, French, Gaelic)

*gall-chnò* (foreign nut, Gaelic)

*noce* (Italian); *nogal* (Portuguese, Spanish; from Latin *nux*, through vulgar Latin *nucale*); *noyer* (French); *Walnussbaum* (walnut tree, German); *walnoot* (Dutch)

#### *Juglans nigra* (black)

*assenamins* (Strachey wrote this Powhatan word as *assunnomeindg* in [1612] 1953 and said that it was a walnut; however, because of comparisons with other Algonquian words Siebert (1975) thinks it belongs with *Carya alba*, which see; distinctions between “walnuts” and “hickory nuts” typically were not made until ca. 1810); *osamener* (Carolina Algonquians)

*baganak* (Potawatomi, for *J. cinerea*; akin to Menomini *paka:n*, see *Carya illinoiensis*); *paucauns* (Strachey used the word in [1612] 1953 under “walnuts”; see also “pecan” under *Carya illinoiensis*); *ptucquim* [*pdukquim*] (Delaware); *tuk-wi-má-nsi* (walnut tree, Delaware)

*chak* (*chak-hu*, walnut tree, Winnebago); *chan-sapa* (*chan*, wood, *sapa*, black, Teton)

*haahi* (Alabama); *hahe* (Choctaw); *há:hi* (Koasati); *hayi* [*hayyi*, *hasyi*] (Chickasaw)

*hma* [*gma*] (Dakota)

*noyer* (Quebec)

*ochatapaski* (*ocha*, hickory, *tapaski*, fine textured, Alabama)

*osôchqua* (Onondaga)

*poho'n-ä* [*po-ho-na*, *poñ-hoñ-á-daw*, *poñ-hoñ-aigaw*] (the word in the name, *po-ho-na*, refers to a former tribal custom of the husband's right to cut off a piece of his wife's nose if he finds she has been unfaithful, Kiowa)

*sahtaku* (Pawnee)

*sedi* [*se:-di*] (Cherokee)

*ta'-ge* [*sha-e*] (Osage); *tdage* (*tdage-hi*, walnut tree, Omaha-Ponca)

*uksak* [*okesok*] (Choctaw)

*vhah'wv-enlókce* (Muskogee)

[black, eastern black walnut] walnut (foreign nut, to distinguish it from the hazel nut, *Corylus* derived from Anglo-Saxon *wealh*, Welsh, foreign, or alien, the second element is from Latin *nux*, nut)

*warn'* [*wararu'-*] (walnut, Catawba)

*yegg* (Atakapa)

My introduction to the black walnut occurred when I was a small boy. When my great-uncle learned that I was bothered with ringworm on my posterior, he vowed he could cure it very simply. All other remedies had failed my parents, and they agreed. I waited and watched with considerable apprehension while he walked across the clean-swept yard, hurrying the chickens out of the way, and picked up a green walnut fruit with the husk remaining. He broke the husk open, and ordered me to drop my pants. After I complied, he smeared the infected area with the dark juice from the walnut husk. Once it dried, he allowed me to put my pants back on. Within a week, the ringworm was gone. I gained new respect for my greatuncle and the black walnut. Many years later, I learned that he had applied a remedy that dated to the classical Greeks and Romans, perhaps earlier in the Americas (see also Murphee 1965).

Although the history of *Juglans* is much younger in Europe than in the Americas, Europeans were already familiar with walnuts when they arrived in the New World. *Juglans regia* was native as far west as the Balkan peninsula in Greece, Crete, Romania, Turkey, and Persia, but it had been introduced into Italy by 116 B.C. (Hedrick 1919). The Romans extended the cultivation of walnuts through ancient Gaul (France). By 1542, Leonard Fuchs said the walnut was cultivated throughout Germany, where it was called *Welchnusz* (Welsh nut), and the Dutch said *nootboom* (nut tree). The Italians were already saying *noce*, the French *noyer*, and the Spanish *nogal* (Meyer et al. 1999). When *Juglans* finally reached England, it first was called "Wealth nut" or "Gaul nut," and this evolved into "walnut" (Rosengarten 1984).

Records of hickories (*Garya*) and walnuts (*Juglans*) are difficult to sort out through the 1700s because they were lumped under *Juglans*. It was not until 1818 when Thomas Nuttall separated *Garya* that records became clear. Chroniclers of the de Soto expedition reported "walnuts" near modern Gainesville (Swanton 1939), but these were hickories (Wunderlin and Hanson 2002).

Harriot ([1590] 1972) wrote: "There are two kindes of Walnuts, and of them infinit store: In many places where very great woods for many miles together the third part of trees are walnuttrees. The one kind is of the same taste and forme or little differing from ours of England, but that they are harder and thicker shelled: The other is greater and hath

a verie ragged and hard shell: but the kernell great, verie oylic and sweete. Besides their eating of them after our ordinarie maner, they breake them with stones and pound them in morters with water to make a milk which they vse to put into some sorts of their spoonmeate; also among their sodde wheat [maize], pease, beans and pompions which maketh them haue a farre more pleasant taste.” The first kind is a *Carya*; the second is the walnut.

Bartram ([1791] 1958) recorded eight species of *Juglans*. The true walnut (*J. nigra*) was among them, as well as the pecan, but some he called “*Juglans hickory*.” Michaux did the same in his notes and herbarium, recognizing both *J. nigra* and “*Juglans hickory*,” but he listed only the walnut in his *Flora* of 1803 (Taylor and Norman 2002).

Throughout its range, people used black walnuts for food; Yanovsky (1936) listed use in the north—Minnesota, Nebraska, New York, North Dakota, South Dakota, and Wisconsin. The Cherokee mixed the nuts with hominy (*newada*) and beans into porridge much as did the Carolina Algonquians described by Harriot ([1590] 1972). The Cherokee also saved the dried nuts for later use (Hamel and Chiltoskey 1975). The Comanche ate fresh nuts and stored others for winter use (Moerman 1998). The Dakota, Omaha, Osage, Pawnee, Ponca, and Winnebago ate the seeds from the nuts directly, or made them into soup (Hunter [1823] 1973, Gilmore 1919). The *tdage* of the Omaha-Ponca is in their story of the “*Ishtinike* and the Four Creators,” indicating the reverence in which they held the trees and their antiquity of use. The Meskwaki ate nuts, as did their neighbors (Moerman 1998).

The most-detailed records of food come from the Iroquois of New England. These people boiled the fresh nut meats and drank the liquid. Fresh seeds were mixed with cornmeal to make a bread, which might also include beans and berries. Similarly, seeds were included in corn pudding, corn soup, hominy, and with mashed potatoes after Europeans introduced that South American plant. Oil was extracted from the nuts by boiling and used as a condiment on cornbread, corn pudding, and mush by the False Face Society (Moerman 1998).

Walnut trees also provided other materials. The Cherokee pounded walnut bark and put it into small streams to catch fish (Mooney 1885–1886). The Iroquois mixed nut meat oil with bear grease as a mosquito repellent and used the inner bark fiber to weave burden straps (Whitford 1941, Moerman 1998).

Black or brown dyes were made from the roots, bark, and fruit husks. Leaves produced a green dye. These dyes were made by the Cherokee, Choctaw, Dakota, Kiowa, Meskwaki, Ojibwa, Omaha, Pawnee, Ponca, and Winnebago (Bushnell 1909, 1917, Gilmore 1919, Moerman 1998). Traditional Cherokee basket makers still use these dyes to stain their wares. One of these, a prized item I got in the Qualla Coop store in Cherokee, North Carolina, in the 1970s, is made from hickory splints.

Walnut has been one of the most desirable woods in the eastern United States, to the point that “poachers” sometimes steal trees from yards. Rosengarten (1984) recorded that a single tree might be worth \$30,000 for its wood. Walnut wood is used in making superior furniture, cabinets, veneers, caskets, coffins, posts, railroad ties, and fuel (Vines 1977). Walnut was prized for making gunstocks during the Civil War and World War I, and is still considered one of the best woods for that purpose (Rosengarten 1984).

Many people used walnuts as medicine. The only record among Muskogean people seems to have been with the Houma. They used an infusion of nutshells to relieve the

itch, and a decoction of leaves to lower blood pressure (Speck 1941). Other groups used the inner bark in a tea as an emetic and laxative; the bark was chewed for toothache or made into an infusion to stop diarrhea and expel worms; and fruit husks treated ringworm, colic, and were poulticed on headaches, sores, and inflammations (Ford 1975, Foster and Duke 1990, Moerman 1998). Use is known among the Cherokee, Comanche, Delaware, Houma, Iroquois, Kiowa, Meskwaki, and Rappahannock (Moerman 1998).

Juglone is among the active compounds in walnuts. It is antiseptic, antifungal, and herbicidal (Lewis and Elvin-Lewis 1977, Foster and Duke 1990). Tannins are also abundant, and are effective antibiotics in addition to contributing to the dyes. Black walnut also contains lectins and ellagic acid, and thus is somewhat active against tumors (Lewis and Elvin-Lewis 1977).

The Delaware spread leaves to get rid of fleas (Moerman 1998). The Choctaws also scattered *okesok* leaves to drive fleas away (Bushnell 1909). Because of the smell of the leaves, and the tendency of fleas to congregate where people and their animals live, that probably worked.

### *Juncus*

(From Latin *iuncus*, for a rush, derived from *iugere*, to tie or bind, from the use of stems for that purpose; akin to Akkadian *unqu*, *uqu*, ring, Greek *onkos*, hook)

***Juncus effusus*.** From Institute of Food and Agricultural Sciences.

*Binse* (German)

*jonc* (from Latin *juncus*, French); *junco* (Spanish)

rush (of uncertain etymology, but perhaps from Germanic words, from Old English *rise* [*rix*, *rise*, *rix*], Middle Dutch *risch*, and Middle Low German *risch(e)* [*rysse*, *risk*, *ryse*] dating to about A.D. 725)  
*siv* (Norwegian)

***Juncus bufonius*** (of toads, from its occurrence in damp places)  
[common, toad] rush

***Juncus effusus*** (loosely spreading)

*albatá incassi* (*albatá*, alligator, *in*, its, *cassí*, corn, Koasati)

[common, rice] bullrush (“bullrush” is of uncertain etymology; from Middle English *bulrysche* or *bolroysche*, from about A.D. 1440; the term is also applied to *Scirpus* and *Typha*, which see)

*cakekesqus* (Strachey in [1612] 1953 said this was the Powhatan word for “rushes”)

[common, Japanese mat, mat, soft, *tatami*] rush

Many of the Cyperaceae and Juncaceae have flexible, tough stems and have been called similar terms by people throughout Europe and North America. *Juncus* has been used in Egypt for matting since the Neolithic (Mabberley 1997). Leaves until recently were still used in Scotland for thatching roofs, and may still be seen in historical replicas of old houses. The genus contains about 300 species and is nearly cosmopolitan (Mabberley 1997). Europe has 53 species and Kartesz (1993) lists more than 100 for North America. In addition to these 2, Moerman (1998) listed 12 others that were used by North American tribes.

Perhaps it was one of the *Juncus* that was used by people on the Great Plains of Arkansas to cover their houses when they were visited by the de Soto expedition in 1541. Ruiz Hernández de Biedma then wrote: “[W]e came to some collections of huts, covered with rush sewed together. When the owner of one moves away, he will roll up the entire covering, and carry it, the wife taking the frame of poles over which it is stretched; these they take down and put up so readily, that though they should move anew every hour, they conveniently enough carry their houses on their backs” (Biedma in Swanton 1939). Biedma was critical of them because they had no interest in growing plants for food, but he failed to point out that there were so many buffalo ranging through the area that they would have been unable to protect their crops from them.

The Cherokee used *J. effusus* to bind oak leaves around dough before it was cooked (Hamel and Chiltoskey 1975). The Ojibwa used rushes for weaving mats, bags, and pouches (King 1984, Moerman 1998). All the other records are from western tribes, including the Cahuilla, Hesquiat, Karok, Mendocino, Porno, Snuqualmie, Tolowa, and Yurok. All these groups used *Juncus* leaves for tying and weaving.

Porcher (1863) noted that *J. effusus* was “cultivated in Japan for making floor mats, chair bottoms, etc. It is sometimes employed in South Carolina for similar purposes. The pith, when dried and oiled, will serve as a wick.” His reference to the Japanese using the rushes is for making *tatami* mats.

There are even records of the Mendocino, Okanagan-Coville, and Snuqualmie either eating the plants or feeding them to their animals (Moerman 1998). The introduced Old World horse and cow might eat the plants, but they hardly seem edible for humans.

Only the Cherokee and Iroquois are noted as having used *Juncus* for medicine in the eastern United States. The Iroquois used a decoction of *J. bufonius* as an emetic; runners drank it to prepare themselves to race (Moerman 1998). *Juncus effusus* was also considered an emetic among the Cherokee. Other uses included an infusion given to babies to prevent lameness and a wash to strengthen them. The Karok in California regarded the rush as sacred and their shaman burned it as an offering while praying.

Settlers and later Americans considered *J. bufonius* diuretic and cathartic (Hocking 1997). *Juncus effusus* was also used as a mild diuretic, to expel kidney stones (lithiasis), and for urination difficulties (strangury). It was also used as a cathartic (Hocking 1997). Porcher (1863) noted for *J. effusus* that “A decoction of the plant is said to be diuretic.”

Hocking (1997) found that the roots of *J. effusus* contain tannin and a tripeptide.

### *Juniperus*

(The classical name, from Latin *ieniperu*, *gigiperus*, names used by Virgil, 70–19 B.C., and Pliny, A.D. 23–79)

***Juniperus communis*** (Latin *communis*, common; Circumboreal, but not in Florida)

*aiteonn [aiteann]* (Gaelic; badge of the Highland clans Athole, Gunn, MacLeod, Murray, and Ross)

*faile de dh'iubhar beinne* (bath of the juice of the juniper, a favored treatment for headache, Gaelic)

*ga'gawan'dagisid* (deceptive, Ojibwa)

*iubhar-chreige* (*iubhar*, yew, *chreige*, craig or rock, Gaelic)

juniper (English by the 1400s) *enebro* (Spanish in 1542); *einer* (Norwegian); *geneure [ieneuve]* (French in 1542); *genever* (Dutch in 1542); *genève [genèvier]* (French); *ginepro* (Italian in 1542); *zimbro* (Portuguese)

*kahka-kewatik* (raven tree, Cree); *kahka-kiminiatik* (crow berry, Cree)

*mbethi" dzhi* (owl berries, Slave)

*Waldholder* (woods elder, modern German; see also *Sambucus*); *Wacholder* (modern German; *Weckholder* in 1542; probably from *wachen*, guard, be awake, meaning evergreen; the Middle High German *queckholder* comes from *queck*, making alive; *Quêkis* [branches] were used in rituals to beat people and animals to ensure fertility)

***Juniperus sabina*** (Latin *sabina*, juniper; Old World only)

*'ar'ar* (Arabic)

*chedraia* (Greek)

*ciye* (Coptic)

savin [saffern, saffron] (came into English about A.D. 1000 from Old French *savine*, from Latin *sabina*, juniper); *sabina* (Portuguese, Spanish by 1542); *samban* [*samhan*] (Gaelic, the plant is not native to northern Europe, and the Romans surely introduced it and its name; the Gaelic word has other meanings that predated this use); *sauine* (Italian in 1542, now *savina*); *sauinier* (*savine* tree, French in 1542); *savelboom* (savin tree, Dutch in 1542); *Sevenbaum* (savin tree, German in 1542)

***Junipems virginiana*** (from Virginia) (= *J. salicicola* fide Wunderlin 1998; *J. virginiana* var. *salicicola* fide Adams 1993)

*acini* (Mikasuki); *vcénv* [*acinâ*, *achena*, *auchenau*, *auche-nau*] (Creek, Muskogee; in Levy County, Florida, there is an Atsena Otie Key, from *vcénv*, cedar, *ote*, island); *a'tsina* [*a'-tsi-na*', *a-tsi:-n*', *ajina*] (loan-word from Creek, Cherokee)

*atcuwe* <sup>se'</sup><sub>se</sub> *wyhukse*'; *aswetci*'here (Catawba; cognate or loan related to Creek?)

[Carolina, coastal red, southern red (the Florida form)] cedar ("cedar" came from Middle English and Old French *cedre*, taken from Latin *cedros* and Greek *kedros*, used in English by about A.D. 1000; the modifier "red" was applied to distinguish the American from the Old World species); *cèdre rouge* (red cedar, Quebec)

*chowwaala* [*chowaala*, *chowahla*] (Alabama); *chuala* [*chuatla*] (Choctaw); *chowaala*' [*chowa hla*', *chohwala*', *chomahala*', *chawala*] (Chickasaw)

*ekawai:pv* (Comanche)

*genévrier* (Quebec); juniper-bush; red juniper

*hante* [*hante sha*] (*hante*, eggs, *sha*, red, Dakota)

*icuwése* (Catawba)

*khicuc* [*khishoush*] (Atakapa)

*'ko-kee-dd-la* [*a-heeñ*] (conspicuous, Kiowa)

*maazi* (Omaha-Ponca)

*mehokhócus* (Delaware); *miskawa'wak* (red wood, Ojibwa)

*moroke* (Strachey identified this word as the "cedar" in [1612] 1953; it is not mentioned by Siebert 1975; cognate with Delaware and Ojibwa?)

*noehntotakri* (*ojenta*, wood, Onondaga)

pencil-wood (formerly popular for making lead pencils)

*sabina* [*Colorado*] ([red] cedar, New Mexico); savin [red savin, *savine*]

*sequaw* (probably meaning red, Shawnee, fide Edgar 1891)

*tar* (Yuchi)

*tawatsaako* (Pawnee)

*xon-dse hi* (*zhu-dse*, red, *hi*, tree, Osage)

*ya-'ton-ba* (wood for love flute, Kiowa)

Since the time of the classical Greeks and Romans, two species of *Juniperus* have been recognized in Europe, the juniper and the savin. Greek author Dioscorides (fl. A.D. 40–

80) and Roman herbalists Galen (A.D. 129–?200) and Pliny (A.D. 23–79) discussed both species (Meyer et al. 1999). Because these two Old World species contributed heavily to the names used for American plants, they are listed above with scientific and common names.

During the Middle Ages, Europeans thought that juniper smoke gave protection against contagious diseases, particularly the plague and leprosy (Dobelis 1986). This belief prevailed even in the times of Rembert Dodoens, who wrote in 1616, “Juniper or the berries thereof burned driueth away...all infection and corruption of the ayre.” Northern Europeans burned juniper during childbirth to prevent the *aillse* (fairies, Gaelic) from substituting a changeling for a newborn. Up until the early 1900s, many people in the British Isles believed “that he who cut down a juniper would die within a year” (Vickery 1995).

Those practices were likely holdovers from earlier times, probably going back to Gaelic and classical Greek and Roman cultures. Junipers have been considered wondrous by every culture living where the plants grow. Indigenous Americans consider them sacred.

*Juniperus communis* has given us two other familiar words. “Geneva” is an Anglicized version of the French *genève*, juniper, used for the city in Switzerland. The other word names a product that is said to have originated in Holland, where its Dutch name has been *genever*, juniper, since at least the 1500s. However, the product now is known as “gin,” a highly contracted version of “Holland’s geneva.” This is an alcoholic drink made from grain and flavored with the crushed “berries” of *J. communis*. In addition, the fruits are used to flavor game, stuffings, marinades, and stews (Bremness 1994).

Harriot ([1590] 1972) may have been the first to record red cedar in the New World although he did not know the Algonquian name for it in North Carolina. He wrote, “Cedar, a very sweet wood & fine timber; whereof if nests of chests be there made, or timber thereof fitted for sweet & fine bedsteads, tables, desks, lutes, virginales & many things else.” Later he noted that others had reported white cedar (see *Chamaecyparis*) but he had not seen it.

Red cedar is prominent in the Cherokee story of “How the World Was Made.” Their story relates that when the first plants and animals were made, they were told to stay awake for seven nights (seven, a holy number). One after the other, the animals fell asleep until finally only the owl and panther were awake. These two were given the power to see in the dark and prey on the others. Of the trees, only the cedar (*Juniperus*) pine (*Pinus*) spruce (*Picea*), holly (*Ilex*), and laurel (*Persea*) were awake on the seventh day. Therefore, “to them it was given to be always green and to be greatest in medicine” (Mooney 1885–1886).

A Yuchi story explained how the cedar got its red wood. A wizard was interfering with the movement of the sun across the sky. Two warriors were selected to dispatch the wizard, and when he appeared, they swung their clubs and knocked off his head. They returned to their people with the head, but it refused to die. The warriors were advised to tie the severed head to the tip of the cedar tree and only there did it die. Before dying the wizard’s head bled through the cedar, staining its wood red. Ever since, cedar wood has been red and the tree a powerful medicine (Lankford 1987).

Cedar wood has long been one of the most prized in the Americas. The Cherokee carved the wood, made fence posts and furniture with it, and used it for mothproofing

(Hamel and Chiltoskey 1975). The Kiowa used the red, aromatic heartwood to make "love flutes" (Vestal and Schultes 1939). The Ojibwa put split strips as fences and thatch on graves, made them into mats, and made cradle boards with the wood (Moerman 1998). The Potawatomi wove mats and bags from the bark (Smith 1933, King 1984). The Thompson people made a fuel of the wood for smoking skins to color them dark (Moerman 1998).

Wood has been used for novelties, posts, woodenware, millwork, paneling, closets, chests, and pencils (Vines 1977). The aromatic wood still is prized for chests because people think it repels insects. Porcher (1863) wrote: "The wood of this tree is well known. It is sometimes dug up in the mud of our swamps in a perfect state of preservation. It is aromatic, light, soft, bearing exposure to water and weather, and suitable for all kinds of cabinet work, in the construction of posts, staves, the inner work of houses, and particularly in the building of boats. Cedar boxes are not infested by insects, moths, etc., and are used for storing away woollens. The leaves also prevent the attacks of insects when spread over cloth."

Bark was used to build houses, wigwams, wickiups, and mats by the Ojibwa (Moerman 1998). They also used shredded bark as padding on cradle boards. The Potawatomi made bags from the fibers (Whitford 1941).

To the people in the Missouri River region, the tree was sacred to their legendary thunderbird. Therefore, the Lakota, Omaha, Pawnee, and Ponca put boughs on tipi poles to avert lightning (Gilmore 1919). Various versions of the "thunderbird" story existed throughout southeastern tribes, and perhaps they had a similar use of red cedar (Lankford 1987). Indeed, people as distinct as the Ojibwa and Navajo considered the trees capable of averting evil and burned branches as incense or carried wands in ceremonial dances (Moerman 1998).

Although Moerman (1998) listed all but three of the 13 species known in North America (Adams 1993), and three entries under *J. virginiana*, he does not include all the Muskogean who used these plants.

The Chickasaws warmed the ends of cedar limbs in water with elder (*Sambucus*) and placed them on the head to alleviate severe headache (Swanton 1928b). The Creeks used cedar fumes to relieve cramps in neck muscles (Swanton 1928a). The Alabamas boiled sprigs for warm applications to rheumatic pains (Swanton 1928a). The Chickasaw's neighbors, the Choctaws and Natchez, used cedar for muscular pains, swollen legs, and mumps (Swanton 1928a).

More details are recorded among the Seminoles than any other southeastern group. They use the southern red cedar (*J. virginiana* var. *salicicola*) to treat cold symptoms (including cough, runny nose, stuffy head, and sore throat) and swollen joints (decoction as body rub and steam bath). Additionally, red cedar was used to treat "Eagle Sickness" (stiff neck and back), "Fawn Sickness" (swollen legs and face), "Ghost Sickness" (dizziness, staggering), "Hog Sickness" (unconsciousness), "Mist Sickness" (eye disease, fever, chills), "Opossum Sickness" and "Raccoon Sickness" (children dreaming about these animals), "Rainbow Sickness" (fever, stiff neck, backache), "Scalping Sickness" (fever, headache, backache), and "Thunder Sickness" (fever, dizziness, headache, diarrhea). A decoction was used as an emetic during religious ceremonies and to make a witchcraft medicine. Branches were kept with eagle tail feathers to prevent the powerful plumes from causing sickness (Sturtevant 1955).

The Ojibwa and Meskwaki also used cedar for headache and to season other medicines (Vogel 1970). Fruits to the Dakota were *hante itika* (cedar eggs), and they were boiled with leaves for a decoction used to treat coughs (Gilmore 1919). Smoke from burning twigs was inhaled to cure colds. Juniper was also used by the Omaha in ceremonial cleansing. Red cedar was used as medicine and incense by at least the Alabama, Cherokee, Chickasaw, Comanche, Cree, Creek, Dakota, Delaware, Iroquois, Kiowa, Lakota, Meskwaki, Natchez, Ojibwa, Omaha, Pawnee, Ponca, Rappahannock, Seminoles, and Salish (Moerman 1998).

The chemistry of *Juniperus* has been comparatively well studied. To everyone's surprise, the genus contains the antibiotic podophyllotoxin, originally known from *Podophyllum* (which see) in the Berberidaceae (Lewis and Elvin-Lewis 1977). Otherwise, there is considerable variation in the other compounds present in different species.

The Old World *J. sabina* contains sabinol, sabinyl acetate, perpinene, pinene, sabinene, decyl aldehyde citronellol, geraniol, cadinene, and dihydrocuminyl alcohol. However, *J. virginiana* is so similar that it is sometimes substituted commercially for *J. sabina* (Lawless 1995). These compounds are considered powerfully anthelmintic, diuretic, emmenagogue, rubefacient, stimulant, and a vermifuge, but they are so potent that they "should not be used in therapy, whether internally or externally" (Lawless 1995). Duke et al. (2002) admonish that extracts from *J. virginiana* may be fatal.

### *Justicia*

(Named for the Scottish horticulturist James Justice, 1698–1763, who was elected a fellow of the Royal Society in 1730)

***Justicia angusta*** (narrow, the leaves) (reported as *J. crassifolia*)  
*akciswantá:ci:kí* (penis hardener, Mikasuki); *haswâ: isfâ: pi:ckâ* (*hvsww*,  
 penis, *enfapetv*, erection, Creek)  
 loose-flower water-willow [looseflower waterwillow]

Wunderlin (1998) lists seven species of *Justicia* in Florida, with three of these having been introduced from elsewhere. *Justicia angusta*, *J. cooleyi*, and *J. crassifolia* are endemic.

Micosukee Josie Billie told Sturtevant (1955) about this plant that would "restore the virility to a man sixty to a hundred years old." A dried piece of the plant was kept by a man who knew the song that enabled the treatment. The song was considered "dangerous" and valuable. Billie said he would not refuse to treat any man who asked for the cure.

Sturtevant (1955) wrote of the plant, "probably *Justicia crassifolia*." That determination seems unlikely. *Justicia crassifolia* is endemic to a small region in Hernando, Sumter, and Lake Counties. Therefore it seems unlikely that these would have been the plants used by the Seminoles. Much more likely is *J. angusta*, a plant widespread through the southern end of the peninsula. Doubt prevails because this is not one of the plants identified by Roy Woodbury for Sturtevant (1955).

*Justicia pectoralis* was introduced by the Cubans (and probably by other Latin Americans) as a medicinal plant from their homeland that they call *tilo*. That is the same word used in Spanish to designate *Tilia*, and there are similarities in the way these unrelated plants are used (see *Tilia*). This *Justicia* is famous for use throughout the Americas as a calming tea, among other uses (e.g., Schultes and Hofmann 1979).

# K

## *Kallstroemia*

(In honor of A.Kallstroem, an obscure contemporary of Johann Anton [Giovanni Antonio] Scopoli, 1723–1788, Austrian physician and professor of natural history at Pavia, who named the genus)

***Kallstroemia maxima*** (largest)

*abrojillo* (little bur); *arbojo* [*terrestre*] ([land] bur, Cuba, Dominican Republic, Puerto Rico, Nicaragua, Colombia)

*atarraya* (something that detains or catches, Puerto Rico)

*batatilla* (little potato, Dominican Republic)

*caldero* (little cauldron, Puerto Rico)

*caltrop* [big, greater] (“caltrop” probably came from Latin *calcum*, heel, and *troppa*, trap or snare, and has been applied to a number of thorny or spiny plants. First applied to plants ca. A.D. 1000, and to *Tribulus* by 1511. Later applied to *Kallstroemia* and to an instrument of war ca. 1300. By the early 1500s, this trap was a ball with four sharp prongs or spikes so that one always stands upright regardless of how it falls on the ground; USA, Bahamas, Puerto Rico.)

*câpre marron* (wild caper, Haiti)

centipede root (Virgin Islands)

*chax-chauxnuc* (a name usually applied to *Tribulus cistoides*, but occasionally to *Kallstroemia* by confusion; *chak*, red, *xnuuc*, old; the name “*xnuuc*” or “*viejo*” is given to the ferruginous pygmy-owl, *Glaucidium brasilianum ridgwayi*, and the spines on the fruits remind people of its feathered “ear” tufts, Maya, Quintana Roo)

*cresson courant* (twining [literally, running] cress, Guadeloupe, Martinique)

*golondrina* (dove, El Salvador)

*guía* [*hierba*] *de parra* (grape vine, El Salvador)

*hierba* [*yerbax*] *de pasmo* (herb for *pasmo*, a disease with fever and aching bones, from Latin *spasmus*, Venezuela)

*hierba de polio* (chicken herb, El Salvador, Panama, Colombia)

*jepo*

longlo (maybe from “long” and “low,” describing the growth habit, Virgin Islands)

*maconcherie* (probably a mistake for *macoucheri*, as in the Macoucheri Estate, Dominica)

*mata* (wild plant or thicket, Costa Rica)

*ni* (Huastec, San Luis Potosí)

pale-flowered turkey blossom (Jamaica)

parsley (Cayman Islands)

*patagon* (big foot, Martinique)

*perrito* (little dog, Colombia)

police *macca* (*macca* means a thorn; so the name means that the thorns prevent a person from going to a particular place, in the same way the police would deter them, Jamaica)

*pourpier bâtard* (false purslane; *pourpier* is from Vulgate Latin *polpie*, in turn from *pulli pedem*, chicken foot, Guadeloupe, Martinique); *pourpier courant* [*rampant*] (twining [creeping] purslane, Martinique)

*shanapmucui* (Belize)

*talcacao* (maybe comparing these to the plant that Hernández called *tlalcacauatl*, the peanut, *Arachis hypogaea*, Náhuatl, Costa Rica)

*taraya* (this looks like an orthographic version of *tlalca* or *tlalza*, El Salvador)

*tlalcacauatl* [*tlalca-cauatl*] (probably from *tlalzahuatl*, where *zahuatl* is mange, because of the chiggers, *Eutrombicula*, that they harbor; in Sonora, the Mayo call *Kallstroemia* the *jimiri*, chiggers, because of that problem)

*verdolaga* (purslane or *Portulaca*, Yucatán, El Salvador, Costa Rica, Venezuela); *verdolaga blanca* [*de caballo*, *de monte*] (white [horse, wild] purslane, El Salvador); *verdolaga de abrojo* (bur purslane, Puerto Rico); *verdolagueta* (little purslane, El Salvador)

*xichilak* [*xichiak*] (*xich'il*, something that is hard or flexible and not easily broken, *ak*, vine, Maya, Yucatan, Quintana Roo)

*yerba de gallina* (chicken herb, Guerrero)

Two genera that have always given me trouble are *Kallstroemia* and *Tribulus*. When in fruit they are not that difficult to recognize. Fruits are prickly in *Tribulus* and tuberculate in *Kallstroemia*. Otherwise, one has to count the carpels—4 to 5 in *Tribulus*; 8 to 12 in *Kallstroemia*. Both genera have tropical affinities, and grow mostly in Florida's peninsula.

It turns out that Linnaeus ([1753] 1957) did not distinguish these two genera either. He called this species *Tribulus maximus* after studying plants cultivated at the *Hortus Cliffortianus*. Linnaeus had also studied the illustrations in Hans Sloane's book, *Catalogus plantarum que in insula Jamaica sponte proveniunt* (Catalog of Plants Growing Wild on the Island of Jamaica). Except for the cultivated plants, he knew the species only from Jamaica.

We now know that *Kallstroemia* is a genus of 17 species, mostly in the American tropics (Porter 1969). Florida has the single species scattered around the state that locally appears and disappears. Deeper in the tropics, the plants are more abundant and frequent.

People in El Salvador and Colombia sometimes cook young plants of *K. maxima* and eat them (Standley 1928, Pérez-Arbelaes 1978). Using them as food, however, is not a common practice. Moreover, it is typically done when nothing else is available.

A more common application is in medicines. Pittier (1957) wrote that Costa Ricans crush leaves and apply them to boils and other sores to bring them to a head. In Cuba, decoctions of the plant are applied to various skin problems, and either a decoction or an infusion is used to combat urticaria (Roig 1945, Leon and Alain 1946–1953, Liogier 1978). In Colombia, the herb is considered a diuretic and laxative (PérezArbelaez 1978, Morton 1981). Costa Ricans and Venezuelans make a poultice to treat abscesses and tumors (Pittier 1957, Morton 1981).

Bremness (1994), Bown (1995), and Duke et al. (2002) do not mention these largely tropical plants. Hocking (1997), on the other hand, notes that decoctions of the plants have been used to treat skin diseases and that the leaves are mildly purgative.

It has been known for a long time that domestic animals are sometimes poisoned by *Kallstroemia* (Dollahite 1975, Wilson et al. 1982). Among the potent chemicals in the genus are saponins (Dominguez et al. 1985, Filho et al. 1989). In addition, the plant contains diosgenin and has been suggested as a commercial source of that compound (Khanna et al. 1981, Datta et al. 1983). That chemical is now commercially taken from *Dioscorea* and is a major element in building hormones (Lewis and Elvin-Lewis 1977).

### *Kalmia*

(Named by Linnaeus for his student Pehr or Peter Kalm, 1716–1779, who explored northeastern North America; subsequently, Kalm was professor of economy and natural history at Åbo, modern Turku, Finland)

***Kalmia latiflora*.** From Sargent 1905.

***Kalmia latiflora*** (broad-leaved)

*Berglorbeer* (mountain laurel berry, German)

big-leaf ivy [big-ivy]; ivy[-bush] (“ivy” came from Old English *ifig*, and dates to about A.D. 800, originally applied to *Hedera helix*, and later to other evergreens); poison ivy (in use in the South during the Civil War by local farmers, fide Porcher 1863)

calico-bush (“calico” came into English about 1505, as a variant of the Indian city Calicut on the Malabar coast; it was applied to a cotton cloth ca. 1589; these plants had this name by 1847)

*grand [gross] Kalmie* (big kalmia, German)

lamb-kill (a note on its toxicity when browsed by domestic animals)

[American, mountain, rose-, round-leaved, sheep-] laurel (“laurel” derived from Latin *laurus*, originally applied to *Laurus nobilis*, and later to a number of similar plants; the modifiers distinguish this from the Old World species)

*Lorberrose* (rose laurel, German)

spoon-wood [spoonwood, spoon tree] (“spoon tree” dates from Kalm’s book of 1753; by 1847 it became “spoon-wood” and was equated with “calico-bush” and “mountain laurel”)

*wicke* (probably from an Algonquian word, Quebec)

According to Lewis and Elvin-Lewis (1977) and Foster and Duke (1990), the resins in *Kalmia* are among the most poisonous known. All plant parts contain andromedotoxin, a toxic diterpene causing slow pulse, lowering of blood pressure, lack of coordination, convulsions, progressive paralysis, and death. Arbutin, a glycoside of hydroquinone, is also present and poisonous (Lewis and Elvin-Lewis 1977). Surely Linnaeus was focusing on the beauty of the flowers when he named the genus after his student. We have every reason to believe that he considered the patronym a compliment (Reveal 1992a). Indeed, Kalm ([1753–1761] 1972) wrote, “Dr. *Linnaeus*, conformable to the peculiar friendship and goodness which he has always honoured me with, has been pleased to call this tree *Kalmia latifolia*.”

Linnaeus had not seen living plants of *Kalmia* as he had so many of those in *Species Plantarum*, which appeared the same year as the first part of Peter Kalm’s *En resa til Norra America* (Travels into North America). In Kalm’s book he used the binomial given by his mentor and called the plants both “American dwarf laurel” and “spoon tree.” Kalm noted that the Swedes of New Jersey called them spoon-tree because the indigenous people who formerly lived there “used to make their spoons and trowels of the wood of this tree.” He brought a spoon back to Sweden with him. He gives no detail beyond “made by an *Indian*,” but it was made on the site of Philadelphia, so the maker was probably Delaware.

Catesby (1734–1747) noted that deer fed on the leaves with impunity, while cattle and sheep died. Kalm himself wrote, “Their leaves are poisonous to some animals, and food for others.” He added that deer ate the plants and the dogs became poisoned after eating the offal from butchered animals. People who ate the stag meat, however, had no problems.

Indigenous Americans knew of the poisonous nature of *Kalmia*, even though Europeans like Mark Catesby focused on the beauty of the flowers. The Cree, Delaware, and Mahuna considered the plants poisonous (Lewis and Elvin-Lewis 1977, Moerman 1998). However, the Cree still used the leaves as medicine (Moerman 1998). The Cherokee also used *Kalmia* as medicine (Hamel and Chiltoskey 1975). Leaves or an infusion of leaves were used to treat pain from rheumatism and brier scratches and cramps in ballplayers. They also made a salve from leaves, which was used “for healing.” An infusion was assured to rid a person of vermin.

Porcher (1863) wrote: “A writer under the signature of ‘Cunio’ communicates the following to the Atlanta Commonwealth,’ 1861...Mr. Charles Foster, long known as a wood engraver at Nashville, Tennessee, many years since, I can state that the wood of the maximum or mountain laurel, as well as its confrere, *Kalmia latifolia*, known by every

farmer as poison ivy, are equalled only by the best boxwood.” Farther on, Porcher recorded that physician Dr. Shoemaker “reports cases of obstinate diarrhoea cured by a decoction, thirty drops being taken four times a day. The leaves have been advantageously used in syphilis, and extensively applied in tinea, psora, and cutaneous affections. Dr. Barton states that nervous symptoms have resulted from the external use of the strong decoction, thirty drops taken internally six times a day producing vertigo.... Dr. Shoemaker supposes it suitable to cases of hypertrophy of heart, and other diseases, when it is necessary to decrease the action of that organ; and from the tannin present that it is peculiarly fitted for cases of hemorrhage, dysentery, etc. He proposes that two ounces of the leaves be macerated in a pint of alcohol for a week, and then strained, the dose of which for an adult is thirty drops every two or three hours. If these observations are confirmed it will give the plant a high reputation as a sedative, and attention is invited to it.” These applications in minute doses were often effective, but always dangerous (Foster and Duke 1990).

### *Koanophyllon*

(Perhaps from Greek *choane*, funnel, and *phyllon*, leaf)

***Koanophyllon villosum*** (shaggy pubescent or hairy) (= *Eupatorium villosum*)

*albahaca de sabana* (savanna basil, Cuba); *albahaquilla* (little basil, Cuba)

bitter bush [brush] (Jamaica); bitter sage (Bahamas)

*filigrana* (literally filigree, but also used as a common name for aromatic *Callicarpa* and *Lantana*, Cuba)

Florida Keys [velvety] thoroughwort (Florida) jackmada (Bahamas)

*rompezaragey de sabana* (savanna shoe breaker, Cuba); *rompezaragüey* (shoe breaker; a name also used for *Conoclinium* and *Vernonia*, Cuba)

*travesera* (misbehaving one, Cuba)

*trebolillo* [*tribulillo*] (little clover, *trebolo* from Latin *trifolium*, Oriente, Cuba)

*yerba amarga* (bitter herb, Cuba)

*zanca de grullo* (crane's stilts, also used for *Chromolaena odorata*, cf. bitter bush, Cuba)

One of Linnaeus's students, Olaf Peter Swartz, found these plants in Jamaica and named them *Eupatorium villosum* in 1788. Later, this genus was named by Manoel Arruda de Camara (1752–1810) in his *Travels in Brazil* published in 1816. The segregate genus was subsequently ignored by virtually all who studied the plants, and instead included as a synonym under *Eupatorium* (e.g., Chapman 1897, Small 1933, Alain and Leon 1946–1953). Robert M. King and Harold Robinson resurrected the genus in 1975. *Koanophyllon* now comprises about 120 species endemic to the American tropics (Mabberley 1997).

This is a shrub that grows in the Bahama Islands, Florida, Jamaica, and the Cayman Islands. It is particularly prone to growing in calcareous substrates, which perhaps explains why it is confined to the Florida Keys and Everglades Keys.

In Cuba, the entire plant is used in decoctions against diarrhea and other intestinal problems (Roig 1945). Other Cubans use it in baths to relieve the pain of rheumatism and as an astringent. In Jamaica it is a remedy for treating cholera and diarrhea; it serves as a diuretic, and the leaves or twigs are employed to reduce fever. Leaves are chewed to relieve flatulence in the Bahamas (Hocking 1997).

Chemical studies indicate that *K. villosum* has diterpenoid lactones (Manchand et al. 1979). Other species in the genus also have diterpenoid lactones and sesquiterpene lactones (Bohlmann et al. 1981, 1984, Jakupovic et al. 1987, Schuster et al. 1992).

### ***Kosteletzkya***

(Commemorates the Czech botanist Vincenz Franz Kosteletzky, 1801–1887, physician and professor of botany in Prague)

***Kosteletzkya virginica*.** From Britton and Brown 1897.

#### ***Kosteletzkya virginica*** (from Virginia)

fen rose

marsh-mallow (originally *Althaea*, later extended to *Hibiscus*, which see, and *Kosteletzkya*)

*oopaake embakshe* (*oopaake*, owl, *em*, its, *bakshe*, threads, Mikasuki);  
*opv 'mvhoswv* (*opv*, owl, *em*, its, *vfuswv*, threads, Creek)

*oopaake oshtaape shapokey* (owl boots, Mikasuki); *opv enhvyftehkv*  
(*opv*, owl, *em*, its, *sohtehkv*, boots, Creek)

Snow and Stans (2001) record that the Seminoles use *Kosteletzkya virginica* for cramps, heat, and to induce labor. The related species *K. pentasperma* is used in Jamaica and Nicaragua (Morton 1981, Coe and Anderson 1996).

***Krameria***

(Apparently named for the Austrian army physician,  
Johann Georg H.Kramer, d. 1742)

*cadia de perro* (dog bur, Curasao)

*cósahui* (Yaqui)

*crameria* [*clameria*, *grameria*] (Mexico); *krameria* (introduced into  
England in 1806, presumably with the common name; soon afterward,  
bloodred extracts were used to adulterate port wine)

*mesquitillo* (little mesquite, Spanish)

*raíz de culantrillo* (parsley root, Mexico)

***Krameria lanceolata*.** a. Habit, b. Flowering branch, c. Three views of the flower, d. Elaiophore. e. Fruit, f. Fruit spine. *Drawn by M.C.Ogorzaly.*  
From Simpson 1989.

*ratany* [rattany] (in English by 1808, from *ratdnia* [or *ractania*,  
*ratafia*], maybe from Quechua, meaning “ground-creeping” fide Simpson  
1991)

*wetahupatci* (Tarahumara)

***Krameria lanceolata*** (with leaves shaped like lancepoints)

*clameria* [*crameria*] (Mexico)

*mezquitillo* (little mesquite, Mexico)

mountain burr

prairie bur

*raíz de cucillo* (little cuckoo root, Mexico)

*ratanhia du Texas* (Texas rhatany, Paris)  
 sandspur (a name better known for *Cenchrus*, but both have spiny  
 fruits, Florida)  
 Texas [trailing] ratany [root]  
*ticara* (Chile)

*Krameria* is a small genus, with 18 species found from the southern United States to northern Argentina and Chile (Simpson and Salywon 1999, Simpson et al. 2004). There are two unusual traits about the family, in addition to their zygomorphic flowers and spiny fruits. Members of the genus are hemiparasitic, forming haustoria on the roots of a broad range of host plants (Musselman 1975, 1977). Flowers of *Krameria* are nectarless, and the rewards for visitors are fatty oils produced by modified external surfaces of the lower two petals (elaiophores). *Krameria* actually depends on oil-collecting bees and only *Centris* (Anthophoridae) has been reported visiting their flowers. A given *Centris* species or even individual, on the other hand, will visit other oil-producing plants, using the oils from the flowers for their larval food (Simpson and Salywon 1999).

The genus was named by Pehr Löfving (1729–1756), a Swedish student of Linnaeus. During his travels as one of Linnaeus's "Disciples," Lofling went to Venezuela, where he died. After his death, his book *Iter Hispanicum* was published in 1758, and in it he created the genus and described *K. ixine*. The genus is the only one in its family and has formerly been allied with the Fabaceae or the Polygalaceae. Recent molecular work (Chase et al. 1993, Gadek et al. 1996, Sheahan and Chase 1996, Savolainen et al. 2000, Soltis et al. 2000, Simpson et al. 2004) has shown that *Krameria* is most closely related to the Zygophyllaceae.

Linnaeus accepted Lofling's genus and species and changed the *ixine* to *ixina*, but *ixine* is the correct spelling (Simpson 1991). Now it is known that *K. ixine* grows in Puerto Rico, Hispaniola, the Lesser Antilles, Guatemala, Nicaragua, Honduras, Costa Rica, Colombia, Venezuela, and eastern Guyana. In Puerto Rico, it is known as *abrojo Colorado* (red bur) and *ratania falsa* (false ratany). Elsewhere it is known as *cadia del per ro* [*cadilla del perTO*] (dog bur, Venezuela), *carreton* (roadside thing, Colombia), *estancadera* (resembles hips, Colombia), *pegasaja shimaron* (wild sticker, Curasao), *ratanhia das Antilhas* (Antillean ratany, Brazil), *ratanhia de nova grande* (new big ratany, Brazil), and *ratanhia de sabanilla* (little savanna ratany, Brazil).

Hipólito Ruiz first found the South American plants being chewed by a Peruvian woman. She told him that they were useful to whiten and strengthen the teeth (Simpson 1991). At that time, no other uses by indigenous people were known, but Ruiz began experimenting with the plants. Later, he extolled *ratánia*'s virtues and a variety of internal astringent uses were instigated in Peru and Spain. The medicine was introduced into England in 1806 and into Germany in 1818.

People in Curaçao use *Krameria* to ease intestinal irritations, as an emmenagogue, to promote easier childbirth, or even as an abortifacient (Morton 1981). In Venezuela, the decoction is used for liver and kidney problems. Brazilians use it to treat dysentery (Mors et al. 2000).

Four species of *Krameria* in addition to *K. lanceolata* grow in the southern United States (Correll and Johnston 1970, Simpson and Salywon 1999). *Krameria erecta* is known from California, Nevada, Utah, Arizona, Baja California (Norte and Sur),

Chihuahua, Coahuila, Durango, San Luis Potosi, Sinaloa, Sonora, and Zacatecas. Rea (1997) has records of *K. erecta* being made into astringent medicines and dyes by the O'odham (Pima, Papago). The Mayo of Sonora know this species as *tajimsi* (sun beard), and others in the area say *tajuí* (Spanish) and range ratany. The Mayo also use the roots in astringent medicines and in dyeing (Yetman and Van Devender 2002). The Guarijio call it *tahué* [*tajué*] and use it for healing sores, much as do their neighbors the Mayo (Yetman 2002). The Seri call *K. erecta* the *haxz iztim* (dog's hipbone), but Felger and Moser (1985) record no use of this species. *Krameria erecta* is uncommon while *K. grayi* is common in the Seri region, and they do use it.

The similar *K. grayi* grows in much the same area as *K. erecta*. Both extend into Texas, with *K. erecta* occurring commonly in west Texas. *Krameria grayi* was used similarly among the Paiute (Great Basin) and Shoshoni (Nevada, Montana). The Pima also made a brown dye from it for baskets (Curtin 1949). Rea (1997) found the Pima calling the plants *eedho* [*oeto*], and many remembered its use as a red dye, but that practice has recently fallen into disuse. Some of the older people still remembered it being used for internal problems, particularly rheumatism. The Tohono O'odham (Papago) distinguish between *eedho* (*K. grayi*) and *ge'eged eedho* (large krameria, or *K. erecta*), and one of Rea's informants said the two were used interchangeably as medicines. Kay (1996) found *K. grayi* called *temitzo* (Ópata), *chacate* (Maricopa), *heepol* (Seri), *cosahui* [*cosagui*] (Yaqui, maybe a loanword from Nahuatl, where it means "yellow"), and white ratany. The Maricopa chew the roots for sore throat, take a tea of it for fever and coughs, and put it on the umbilical stump to prevent infection (Kay 1996). The Yaqui consider the plants good for the blood; The Tarahumara make a medicine for aching teeth (Kay 1996). The Seri historically used the roots of these plants to make a reddish brown dye for baskets (Felger and Moser 1985). The Seri also made a tea for upset stomach and diarrhea, and sprinkled powdered stems on skin sores that were slow to heal.

*Krameria ramosissima* is even more similar to *K. erecta*. Oddly enough, it is not the sister species of *K. erecta*, but basal to a clade containing *K. erecta* (Simpson et al. 2004). *Krameria grayi* is in a totally different clade; it is restricted to Texas (Brewster and Val Verde to Hidalgo Counties), and then south only into Coahuila, Nuevo Leon, and Tamaulipas. No uses were found for *K. ramosissima* (Simpson 1991).

*Krameria lanceolata* differs from the other U.S. species in that it is herbaceous and its branches sprawl on the ground. This is the most widespread species in the United States, known from Colorado and Kansas south to Arizona, New Mexico, and Texas, and east to Georgia and Florida. It also grows in Chihuahua and Coahuila in Mexico. Martinez (1969) said that *K. lanceolata* grows as far south as the Valley of Mexico, but that seems to be confusion with *K. secundiflora*.

Although *K. lanceolata* has the widest range in the United States, it is not recorded as used among indigenous people there. However, other cultures record the roots as an astringent medicine (Hocking 1997). According to Simpson (1989), Burlage's 1968 *Index of Poisonous Plants of Texas* reported that the species was used to make a medicinal tea to combat diarrhea, hair and teeth loss, and cancer of the tongue.

Martinez (1969) said no distinction is made among the Mexican species; all are used as an astringent. They are employed to treat diarrhea and for skin and gum sores.

Martinez (1969) noted that a Dr. L. Hernández Chávez had used them with some success in treating cancer of the tongue, stomach, and intestines.

Simpson (1991) provided convincing evidence that *Krameria* was not typically used as an internal medicine before 1843. She argues that the indigenous use of various species “followed the recognition of their being related to ‘true’ ratany and subsequent substitution for that species.” Also because reports from South America postdate 1800, she was convinced that “modern” indigenous uses as a medicine were derived from contact with Old World people. Her argument is not as convincing regarding use for the teeth and sores.

Roots of *Krameria* contain sugars and TV-methyl tyrosine (Simpson 1991). *Krameria* is also rich in catechin tannin (Nierenstein 1931, Morton 1981, Mors et al. 2000). More recent study has revealed procyanidin and complex polyphenols, which are formed from catechin and epicatechin (Scholz and Rimpler 1989). There are also neolignans and norneolignans in some species, including *K. lanceolata* (Achenbach et al. 1989).

Some of the species have been reported as being antiviral and inhibitory to *Bacillus cereus*, *B. subtilis*, *Escherichia coli*, and *Staphylococcus aureus*; others are hypotensive (Kay 1996). Duke et al. (2002) recommend *K. lappacea* as antihemorrhagic, antiinflammatory, antiseptic, astringent, expectorant, fungicidal, and vulnerary, and most sources agree that many species are as effective. *Krameria* is used today in food additives and specialty toothpaste (Simpson 1991).

### *Krigia*

(Named in 1791 for German physician David Krig or Krieg, 1670–1710, who was among the first to gather plants in Maryland; he collected there in 1698)

#### *Krigia virginica* (of Virginia)

dwarf dandelion

Virginia dwarf dandelion [Virginia dwarf dandelion]

*Krigia* is a genus with seven species endemic to North America (Ki-Joong and Turner 1992, Mabberley 1997). The small herbs were collected by John Clayton in the 1730s and sent to Jan Gronovius in the Netherlands. Gronovius called them *Hyoseris*, and Linnaeus ([1753] 1957) dubbed them *H. virginica*. It was not until 1803 when Carl Willdenow revised *Species Plantarum* that the species was placed in *Krigia*.

Clayton was not the only person to find these plants along the eastern coast of North America. Thomas Walter also found and named them in his *Flora Caroliniana* of 1788. They were named again by William P.C. Barton in his *Flora Philadelphia Prodrum* of 1815, and by Thomas Nuttall in the *Genera of North American Plants* of 1818.

Although these small herbs resemble dandelion (*Taraxacum officinale*), they were not mentioned by Fernald et al. (1958) as edible. Still, Hocking (1997) said that they were used for food like dandelion. He added, apparently from personal experience, that they were “much like that plant.”

No other mention has been found of these herbs being used by people in North America until very recently. Some of the species are now considered attractive and are

cultivated (Mabberley 1997). The *Hortus Third* (Hortorum 1976) lists three species in cultivation.

There is indirect evidence that indigenous people may have used these composites. Moerman (1998) found that the Menomini made a hunting lure from *K. biflora*. These people lived in Wisconsin and used the stem to imitate the cry of a fawn in distress. That noise would sometimes attract a doe.

### ***Krugiodendron*: Black Ironwood**

(Dedicated to Carl Wilhelm Leopold Krug, 1833–1898, the German consul in Puerto Rico, businessman, botanist, and patron of the sciences, who studied the West Indian flora; Greek *dendron* makes a name that means “Krug’s tree”)

***Krugiodendron ferreum*. Drawn by  
P.N.Honychurch.**

Not long after moving to Florida, I discovered a wonderful fragment of tropical hardwood forest (hammock) along the coast in Boca Raton. Eventually, the parcel was purchased along with the beachfront and made into two preserves—the Patch Reef Park and Gumbo Limbo Nature Center. Within the hammock forest, I found trees lying on their sides and others with their tops broken out but still living. These trees were damaged by the hurricanes that hit the site in the mid-1940s (1946, 1947), yet they still dominated the forest. One tree that had not fared so well was a large black ironwood (Florida, Jamaica, Puerto Rico). On the ground beside the tree was the heart of a large trunk that had been snapped by one of the tropical storms. That heartwood was so hard that it remained essentially unchanged during the 31 years that I showed it to classes going through the site. Due to the kindness of my last undergraduate class and the nature center, that 50-odd-year-old branch now hangs outside my office where I watch it turning in the wind each day.

Black ironwood or ironwood (Puerto Rico) was named *Krugiodendron ferreum* by German botanist Ignatz Urban, Assistant Director of the Botanical Garden and Museum at Berlin-Dahlem. The species is *ferreum* (like iron), and the branch outside my office has lasted longer than iron would have in the salt spray of southern Florida's tropical climate.

The name "ironwood" has been used for trees with hard wood by people throughout the world. There are many unrelated species with wood so hard people think it is as "hard as iron." The first usage in English of the term was in 1657, almost without doubt in reference to *K. ferreum*. The publication stated, "Ironwood is called so, for the extreme hardness;... 'Tis much used for Coggs to the Rollers." Among other species that have been called ironwood are *Bumelia lycoides* (North America, Sapotaceae), *Carpinus caroliniana* (North America, Betulaceae), *Copaifera mopane* (Africa, Fabaceae), *Diospyros virginiana* (North America, Ebenaceae), *Erythroxylum aureolatum* (Caribbean, Erythroxylaceae), *Fagara lentiscifolia* (Caribbean, Rutaceae), *Hypelate trifoliata* (Florida, Caribbean, Sapindaceae), *Mesua ferrea* (Asia, Clusiaceae), *Metrosideros vera* (Asia, Myrtaceae), *Notelaea ligustrina* (Australia, Oleaceae), *Olea capensis* and *O. undulata* (Africa, Oleaceae), *Ostrya virginica* (North America, Betulaceae), *Reynosia sepentrionalis* (Florida, Caribbean, Rhamnaceae), *Sideroxylon foetidissimum* (Florida, Caribbean, Sapotaceae), *Sloanea jamaicensis* (West Indies, Malvaceae), *Stadmannia sideroxylon* (Asia, Sapindaceae), and *Xylia dolabriformis* (Asia, Fabaceae).

Other people in the range of *K. ferreum* also make comparisons to iron in their common names for it. They call it *acero* (steel, Cuba), *boafierro* [*guafterro*] (good iron, Dominican Republic), *bois de fer* (iron tree, Haiti, Virgin Islands, Guadeloupe), *bois fer* (iron tree, Haiti), ironberry (Dutch Antilles), ironwood (Florida, Puerto Rico, Virgin Islands), *palo de hierro* [*fierro*] (iron tree, Puerto Rico, Dominican Republic), and *guatafer* (*guata*, padding, *fer*, iron, Hispaniola, Virgin Islands).

Sometimes people compare the wood with other things. Along the lines of comparing it to iron are the names axemaster [exmaster] (Belize), *palo de diablo* (Devil's tree, Cuba), and *quiebra-hacha* [*quebracho*] (ax-breaker, Belize, Guatemala, Dominican Republic, Puerto Rico). The Maya too found the hard wood useful, but instead of cursing it, turned it to good use. They call it *chintoc* [*chim-tok*, *chin-tok*] (*chim*, spear, *tok*, hard, Maya, Yucatán). Formerly, the plant was used to make weapons such as bows, arrows, and lances. Now the wood is used to make work tools. Because of the shine the wood takes when polished Cubans call it *carey de costa* (sea [coast] turtle) and *hueso de tortuga* (turtle bone). The wood color has led to the names *bariaco* (resembling the mahogany colored wood of the *baria* tree, *Calophyllum calaba*, Puerto Rico), *ciguamo* [*siguamo*] (laurel, Dominican Republic), *cocuyo* (also a name for a *Sideroxylon*, Cuba), *coronel* (dogwood, Cuba), and ebony [wood] (Virgin Islands).

Even though I knew the green stems would sink in ocean water, I could not understand the name leadwood (Florida) until I sawed a segment of the tree. The odor of the wood as it heated from being sawed was almost identical to that of molten lead. It is not clear why the tree is called *espejuelo* (little mirror, Puerto Rico) unless the wood can be polished to make mirrors. More likely, the wood has been used as frames for mirrors. The leaves are indeed narrow, eliciting the name *hoja ancha* (narrow leaf, Dominican Republic), but no more so than some of the others with which it grows. Why it would be called *mangel*

*cora* (*cora* =?, mangrove, Dutch Antilles) is not clear, as it grows on ground higher than mangroves.

The species grows in southern Florida, the Bahamas, the West Indies south to St. Vincent and Bequia, and in Bonaire and Curaçao, Yucatán to Guatemala, Belize, and Honduras. In those areas, it is consistently associated with other species in the facultatively deciduous tropical forests. Associated species in Florida include gumbo limbo (*Bursera simaruba*), Guiana plum (*Drypetes lateriflora*), poisonwood (*Metopium toxiferum*), and paradise tree (*Simarouba glauca*). Typically, these are all evergreen, but during years with little rainfall, they have the facility to drop their leaves and become deciduous. This type of forest dominates at least coastal sites throughout the range of black ironwood.

*Krugiodendron* is a monotypic genus containing only *K. ferreum*. Although Urban created the genus in 1902, the species had been known since 1793 when it was named as *Rhamnus ferreus* by Martin Vahl in Hans West's study of the plants of St. Croix in the Virgin Islands. Subsequently, other botanists dealing with the plants really did not know what to do with them. When Augustin-Pyramus de Candolle published the family in his *Prodromus Systematis Naturalis Regni Vegetabilis* in 1825, he decided the species belonged to the temperate North American genus *Ceanothus*. Only a year later, Adolphe T. Brogniart put the species in the tropical genus *Scutia*. In 1859, Grisebach called the trees *Condalia ferrea* in his *Flora of the British West Indian Islands*. Just before Urban's study, Charles S. Sargent called the trees *Rhamnidium ferreum* in 1891. While such shifting of species from one genus to the other frustrates professional biologists and amateurs by changing names, it is a normal part of the search for the "correct" answers. Because plants do not come with name-tags, people have to try to interpret their relationships with the best information on hand at any given time.

The most widespread use of the species is for its wood. That wood is one of the densest in the world, and this is the heaviest of native woods in Puerto Rico and the United States, with a specific gravity of 1.3 to 1.42 (Record 1926). The sapwood is light brown, and the heartwood is orange brown to dark brown, streaked, fine-textured, and resistant to decay and attack by dry-wood termites. Historically, there were surely larger trees throughout its range, as Sargent (1905) reported Florida plants reaching 30 feet (10 m) tall and 8 to 10 inches (20 to 25 cm) in diameter. Britton and Millspaugh (1962) record the stems to almost 20 inches (50 cm) in the Bahamas, and Adams (1971) indicates that Jamaican trees reach 55 feet (17 m) tall. Perhaps Florida trees were formerly equally as large.

Now throughout much of the range of the species most trees are small. Currently, they are used for posts, veneer, cross ties, and canes (Little and Wadsworth 1964). Schirarend (1987) has provided an anatomical study of ironwood.

In Yucatán, the Maya use the bark and root decoction as a mouthwash to relieve toothache and gum ailments (Steggerda 1943). A decoction of the roots is purgative. In the Turks and Caicos Islands in the southern Bahamas, people use the fruits to make jam and wine (Morton 1968b).

Standing on the top of the tower that penetrates the canopy in the forest at Gumbo

Limbo Nature Center in Boca Raton, Florida, you can actually look down at the flowers and fruits on the trees. The small greenish flowers are visited by a variety of bees and wasps and soon produce fruits. Those small fruits are about 0.25 inches (7 mm) long and do not look tasty or large enough to produce much that might be edible. Perhaps the isolation of people in the Turks and Caicos Islands made everything begin to look edible.

# L

## *Lachnanthes*

(Named by Steven Elliott from Greek *lachne*, wool, *anthos*, flower, because of the pubescent or woolly flowers)

***Lachnanthes caroliniana*.** From  
Institute of Food and Agricultural  
Sciences.

***Lachnanthes caroliniana*** (of Carolina)

dye root; dyer's dilatris (*dilatris* old generic name, from *di*, two, *latris*, servants, an allusion to two small anthers and one large one, USA)

[Carolina] redroot; red weed

spirit-weed

*tali'wa* [*tale'wa*] (Creek)

*wi-ti' ta'ktu* [*tu'ktu*, *ta'ktuwi*] (red root, Catawba)

wool flowers (from the pubescence on their outside)  
yellow tricoma (used by Williams [1837] 1962)

For many years the specific name of this herb, native from Massachusetts to Florida and Cuba, was *tinctoria* (Latin, for dyeing). That name, as did “dyer’s dilatris” and “red root,” arose from the herb’s use as a dye. Porcher (1863) wrote, “The root...[yields] a beautiful dye; hence the name.” However, the story of this wetland herb as a dye plant among indigenous people goes back to William Bartram, who mentioned *tale’wa* as a dye in 1789 (Swanton 1946). Albert S. Gatschet in an unpublished Creek vocabulary from the late 1800s wrote that the name *tali’wa* or *tale’wa* in Creek meant an herb whose roots make red dye for the hair (Swanton 1946). This identity is confirmed by his noting that it was “a plant growing 1 to 2 feet high on sandy soil, with yellow flower. When the roots are fried in oil, the color of the oil changes to a beautiful, brilliant red of the claret hue and is used among other things to make hair oil.”

James Adair wrote in 1775 that the Chicksaws also used the plant (Swanton 1946). Romans ([1775] 1961) made the same report of the color but could never locate the plant. One of Swanton’s (1946) own informants, Jackson Lewis, who originally belonged to a Hitichiti town among the lower Creeks, knew a red dye source by the name *tale’wa*. Swanton (1946) thought it might be the “celandine poppy” (*Stylophorum diphyllum*), but that taxon is outside the range where he reported it, and Moerman (1998) does not list the species.

Millspaugh (1892) recorded: “The root was esteemed as an invigorating tonic by the Aborigines, especially the Seminoles, in whom it is said to cause brilliancy and fearless expression of the eye and countenance, a boldness and fluency of speech, and other symptoms of heroic bearing.” The Cherokee considered the root astringent and used a decoction for sores, for bowel complaints, spitting blood, bloody piles, sore mouth and throat, and venereal disease (Hamel and Chiltoskey 1975). The Catawba used it similarly (Speck 1934). Red root was taken to England in 1812, and subsequently volunteered from seed (Millspaugh 1892). As far away from its native range as the Virgin Islands, Petersen (1974) recommended it be used for muscular strains.

### *Lactuca*

(Linnaeus used the Latin *lactuca*, from *lacteus*, milky, full of milk, referring to the latex)

***Lactuca floridana*.** From Britton and Brown 1898.

*hass* (Arabic)

lettuce (in English by about A.D. 1290; the origin is debated: some derive it from Latin *lactuca* or its adjectival derivative *lactuceae*; akin to Middle English *letuse*, Old and Modern French *laitue*; those words were derived from *lac*, milk, referring to the latex of the plants); *laitue* (French); *Lattich* (German); *lattuga* (Italian); *lechuga* (Spanish); *liatas* (Gaelic); wild lettuce (USA)

*thridax* (Greek)

*wy* (Coptic)

***Lactuca canadensis*** (of Canada)

*agosdagisdi* (*agisdi*, something to eat, *adosdi*, raw, Cherokee)

Canada [wild] lettuce

*hissokcakkó* (*hissi*, leaves, *okcakkó*, green, Koasati)

*odjici'gomin* (Ojibwa)

*soló:pá: #intókifáski* [*soló:pá:ríntókifáski*] (ghosts' thistle, Mikasuki); *yafikcaka:câ* (*yvfekev*, soul or ghost, *vkacv*, thistle, Creek)

***Lactuca floridana*** (of Florida)

Florida lettuce; woodland lettuce

***Lactuca graminifolia*** (with leaves like grass)

grassleaf lettuce (a book name)

Vigorous growing leafy stems before flowering and unexpanded inflorescences may be cooked as a potherb (Fernald et al. 1958). At least the Cherokee ate them historically, and probably others also. Morton (1968b) considered young plants and leaves fairly good when cooked as greens, but not good raw. However, Fernald et al. (1958) considered the greens good enough to use as a salad. Native people used *Lactuca* as a nerve tonic, sedative (Cherokee), pain reliever (Cherokee, Iroquois), and diuretic (Iroquois), to ease or

promote lactation (Ojibwas, Meskwakis), and as a remedy for warts (Ojibwa), pimples, poisonivy rash (Menomini), and other skin irritations, and to stop bleeding cuts (Iroquois) (Vogel 1970, King 1984, Foster and Duke 1990). External use is risky as the plant may cause dermatitis in some.

Early American medical practice considered the plants anodyne, diaphoretic, laxative, and diuretic (Millspaugh 1892). Pollen was in the samples examined by Hogan (1978) so the Glades people also used wild lettuce. It was long believed that the latex, called *lactucarium* (lettuce opium), was a narcotic, but it is only “slightly soporific” (Millspaugh 1892). Cultivated lettuce (*L. saliva*) lacks the bitter sesquiterpene lactones in the wild species (Diggs et al. 1999).

### *Lagenaria*

(Named by Nicolas Charles Seringe, 1776–1858, from Greek *lagenos*, flask, bottle, or Latin *lagena*, a flask; alluding to the most common use of the fruits)

*Lagenaria sicemria* fruit being used as a water container by a Pomeioc woman in North Carolina in the 1580s. From Harriot (1590).

*Lagenaria siceraria* (Greek *sicera*, intoxicating, presumably derived from use of one of the six *Lagenaria* species in making an intoxicating drink) *alahko* (Koasati; they called sphinx moths *alahkobitli*, gourd-dancer)

*bagaña* (Dominican Republic)

calabash (probably from Persian *kharbusa*, melon, or Arabic *qar'ah yabisah*, dry gourd, 1596, English); *calabas largu* (big calabash, Dutch Antilles); *calabaza* [*calabazo*] (Dominican Republic, Puerto Rico, Costa Rica); *calabasse* [*courant, franc, gros, longue, musquée*] (calabash [running, free, big, long, musk-smelling], Houma, Louisiana; Haiti)

*camasa* [*camaza*] (Venezuela)

*candungo amargo* (perhaps “bitter and useless,” Dominican Republic)

*carracho* (Puerto Rico)

*nefku,*

*efepe* [efépe, fepé, hefepe, hefepe-nerkv, hefepe  
*hifipa*] (efépe, gourd, *nefku*, seed, Creek, Muskogee); *hifipí* [hefepe-eele]  
(efépe, gourd, *eele*, seed?, Mikasuki)

[bottle, dipper, etc.] gourd (from Latin *cucurbita* through French  
*gourde*, first recorded in A.D. 1300)

*gourde des pèlerins* [trompette] (pilgrim's [trumpet] gourd, Haiti)

*güicharo* (Puerto Rico)

*güiro* (gourd plant or fruit, Taino, Cuba, Haiti); *güiro cimarrón* (wild  
gourd plant, Cuba); *güiro guyaro* (*guyam* =?, *güiro*, gourd, Cuba)

*i'-ni-i-zhe* (Osage)

*horoto* (Arawak, Suriname)

*ko* (gourd; *akodi*, cup, Biloxi)

*koro* (Carib, Suriname)

*nambiro* [marimbo] (Chiapaneca, Costa Rica, Puerto Rico)

*pehe* (used for rattles, Omaha-Ponca)

*shokshi* (Chickasaw); *shukshi okpulo* (*shukshi* now means watermelon;  
surely a transference from this older use, *okpulo*, bad or spoiled,  
Choctaw); *shukshubok* [shukshihobok] (*shukshi*, watermelon, *holba*,  
resembling, Choctaw); *kochi* (Alabama)

*tä 'mbactu'* (Yuchi)

*tarro* (horn, El Salvador)

*tecomate* (usually *Crescentia cujete*, from *tecomatl*, Náhuatl,  
Salvador); *tecomatillo* (little *tecomate*, El Salvador)

*tol* (gourd with narrow middle, El Salvador, Guatemala)

*totuma* (usually *Crescentia cujete*, El Salvador, Venezuela)

*tula de mate* (tea gourd, Panama)

*wamnuha* [wakmu] (used for rattles, Dakota)

Names of three genera are so badly intermingled in common usage that it is impossible to be sure which applies to *Lagenaria*. Several of the names given in this abbreviated list are of *Crescentia*, but also are often applied to fruits of *Lagenaria*. Even the English word "gourd" may have originally meant some other plant. Gourds were widespread in the New World at the time of European contact, although the confusion of species delayed their identification. De Candolle (1886), for example, did not think they were present when Europeans arrived in the New World.

Historically, there is evidence of gourds among the Carolina Algonquians in drawings labeled "A cheiff Ladye of Pomeiooc" and "Their manner of praigne [praying] with Rattles abowt te fyer [fire]" made by John White in the 1580s (Harriot [1590] 1972). In 1699, Jonathan Dickinson recorded the Jaega near modern Jupiter Inlet using rattles and mixing *casine* in gourds (Andrews and Andrews 1945). The Jesuit priest Jacques Graver found the Houma using *Lagenaria* in 1700 (Thwarts 1896–1901 in Vogel 1970). William Bartram found Seminoles near the Alachua Savanna (now Payne's Prairie) in Florida growing them in 1774 (Bartram [1791] 1958). It was not until Gilliland (1975) began studying the Marco Island artifacts that *Lagenaria* gourds were identified by Hugh Cutler

among the materials left in a burned village about A.D. 1300 (Gilliland 1975). Robinson and Decker-Walters (1997) noted that there is archaeological evidence in Peru, Mexico, and Florida placing the vines there between 7,000 and 10,000 years ago. The Florida record, of probably wild plants, from the Windover Site in Brevard County, was dated at 7,290 years old (Doran et al. 1990).

It is now known that gourds were used by at least the North American tribes Akimel O'odham (Pima), Calusa, Cherokee, Cocopa, Congaree, Dakota, Havasupai, Hopi, Houma, Iroquois, Jaega, Keresan, Navajo, Ojibwa, Ponca, Carolina Algonquians, Seminoles, Tohono O'odham (Papago), and Yuma. The Seminoles and their Muskogean relatives the Houma made dishes, cups, water dippers, and water bottles of them and used them in medicine. Both Seminoles and Houma used them as an analgesic (Speck 1941, Sturtevant 1955). Seminoles call them *hefepe* or *hefepe nerkv* (Creek) or *hefepe eele* (Snow and Stans 2001) and still use the seeds to stop bad dreams. The Ojibwa ate the seeds (Yanovsky 1936). Residents of the Panhandle were still using them to cure "ground itch" when Murphee (1965) talked with them.

In the Caribbean, fruits were used for containers and cooking utensils, but the primary use was as a musical instrument (Liogier 1962). That instrument is called by its Taino name, the *guajey*. Seminoles in William Bartram's time ate the young fruits as do people elsewhere in the Americas (Liogier 1962), but people also use the fruit pulp and seeds as a laxative, and the root as a diuretic for dropsy (Liogier 1974). Syrup from the fruit pulp is a treatment for coughs and asthma (Liogier 1974). Reiser (1979) and Morton (1981) give more details.

### ***Laguncularia*: White Mangroves**

(From Latin *laguncula*, a flask or bottle, in reference to the fruit shape)

***Laguncularia racemosa*. Drawn by  
P.N.Honychurch.**

In the coastal fringes of southwestern Florida lies one of the largest remaining expanses of mangroves in the New World. Lands that are now in the Great White Heron National Wildlife Refuge, the Everglades National Park, and the Ten Thousand Islands region have areas where one may travel in mangroves for miles without seeing another person. Most of the time, traveling in those areas is perilous because of the number of salt-water mosquitoes that vie for a spot to drain your blood. Sometimes the air is so thick with mosquitoes that breathing without inhaling them is difficult.

If you do travel that region and stop occasionally on the drier spots, you might find a mound 2 to 3 m (6 to 9 feet) or even more across, now grown over with other vegetation. Some of those are remnants of where the old charcoal makers plied their trade. Making charcoal in the region was an important local endeavor through the first quarter of the 20th century, and it continued sporadically until the end of World War II. There were even businesses like the Manetta Company along Shark River and the Rutherford Company near Chatham River that were still limping along in the early 1950s (Tebeau 1968).

White mangrove (Florida to Barbados and Panama) is *Laguncularia racemosa*, the name given to it in 1807 by Carl Friedrich von Gaertner, a German physician and botanist in Stuttgart who specialized in seeds. He moved the specific name from *Conocarpus racemosus*, because Linnaeus thought it and *C. erectus* were close enough to be included in the same genus. Gaertner used *Laguncularia* to refer to the fruits. Indeed, the shape of the fruits is the same in both *Conocarpus* and *Laguncularia*, but there are numerous other differences. Linnaeus based his species name on specimens from the Lesser Antilles, but the trees range much farther. White mangrove is known from southern Florida and Mexico (Campeche and Sonora south), through Central America and south to northwestern Peru and northern Brazil. Unlike most American plants, it also occurs in tropical West Africa.

In Florida the Seminoles know these trees as *ahilo: chátî* (white black tree, Mikasuki), *ahilo:csókpi* (spongy black tree, Mikasuki), or *tolastihatî* (*eto*, tree, *Ivste*, black, *hvtke*, white, Creek). While Sturtevant's (1955) informants said they did not use the plants, they did use *Conocarpus* and *Rhizophora*. Perhaps knowledge of these coastal plants was being lost even then by restriction of these people to inland reservations. Alice Micco Snow (Snow and Stans 2001), who has lived her entire life on the Brighton Reservation on the northern end of Lake Okeechobee, does not remember the plants at all.

People living along coasts still know these plants as mangroves, although their modifiers do not always match those in English. Some people just say "mangrove," with *mangel* (Virgin Islands), *mangle* (Sonora, Haiti), *mangue* (Brazil), or *palétuvier* (Guadeloupe, Martinique). To others, they are colored. They may be considered "white," as in *mangle blanc* (Guadeloupe, Martinique), *mangle bianco* (Tamaulipas and Sinaloa south to Panama, Puerto Rico, Dominican Republic), *manglier blanc* (Haiti, Guadeloupe), or *mangue bronco* (Brazil). Others consider them "gray," as *mangle gris* (Guadeloupe, Martinique) and *palétuvier gris* (French Antilles). They are even said to be *mangle amarillo* (yellow mangrove, Cuba, Dominican Republic, Venezuela), *siari paseo* (*siari*, green, *paseo*, mangrove, Yaqui, Sonora), *mangle Colorado* (red mangrove), or *mangle prieto* (black mangrove, Dominican Republic). There does not seem to be a single reason that different colors are applied, and it may depend on what part of the plant

is being stressed. If they say “white” or “green” they are usually talking about the leaves in contrast to those of “black” mangroves (*Avicennia germinans*). Gray and yellow are more often comments on the bark. Red seems to be more a reference to the extracts of tannin made from the plants.

To other people they are false mangrove, *mangle bobo* (idiot mangrove, Puerto Rico), *mangle chaparro* (thicket mangrove), *mangle chino* (curly mangrove, Sinaloa), or *mangle marequita* (ocean mangrove, Costa Rica). I suspect that *bobo* and *chaparro* refer to the problems of navigating through them at high tide.

Like Linnaeus, other people compare them with buttonwoods (*Conocarpus*). To them, they are bastard buttonwood, buttonwood (Panama), or white buttonwood (Florida).

Sometimes people do not distinguish further and have simple names for them. To the Mayo of southern Sonora, they are *moyet*, and to the Seri, they are *pnaacoj*. However, the Seri also note that the white mangrove is *pnaacoj hacáaiz* (harpoon mangrove). In Cuba, it is *patabán* (Taino?), while in South America it is *akira'ë* [*akira*] (Carib, Suriname), *coil* (Guyana), or *furilia* (Arawak, Suriname).

In Mexico, the Aztecs called them *sincahuite* [*cincahuite*] (maybe *centli*, stem, *cuahuatl*, tree, Náhuatl). That word was adopted into modern Spanish and persists in several places (Mexico, El Salvador). In Yucatán and Belize, they are *sak-okom* [*tsakolkon*, *zacalcom*, *zacolcom*] (*sak*, white, *okom*, posts that are the principal support for houses, Maya). People in Belize also call them *but-nuut* (*but*, develop, *nuut*, put something inside something else, Maya). That name too sounds like part of a building.

Costa Ricans consider them the *palo de sal* (salt tree), while in Brazil they yield *tinteira dos mangais* (mangrove dye). Bahamians consider the tree green turtle bough, presumably for making krawls (corrals) to retain these animals.

Like the early settlers in southern Florida, the most common use of the trees has been as a source of charcoal or tannin. The bark contains 10 to 14% tannin (Standley 1920–1926, Morton 1981), and all parts are used for tanning leather in much of coastal Mexico, the Caribbean, and south to Panama. The high tannin content also causes fishermen to dye their nets with the bark (Morton 1981).

Other uses of the wood are for lumber, planks, carts, gates, wooden fences, some construction and repair of farm buildings, flooring, work benches, machinery platforms, railroad ties, piling in areas without teredo worms, posts, tools, houseposts, and bridge lumber (Little and Wadsworth 1964, Uphof 1968, Duke 1972, Liogier 1974). The wood is hard, heavy, strong, attractive, dark greenish brown, with a moderately fine texture, lustrous, and fairly easy to season. However, it is difficult to saw, resistant to drywood termites, and durable in contact with soil.

The high tannin content in the bark also makes it astringent, and it is used as a tonic for fever, a vulnerary to cure skin problems including wounds and ulcers, and to treat scurvy and dysentery (Standley 1920–1926, Uphof 1968, Duke 1972, Liogier 1974, Morton 1981, Coe and Anderson, 1996, Hocking 1997). There is reported antitumor activity attributed to the tannin content (Hartwell and Abbott 1969). According to Hocking (1997), the leaves are boiled for greens in Scandinavia and Great Britain. If he is correct, they must be imported there because the climate will not allow *Laguncularia* to grow there.

In addition to the tannin, the plants contain gum polysaccharides, including galactose, arabinose, rhamnose, galacturonic acid, glucuronic acid, and its 4-Omethyl ether (Pinto et

al. 1993). There are also several minerals in the leaves (Medina et al. 1995) and considerable variation in the foliar waxes, including triterpenoids and alkanes (Rafii et al. 1996).

For thousands of years humans lived beside mangroves and valued them as breeding grounds for fish, crabs, and other food they could easily harvest. As populations grew, values often changed, and mangroves were cleared so that people could live closer to the sea. Until recently, most countries had forgotten the valuable seafood that begins in these marine nurseries. Many countries have now passed laws intended to protect mangroves, but they continue destroying them for other enterprises. As the mangroves are removed or polluted so badly that the seafood either cannot begin growing there or is so poisonous humans cannot eat it, many still argue that mangroves are nothing but mosquito-breeding grounds.

There are so few old, large mangroves remaining in the world now that most of us cannot imagine how large the trees can grow. In 1999, I visited the mangrove preserve on the outskirts of Guayaquil, Ecuador, where shrimp farming is steadily encroaching on the old forest. While the remaining trees were large, none was nearly big enough to have been used to make the dugout canoes that lined the village bank. Some of those canoes were made from trees at least 1 m (3 feet) in diameter. Craighead (1971) recorded mangroves that size growing in southern Florida until 1960 when Hurricane Donna toppled trees with diameters of 1.2 m (4 feet). By the time I saw the path of that hurricane in the early 1970s, those fallen tree trunks mostly were covered over with mud, water, and herbs.

While wandering around in mangroves in south-western Florida, I have often wondered what those old forests were like. Sometimes during those walks through the peaceful shade below mangrove canopies, mangrove skippers (*Phocides pigmalion*) would fly past. The ethereal iridescent turquoise blue stripes on their hind wings flickered like the ghosts of those old fallen trees, reminding me of ancient forests I would never see.

### *Lantana*

(Virgil, 70–19 B.C., called a plant *lenta viburna*, flexible viburnum; now reflected in *V. lantana*, and reapplied by Linnaeus to these plants; see also *Lantana*: Button sage, next entry, and *Viburnum*)

*Lantana depressa* (low, pressed down)

(=*L. ovalifolia*)

big sage (Bahamas)

lantana (Florida)

*sypeyv* *lakko[rakko]* (*sypeyv*, the mythical plant, *lakko*, big, Creek);

*shapeye-choobe* (*choobe*, big, Mikasuki)

Linnaeus ([1753] 1957) included seven species in *Lantana*, with only one from Africa. Indeed, most of the 150 species in the genus are American (Mabberley 1997).

A decoction is used as a drink or bath for measles in the Bahamas (Ayensu 1981, Morton 1981). Since both *L. camara* and *L. involucrata* (see *Lantana*: Button Sage) are also called “big sage,” uses of the three are likely interchanged. Indeed, Snow and Stans (2001) list *sypeye* or *shapeye* as *Poly gala*, but say that *sypeyv rakko* is stronger for the same purpose. So, not only is more than one *Lantana* involved, but a second genus. See *Polygala* for further details.

*Lantana camara* contains triterpenoids (lantadense) and verbascoside, an inhibitor of protein kinase C, and can be poisonous (Nellis 1997). Distribution of these poisons in other species is poorly known.

### ***Lantana*: Button Sage**

(See preceding entry for etymology)

An aromatic shrub called button sage (Florida, Puerto Rico) grows behind the dune crest from Cape Canaveral in Brevard County around the southern tip of the state and up to Pinellas County in the Tampa Bay region. Typical of common names, the plants are not sages (genus *Salvia*) but are actually a lantana (*Lantana involucrata*). To make matters more confusing, some people also call these fragrant bushes oregano (genus *Origanum*). This apparently lax use of names results from similarities with true sages and

***Lantana involucrata*. Drawn by  
P.N.Honychurch.**

oreganos (e.g., zygomorphic flowers, aromatic foliage) and differing philosophies of classification.

Both “lantana” and “sage” are derived from ancient names dating back to the classical periods of Rome and Greece. “Oregano,” on the other hand, appears to be from the 13th century, and had other names in older Greek.

English, Spanish, and French speakers consider these shrubs sages. In English, they are big sage (Bahamas), bitter sage (Caymans), black sage (Bahamas), dark sage

(Bahamas), fine-leaf sage (Bahamas), rock sage (Barbados), roundleaf sage (Caymans), sage (Virgin Islands), teeny-weeny sage (Bahamas), white sage (Barbados), and wild sage (Bahamas, Puerto Rico). In Spanish lands they are *salvia santa* (holy sage, Guatemala). People speaking French say *baume blanc* (white sage, Guadeloupe, Martinique), *petit baume* (little sage, Guadeloupe, Martinique), and *sauge* (sage, Guadeloupe, Martinique).

The word “sage” in English traces its origin to the Latin *salvia*. From that language, *salvia* became *salute* in Old English, *save* or *sauge* in Middle English (about the 4th century A.D.) and ultimately sage. Since English is a Germanic language, it is not surprising to find a similar alteration of the original *salvia* in them. From the Latin, the word became *salbeia* or *salveia* in Old High German, and then *salvie* or *selve* in Middle Low German. Today, it is *selie* in Dutch and *Salbie* in German. In Romance languages, the evolution followed a similar route, staying *salvia* in Italian and Spanish, but becoming *sauge* in French and *salva* in Portuguese. In spite of the 2000 or so years that these words have been evolving, the same exact meaning of *salvia* (to save or preserve, because of medical usage) is retained in English. Not only did the word have that meaning in the beginning, but we now know that many of the spices, including mints, are antibacterial (Chen et al. 1985, Sow et al. 1995, Tassou et al. 1995, Wen et al. 1995, Billing and Sherman 1998, Imai et al. 2001). However, the complete reliance on spices to protect from infection in foods will never become a reality because of evolving new virulent strains (D’Aoust 1994), and differential impact on microorganisms (Beddows et al. 2000, Ismail et al. 2001).

Those who think *L. involucrata* is like oregano say *orégano* (oregano, Tamaulipas) and *orégano de monte* (wild oregano, Nicaragua). The word “oregano” (from the Greek *oros*, mountain, plus *ganos*, brightness, joy, or pride), first was *oreiganos*, and later was used in English ca. A.D. 1265. Originally, the word applied to several species of mints in the genus *Origanum* (See *Bacopa*: Water-hyssop), including *O. vulgare* and *O. marjorum*. Before that *Origanum* was called *dictamnion* by the Greeks, or *artemidion* after Artemis (goddess of the chase). She could wound with her poisoned arrows and then cure the wound with *O. dictamnus* of Crete (Baumann 1993).

In spite of its common names, button sage is a *Lantana*. That word was the ancient Latin name for *Viburnum* and is now reflected in *V. lantana*. Between the 13th and 14th centuries, the spelling was *lentana*, but it changed before 1590 to *lantana*. In Sicilian, it remains *lantanu*, and the spoken Latin originally was *lentaginem*, from *lengus*, pliant (from flexible viburnum, *lenta viburna*, of Virgil, 70–19 B.C.). Linnaeus applied the name to American plants to create the

modern application. There are 150 species in *Lantana*, mostly native throughout tropical America, but with a few in southern Africa (Mabberley 1997). The best-known species is *L. camara*, one of the most widely used of the medicinal species, which is also an aggressive weed. The species is a weed in Florida and other parts of the United States, including Hawaii, where insects were introduced about 1902 for minimally successful biological control (Julien and Griffiths 1998), New Caledonia, South Africa (Cilliers and Naser 1991), and elsewhere. This is the most-studied species in the genus and contains toxic triterpenoids (the lantadenes) (Achhireddy et al. 1985, Sharma et al. 1989, 1990, 1991, Barre et al. 1997, Misra and Laatsch 2000), verbascoside (an inhibitor of protein kinase C; Herbert et al. 1991, Taoubi et al. 1997), and phytotoxins (Jain et al. 1989). This

and other species 'also contain novel compounds (Singh et al. 1990, Abeygunawardena et al. 1991, Takeda et al. 1998, Muhayimana et al. 1998).

Button sage (*L. involucrata*) is native from southern Georgia and Florida, along the Gulf Coast states to Texas and in the Bahamas and the Caribbean from Cuba to Barbados. The species grows in Guatemala, Belize, southern Mexico (Campeche, Quintana Roo, Yucatán), and the Galapagos Islands. In those areas, it has yet other common names, and most of them make other references to medical uses. These names include *cariaquilla de Santa María* (Saint Mary's *caraquilla*, Puerto Rico) and *cariaquito encarnado* (red *cariaquito*). In Venezuela, *cariaquito* is a generic name for *Lantana*, with *L. alba* being *cariaquito blanco*, *L. camara* is *cariaquito Colorado*, and so on. There are also the names *chiligue* (El Salvador), *cinco negritos* (five little black ones, El Salvador), *confite* (confidence, Sinaloa), *confituria blanca* (white confidence, Mexico), *cuasquito oloroso* (fragrant *cuasquito* Nicaragua), *doña sanica* (healthy lady, Dominican Republic), *doña Anita [Ana]* (lady Anita [Ana], Dominican Republic), *filigrana cimarrona* (wild filigree, Cuba, Puerto Rico), *hierba de la sangre* (blood herb, Cuba), *té de costa* (coastal tea, Cuba, Puerto Rico), wild balsam (Bahamas), and wild mint (Jamaica).

Other names given to the plants have obscure references. There seems to be nothing similar to peony (*Paeonia*, Paeoniaceae), but in Mexico it is called *peonía* (Tarahumara, Chihuahua) and *peonía Colorado* (red peonia, Tamaulipas). In addition, in Mexico, *L. involucrata* is known as *tarepe* (Michoacán) and *sikilha'xiu [zicilhaxiu]* (*sikil*, *Cucurbita* seed, *ha'*, water, *xiw*, herb, Maya, Yucatan).

The most unexpected of all the common names of *L. involucrata* is *cerise* (cherry in French and Spanish, Hispaniola). There is nothing to me that resembles a cherry (*Prunus cerasus*, Rosaceae). To make it more intriguing, that is also the common name widely given to *Momordica charantia* in the Caribbean. In Haiti, this name may be spelled as *sorrosie* and *assorossie*, while in Jamaica and the Cayman Islands, it is written *serasee* or *cerasee*. My Jamaican students all pronounced it as "ser-see" and were astonished at the spelling in Caribbean herbal shops. The only possible connection that I can imagine between these plants is that they are medicinal. Perhaps the fact that the "medicine" as a tea also tastes terrible contributed to both being called by the same name.

*Lantana involucrata* has been used as a tea and bath for measles and chicken pox, to relieve itching skin (Ayensu 1981), to control high blood pressure (Honychurch 1987), against irregular menstruation (Morton 1981), and to aid parturition (Ford 1975). It is also considered effective if boiled with sugar and used as a drink to bring out the spots of measles and chicken pox (Ayensu 1981). In Mexico, pieces of leaves or stems have been put in the ears as a "cure" for deafness (Standley 1920–1926). Throughout much of its range people consider a leaf infusion sudorific and diuretic, and the pounded leaves in water as emetic. Boiled with *Serjania subdentata* (Sapindaceae) it "purifies blood" and reduces fever (Morton 1981).

Chemically, the species is similar to *L. camara* and contains lantanine, which has qualities similar to quinine (Liogier 1974, Ayensu 1981). Both are aromatic and *L. camara* is said to have 0.22% essential oils (Ayensu 1981). Other species have been studied more recently and have been shown to be antimicrobial (Saleh et al. 1999), anti-inflammatory, analgesic, and antipyretic (Forestieri et al. 1996), and to have antithrombin activity (O'Neill et al. 1998). *Lantana trifolia* also has been shown to be antimicrobial (Rwangabo et al. 1988). In spite of its poisonous chemicals, some cultures still eat the

fruits (Herzog et al. 1994, Taoubi et al. 1997). If *L. involucrata* indeed has the same basic chemical spectrum as *L. camara*, many of the folk uses, while dangerous, may prove effective.

One beautifully ironic study has shown that the aqueous leachate of *L. camara* kills water hyacinth (*Eichhornia crassipes*) (Saxena 2000). If *L. involucrata* does the same, it would be a lovely bit of human justice to turn native and exotic Lantanas against the alien pest water hyacinth. *Eichhornia* alone has cost the taxpayers of Florida millions of dollars annually for decades. It would be true fair play—and a better use of taxes—to turn one alien plant against another.

### *Laportea*

(Charles Gaudichaud-Beaupré, 1789–1854, named the genus for Frangois L. de Laporte, 1810–1880, Count of Castelnau, an entomologist who collected plants in Florida between 1843 and 1847)

#### *Laportea canadensis* (from Canada)

*Brennpflanze* (stinging plant, German)

Canadian wood-nettle [woodnettle, nettle of the woods] (“nettle” from Old English *netele*, *netel*, *netle*, based on an Old Teutonic name for the genus *Urtica*, applied by about A.D. 705); nettle patch; [Canada, stinging] nettle; woodland-nettle

*ha'-do-ga* (a sacred plant; fibers used to weave sacred rush mat case for the *wa-xo'be* or Sacred Hawk; *mon-hin wa-xton ha-do-ga (mon-hin*, grass, Osage)

*hatka holhpa* (*hatka*, man, but implying a Choctaw, *holhpa*, blister, Choctaw; also used for a stinging caterpillar)

*mason* (Cree, Menomini, Ojibwa); *mason* (Strachey wrote this *makuhsaan* in [1612] 1953, Powhatan, Virginia); *masana* (Fox, Shawnee)

*stvtvlálv* (Muskogee)

Although none of my sources lists the common name “stinging nettle,” that is the one I was taught when growing up in western Kentucky. This is a plant of forested lowlands, often growing on floodplains. No one there had ever heard of “wood-nettle” or “Canada nettle.” We also knew that there were two kinds of “stinging nettle,” the other one the weedy upland *Urtica dioica*. We tried to avoid both, but sometimes failed. Once when leading a class field trip as a teaching assistant to an undergraduate professor, I accidentally walked deep into a patch of *Laportea* before they penetrated my Levis. Although I stopped everyone and we backed out, those wearing shorts had tears running down their cheeks as we left.

Lewis and Elvin-Lewis (1977) record that the stinging plant hairs of both nettles contain histamine-like substances. These compounds are held in the bulbous tips of the hairs that break upon puncturing the skin to release the irritant chemicals. Not surprisingly, indigenous people had remedies for the rash caused by nettles. The Potawatomi relieved the rash with the juice of jewel weed (*Impatiens capensis*) (Smith

1933, Vogel 1970). The Rappahannock treated nettle stings with urine or salt and water (Vogel 1970).

Use of *Laportea* fibers goes back to the Hopwellian Cultures where Whitford (1941) has identified fabrics woven of them. The fibers also appear as cords in prehistoric cave shelters in Arkansas, Kentucky, and Tennessee (Whitford 1941). Historically, at least the Abenaki, Fox, Menomini, Meskwaki, Sauk, and Ojibwa used fibers extracted from the stems to make baskets, twine, bags, cords, and sewing fibers (Whitford 1941, Uphof 1968, Moerman 1998). Those fibers are said to be 50 times as strong as the same diameter of cotton (Uphof 1968).

Among Muskogean people, only one tribe is noted as using the plants. According to Speck (1941), the Houma applied a decoction to lower fever. No other people is recorded as using the plant in this way and the genus does not appear in Porcher (1863) or Millspaugh (1892).

Several other eastern tribes used the plants for other purposes. The Iroquois used a decoction to counteract "love medicine," an infusion of roots to ease childbirth, and to treat tuberculosis (Moerman 1998). The Meskwaki used the root to treat incontinence and as a diuretic (Moerman 1998), seemingly diametrically opposed applications. The Ojibwa also used an infusion of roots to treat urinary problems (Hocking 1997, Moerman 1998).

### *Lasiacis*

(Greek, *lasios*, shaggy, woolly, *akis*, tip, referring to the tuft of wool at the apex of the spikelet)

*Lasiacis divaricata*. a. Habit, b. First and second glume, c. Sterile lemma and palea. d. Fertile lemma and palea. e. Pistil and lodicules and stamen . f.

Young spikelet and mature spikelet . g.  
Caryopsis. *Drawn by Priscilla Fawcett.* From Correll and Correll  
1982.

*Lasiacis divaricata* (spread apart, alluding to the branches)  
*alcarrizo* (reed, from Latin *carex*, a sedge, Hispaniola); *carrizo* (cane, Hispaniola, Honduras)

*bambou marron* (wild bamboo, Hispaniola); wild bamboo (Florida; see Small 1933); *petit bambou [calumet]* (little bamboo [pipe], Guadeloupe, Martinique)

*calimete* (variant of *calumet*, Hispaniola); *calumet* (pipe, French, Guadeloupe, Martinique; reed (from Latin *calamellus*, Greek *kalamos*, now “straw” or “pen,” from quill or reed pens, in English, through *haulm* from Middle and Old English *healm*, Latin *culmus*, “stem”)

cane-grass (Bahamas); wild cane (Bahamas)

*mehensit* (little reed, Maya, Yucatan)

*pitillo de monte* (wild little whistle); *pito de bejuco* (vine whistle, Cuba)

*sit [zit]* (cane or reed, usually used for *Arundo donax*, Maya, Yucatan)

small-cane [smallcane] (Florida)

tibisee (Florida, Bahamas); *tibisi* (name for reed, *Phragmites australis*,

Taino, Cuba); *tibisi chico* (little reed, Cuba)

Wild bamboo (*Lasiacis divaricata*) is the smallest of the native bamboo-like grasses in southern Florida. *Lasiacis* was created in 1864 as *Panicum* sect. *Lasiacis* by German botanist August H.R.Grisebach. Later, in 1910, it was moved to generic rank by A.S.Hitchcock. The small plants (2 to 4 m; 6 to 12 feet) grow in southern Florida, the Bahamas, the West Indies from Cuba to Barbados, and from Baja California to Veracruz, and south to Peru and Argentina. In much of its range, uses of the grass overlap with uses of the other plants with the names “cane” and “reed” (see *Arundinaria*, *Phragmites*).

While it usually grows in hammocks, *Lasiacis* is not immune to water level and habitat loss changes. Although the species ranges from the southernmost Florida Keys to Cape Canaveral in Brevard County on the east and Fort Myers in Lee County on the west coast, now it is confined to tiny fragment sites. Most of the coastal regions where it grew are housing developments. We no longer use it, and we are about to lose it.

### *Leitneria*

(Named for German physician Edward Frederick Leitner, 1812–1838, who was killed in Florida during the first Seminole War)

***Leitneria floridana*.** From Sargent  
1905.

***Leitneria floridana*** (of Florida)  
corkwood

This monotypic genus is endemic to the southeastern United States. There are Eocene fossils from London, England, that have been identified as this (Mabberley 1997), but Cronquist (1981) has questioned their identity. The single species was named by Alvin Wentworth Chapman (1809–1899), author of the *Flora of the Southern United States* in 1860. He described the genus and species in the first edition of that flora, and then went on to publish a second edition in 1883, and a third in 1897 (Correll and Johnston 1970).

Florally, the plants are so unique that George Bentham and Joseph D. Hooker (1817–1911) segregated them as the family Leitneriaceae in 1880 (Cronquist 1981). The modern view, however, based on molecular genetics, anatomy, and serological studies, is that they are members of the Simaroubaceae with flowers reduced for wind pollination (Judd et al. 2002).

These trees grow in isolated areas in the Bootheel area of southern Missouri (Butler, Ripley, Dunklin Cos.), Arkansas, Texas (Brazos River near Columbia), Florida (Appalachicola area), and southwestern Georgia (Sargent 1905, Fernald 1950, Steyermark 1963, Correll and Johnston 1970, Jones and Coile 1988).

Wood has been used for fishing corks (it is lighter than cork), floats for nets, and stoppers (Sargent 1905, Hocking 1997, Mabberley 1997). The plants are so rare they are considered threatened in Florida (Coile 2000), but Ward (1979) did not consider current harvesting for these purposes to be a threat.

### ***Lepidium***

(Greek classical name from *lepídon*, a little scale, an allusion to the flat fruit)

*biolair-Fraing* (French cress, for *L. sativum*, Gaelic)

*Kresse* (from Latin *cressa*, German)

*lepidio* (Spanish for *L. latifolium* from 1542); *lepidio maggiore* (big little-scale, Italian for *L. latifolium*, from 1551)

*markkarse* (field cress, Norwegian for *L. campestre*)

*matkarse* (food cress, Norwegian for *L. sativum*)

*mostardina* (little mustard, Italian)  
*passerage* (cress, French for *L. latifolium*, from 1550)  
*pepercruyt* (pepper herb, Dutch for *L. latifolium*, from 1549);  
*pepperwurt* [*pepperwoort*, *pepperwort*] (Dutch for *L. latifolium*, from 1500s); *Pfefferkraut* (pepper herb, German for *L. latifolium*, from 1542)  
*vollkarse* (wall cress, Norwegian for *L. heterophyllum*)

***Lepidium virginicum*** (of Virginia)

bird's pepper; poor man's pepper; Virginia pepperweed [Virginia pepperweed]

***Lepidium virginicum*.** a. Habit of upper part of plant. b. Young plant, showing basal and cauline leaf forms. c. Flowers, top and side views, d. Silicles, mature and immature, e. Seed. Drawn by Regina O. Hughes. From Reed 1971.

boiled-seed bush  
*cresor* (cress, Houma, Louisiana); *cressón* (big cress, Puerto Rico);  
*cresson* [*a*, *de*] *savane* [*alénois*, *danois*, *savage*] (savanna [awl, Danish, wild] cress, Guadeloupe, Martinique, Haiti)  
*culantrillo* (little coriander, El Salvador)

*cupapayo* (perhaps based on the Zoque name *cupapé*, or Mayan *k'opte'*, with a hard center, the name for *Cordia*, although any relationship between this herb and that tree is obscure, Yucatán)

*hashshan* [*haashan*, *hashan*] (Chickasaw); *tukáskénv* (Muskogee)

*julipliergue* (strong reprimand, presumably an allusion to the spicy taste, Guatemala)

*lentejilla* [*lentajilia*, *lentejuela*, *lentequilla*, *antejuela*, *antejuelilla*] (little lens, Texas, Chihuahua, Mexico, Guatemala, Puerto Rico)

[*hierba*] *mastuerzo* [*mastuerce*, *mastuerco*] (*nasturtium*, Yucatan, Belize, Cuba, Dominican Republic, El Salvador, Guatemala, Puerto Rico); *maltuerce* (Nicaragua)

*mecheche* (*che'*, plant, Maya, Yucatan); *mixixe* (Mayan?, Guerrero)

*mostacilla* (little mustard, New Mexico)

*panalillo* (a name usually given on the north-western coast to *Thouinidium decandrum*, Sapindaceae, Mexico)

*passerage de Virginie* (Virginia cress, French Antilles)

[American, Virginia, wild] pepper-grass [pepperbush] ("pepper-grass" applied ca. 1475 to *Lepidium sativum*, because of the spicy taste of the fruits, subsequently to other species; USA, Bahamas, Barbados, Puerto Rico)

*perejil de la tierra* (wild parsley)

*put xiu* (*put*, papaya [*Carica papaya*], *xiw*, herb, Maya, Belize, Yucatán)

*putcan* [*putkan*] (*put*, papaya, *kan*, yellow; the reference to papaya is because the odor of the mashed fruits resembles that plant, Maya, Yucatán)

*sabelección* (knows the lesson, Cuba)

*sacabé* [*sakbé*] (*sak*, white, *bé*, road, probably given because it grows along roads and pathways, Maya, Guatemala)

tongue-grass [tonguegrass] (northeastern USA)

Virginia cress (South Carolina, fide Porcher 1863); *Virginiakarse* (Virginia cress, Norwegian)

wild cress (Barbados)

Europeans were well acquainted with *Lepidium* by the time the New World was discovered. Indeed, classical authors Dioscorides (A.D. 40–80), Galen (A.D. 129–?200), and Pliny (A.D. 23–79) discussed *L. latifolium*, and Fuchs (Meyers et al. 1999) also detailed three other species. Culpeper (1653) wrote of *L. sativum*: "This is very successful for the sciatica, gout, and pains in the joints...it also amends deformities or discolorings of the skin, and takes away scars, marks, scabs and burns. The juice is given in ale to procure women a speedy delivery in travail."

In addition to the medical applications listed by the classical authors, Fuchs added, "*Lepidium* has the power to thin thick and viscous fluids. Accordingly, it is a culinary herb and suitable for pickling" (Meyers et al. 1999). The Cherokee agreed and ate young *L. virginicum* plants either boiled or fried (Moerman 1998). Porcher (1863) added, "It is suitable to be used in winter and early spring salads, but is far less in request than some

of the other cresses.” Hedrick (1919) did not list this edible species, although he included six others.

Among the Muskogean people, the Houma took a mixture containing this and other herbs with whiskey to relieve tuberculosis (Speck 1941). Muskogean neighbors and their subsequent allies, the Cherokee, produced a poultice to help cure blisters and to ease croup, and made a remedy to give sick chickens to make them lay eggs (Hamel and Chiltoskey 1975). The Menomini used an infusion of the plant to wash the rash from poison ivy (Moerman 1998).

Foster and Duke (1990) record that the herbs were used to treat scurvy in addition to the applications noted among the indigenous tribes. Hocking (1997) says that the Mayas made a root decoction with *Aloe barbadensis* root and treated coughs and colds with it. The Maya have adapted the alien *Aloe* into their pharmacopoeia. Elsewhere in Mexico, a tea is made from *Lepidium* flowers and leaves to relieve digestive problems (Morton 1981). People from Mexico and Guatemala to Coro in Venezuela (Martinez 1969, Ford 1975, Morton 1981, Gupta 1995a) use the herbs in other applications. However, Foster and Duke (1990) warn that *Lepidium* may cause skin irritation and blisters.

### *Lespedeza*

(Named after Vincente Manuel de Cespedes, the Spanish Governor of East Florida between 1784 and 1790, who sponsored Frenchman Andre Michaux’s exploration of the region; Michaux intended for the name to be “*Cespedeza*” but it was misspelled in the printed book as *de Lespedez*, cf. Taylor and Norman 2002)

***Lespedeza capitata*** (with flowers in heads)

[bush, dusty] clover

*parus-as* (*parus*, rabbit, *as*, foot, Pawnee)

roundhead lespedeza

*te-hunton-hi nuga* (*te*, buffalo, *hunton*, belly, *hi* plant *nuga*, male, Omaha-Ponca)

The species was named by Michaux in his *Flora Boreali-Americana* (Flora of North America) of 1803. *Lespedeza* is now a genus of 40 species, growing in temperate regions of North and South America, and also in Asia and Australia (Mabberley 1997).

Gilmore (1919) found the people of the Missouri River region had used these plants. Its name in Omaha-Ponca considers it a “male,” while at the same time comparing it with *Amorpha* (see *Amorpha*: Lead Plant), which they called *te-hunton-hi miga* (female buffalo belly plant). These two tribes used the stems of *Lespedeza* as they did *Amorpha*—as a moxa, where one end was stuck to the skin and the other burned until it “cured” the ailment by scorching the patient. The “cure” was for rheumatism and neuralgia. The Meskwaki of Iowa considered the root an antidote for poison. The Comanche made a tea from the leaves (Moerman 1998).

In Mexico, *L. capitata* is used for kidney problems and anuria, including nephrosclerosis, oliguria, and uremia (Hocking 1997).

*Leucothoe*

(Roman writer Ovid, 43 B.C.–A.D. ?17, identified *Leucothoe* as the daughter of King Orchamus of Babylonia; she was one of the many loves of Apollo)

*Leucothoe racemosa*. From Britton and Brown 1897.

*Leucothoe axillaris* (in the “armpit,” or having the flowers in the angle between the leaves and stems)

coastal dog-hobble [coastal doghobble]

drooping leucothoe (a book name)

fetter bush (“fetter” from Old English *feter*; with cognates in Dutch *velter*, Swedish *fjdltrar*; in English since about A.D. 800. Then, as now, it means a chain or shackle of some kind around the feet of humans or animals. No indication of when it was applied to these bushes has been found, but the allusion is to the symptoms of animals being poisoned by eating the branches.)

*Leucothoe axillaris* was described by J.B.Lamarck in 1783 as an *Andromeda*. At almost the same time, Thomas Walter described the same plants under the name *Andromeda catesbaei* in his *Flora Caroliniana* of 1788. The name proposed by Lamarck is used because it preceded the name used by Thomas by some 5 years.

It was not until 1834 when David Don (1799? 1800–1841) realized that these plants belonged in a new genus and created *Leucothoe*. Subsequently, other regions of the world were explored and this ericaceous genus now has eight species in North America, Japan, and the Himalayas (Mabberley 1997). There are five species endemic to North America, some of which are cultivated as ornamentals.

Considering the potent chemicals in the Ericaceae, it should not be surprising that these plants were used by indigenous people. This species contains andromedotoxin (Perkins and Payne 1978) and is as toxic as *Kalmia* (which see).

The Cherokee used an infusion to treat pain, rheumatism, and itch, as a stimulant, and to treat mange in dogs (Hamel and Chiltoskey 1975, Moerman 1998). That is the only tribe known to have used these shrubs, but Hocking (1997) said that they were “used as errhine” (increase nasal mucous) among “Indians.”

No mention of the plants was made by Porcher (1863) or Millspaugh (1892).

*Liatris*

(Derivation of the name is unknown, and J.C.D.von Schreber, 1739–1810, left us no clue; could it be possible that he used the Gaelic *liatrus*, spoon-shaped, as an allusion to the sometimes bulbous roots?)

*aontashe* (Omaha-Ponca)  
 blazing star [blazingstar]  
 button-snakeroot  
 gay feather [gayfeather]  
*kahtsu-dawidu* [kahtsu-rawidu] (*kahtsu*, medicine, *dawidu* or *rawidu*, round, Pawnee)  
*makan-sagi* (hard medicine, Omaha-Ponca)

*Liatris chapmanii* (named for Alvin Wentworth Chapman, 1809–1899, who wrote the first flora of the southeastern United States)

blazing star  
 Chapman's gayfeather (a book name)  
*ecjomahi* (*id*, deer, *im*, its, *aahi*, potato, Mikasuki)

*Liatris graminifolia* (with leaves like grass)  
 backache-root (North Carolina)

*Liatris gracilis* (slender) (= *Liatris laxa*, *L. laevigata*)  
 button snakeroot (Florida in 1911); rattlesnake master (Florida)  
*'comvhv* [*comahâ*, *ico imaha*, *i'djo maha*, *ijo maha*, *itimahi*, *itco imaha*] (*eco*, deer, *em*, its, *vhv*, potato, Creek, Muskogee); *i:cima:hî* [*eeche* 'make, *iicimaahi*] (*ici*, deer, *im*, its, *aahi*, potato, Mikasuki); *issim-ahi* (*issi*, deer, *im*, its, *ahi*, potato, Chickasaw)

*Liatris tenuifolia* (slender-leaved)  
 backache root  
 [slender-leaved] blazing star  
 deer bowl (Florida)

*Liatris* is a genus of 43 species endemic to eastern North America, including northeastern Mexico (Gaiser 1946, Mabberley 1997). As Ajilvsgi (1984) and Diggs et al. (1999) pointed out, one of the generic common names is "button-snakeroot," derived from the old use of the cormlike roots in treating snakebite. That name is also applied to other plants used to treat bites (see *Eryngium*). The application may date to prehistoric people like those at the Ozark BluffDweller site in Arkansas. There Gilmore (1931) identified remains of two species and commented on *L. squarrosa* that "This was probably used

medicinally, as it is still employed by Indians.” Earlier (1919) he had learned of *Liatris* use among the OmahaPonca and Pawnee.

Swanton (1928) reported the Creeks using *Liatris* sp., and Taylor (1940) found their relatives the Koasati using *L. acidota*. Spoehr (1939) found the Creeks using *L. gracilis*, as did Sturtevant (1955) with the Miccosukee. Bennett (1997) found the people on the Big Cypress Reservation where Sturtevant worked using *L. chapmanii*. Given the similarity of several *Liatris* species, more than one may be used in any particular area. Several other species are used by various people, including the Blackfoot, Comanche, Kiowa, Koasati, Lakota, Meskwaki, Ojibwa, OmahaPonca, Pawnee, and Tewa (Moerman 1998).

The Seminoles use the roots for “Cow Sickness” (chest pain, digestive upset, diarrhea), “Deer Sickness” (pain in limbs, especially joints, swelling, bad dreams), and “Bird Sickness” (diarrhea, vomiting, appetite loss) (Sturtevant 1955). Part of their treatment is a decoction of this plant and several others used externally for rheumatic joints. *Liatris chapmanii* also is used to treat Deer Sickness, constipation, and asthma, and is used in other herbal mixtures (Bennett 1997). The Chickasaw use the root as a medicine to treat swelling (Munro and Willmond 1994).

Hocking (1997) noted that *L. chapmanii* contains chapliatrin, an antileukemic germacranolide compound, and that extracts show *in vitro* inhibition of human carcinoma (Kupchan et al. 1973). He also said that *L. gracilis* contains substances active against lung cancer, leukemia, and lymphocytic anemia. In his master’s thesis, Hocking found that *L. tenuifolia* contains chapliatrin, spicatin (a sesquiterpene cytotoxic lactone), and ecuparin.

### *Licania*

(Misspelled anagram of the Galibi name *caligni*, given to a French Guiana plant by J.F.Aublet; see Prance 1970)

*Licania michauxii* Drawn by  
P.N.Honychurch.

***Licania michauxii*** (named by Ghillean Prance to commemorate André Michaux, 1746–1802, French botanist who lived some years in the United States)

*ayekche-chobee* (*ayekche*, medicine, *chobee*, big, Mikasuki)

gopher-apple (“gopher,” as *gaufre*, honeycomb, was applied to burrowing animals by French colonists because their dens are like “honeycombs”; “gopher” was the name already established for the tortoise that Linnaeus called *Gopherus polyphemus* in 1759; fruits are eaten by the gopher tortoise)

*lucv-huehkv enhompety* (*lucv-huehkv*, gopher turtle, *em*, its, *hompety*, food, Creek); *apaahoshe emempeeke* (gopher turtle food, Mikasuki)

maiden-blush [-rose] (in use for these plants by 1760; an allusion to the pink tinge on the white fruit)

*obí:hosimimpí* [*abah’ha shemembe*] (wolf’s food, Mikasuki)

*yahami:láyka* [*yamelikv*] (*yvhv*, wolf, *em*, its, *vlicv*, sickness brought on by, Creek)

Aublet created the genus *Licania* in 1775, and some of the Amazonian and Guianese species are large trees. Therefore, it was a surprise when Prance (1970, 1972) concluded that *L. michauxii* was part of the genus. *Licania* contains 193 tropical species, with 1 in Africa, 2 to 3 in Asia, and the rest in the Americas (Mabberley 1997).

Hogan (1978) found pollen from *L. michauxii* at the pre-Columbian village site at Fort Center on Lake Okeechobee (Sears 1982). When Sturtevant (1955) worked on the Big Cypress Seminole Reservation, they still were using the plants. Fruits are edible (Morton 1968b), but to me taste like a new plastic shower curtain smells. Sturtevant (1955) found the species used in medicines to treat “Wolf Sickness” (vomiting, stomach pain, diarrhea, frequent urination), chronic sickness, insanity, and to ease childbirth. Bennett (1997) found similar applications to stomach pains and asthma. His informants and Snow and Stans (2001) indicated that it was most important in purification ceremonies following death.

No chemical studies have been made of this *L. michauxii*, but others are known to contain a variety of bioactive compounds. Among those chemicals are flavonoids, lupanes, terpenoids, and triterpenoids (Bilia et al. 1996, Braca et al. 1999a,b, 2000).

### ***Licaria***

(J.F. Aublet named the genus in 1775 with *licari*, a French Guiana Carib name)

***Licaria triandra*** (with three-stamens)

*bois fourmi* (ant tree, Martinique)

*cigua gorrita* (little alien *cigua*, Dominican Republic); *cigua prieta* [*sigua prieta*] (black *cigua*; *cigua*, a laurel, Taino, Dominican Republic)

Gulf *licaria* (USA, Puerto Rico)

Gulf misanteca (misanteca, probably from Latin *minus*, fewer, Greek *anthus*, flowers, USA); [*palo*] misanteco [*misanteca*] (*misanteca* [tree], Puerto Rico)

*laurel [blanco, de Jamaica, de loma]* ([white, Jamaica, hill] laurel, Cuba); *laurier jaune [sassafras]* (yellow [sassafras] laurel, Haiti)

*lebisa [levisa]* (usually a name given a stingray, *Dasybatus torrei*, Taino?, Cuba, Puerto Rico)

[pepperleaf] sweet-wood [sweetwood] (Florida, Dominican Republic, Jamaica)

Olaf Swartz named these trees *Laurus triandra* in 1788. It was not until 1937 that the species was moved to *Licaria* by Dutch botanist Andre Joseph Guillaume Henri Kostermans (1907–1994), who lived in Asia. The genus contains 40 tropical American species, some producing oils and local medicines (Mabberley 1997).

Cubans have used a bark decoction for stomach ailments, and root bark and trunk extracts as stimulants and astringents (Roig 1945). A decoction of the bark has been applied to skin problems in Hispaniola, and the oil used to treat rheumatism (Liogier 1974). An undisclosed medicinal use is known from Belize (Balick et al. 2000). The wood is yellow-green, heavy (specific gravity 0.9), and has been used in posts, construction, and for making matches (Little and Wadsworth 1964, Liogier 1974).

### ***Lilium***

(Classical name from *lilium*, a lily, Greek *lirion*, AngloSaxon *lilie*)

***Lilium catesbaei***. From Institute of Food and Agricultural Sciences.

lily (from Latin *lilium* through Old English *lilie*, in English by A.D. 971); *giglio* (Italian); *lelie* (Dutch); *lili* (Gaelic); *Lilie* (German); *lirio* (Portuguese, Spanish); *Us* (Quebec)

***Lilium catesbaei*** (named for its discoverer, Mark Catesby, 1679–1749)  
Catesby's lily (a book name)

*oksatli ahissi* (*oksatli*, swelling, *ahissi*, medicine, Koasati)

pine lily (because it grows in pinelands, locally known as pine flatwoods)

***Lilium iridollae*** (a rainbow)  
Panhandle lily

Florida has four native species of *Lilium* (Wunderlin 1998). There are no records of *Lilium* having been used by indigenous Florida people, but many of the others in North America were used. Moreover, there is a long history of people using *Lilium*.

The Latin word, from Greek *leirion*, did not appear in English until about A.D. 971. The best known and useful of European lilies was *L. candidum*, the one mentioned by Shakespeare. According to an ancient Semitic legend, the lily sprang from the tears of Eve when she was expelled from the Garden of Eden, and it was the symbol of

motherhood to Sumerians, Babylonians, Assyrians, and Egyptians. Lilies were the flowers of Hera, Greek goddess of the moon, and Roman Juno, the goddess of light (Lehner and Lehner 1960).

Fresh and dried flowers are used in medicines, the pollen is used against epilepsy, and the flowers are used to scent perfumes. Mediterranean use goes back at least 5000 years when *Lilium* was drawn on Minoan (Crete) frescos (Simpson and Conner-Ogorzaly 1995). This lily is probably the “Rose of Sharon” of the Bible, and has been in cultivation since 1500 B.C. With the spread of the Christian religion, the lily was associated with the Virgin Mary and became incorporated into many religious pictures. The species is now known as the “Annunciation lily” (based on the 25 March Catholic festival of the Virgin Mary), “Madonna lily,” or “Bourbon lily” (de Cleene and Lejeune 2002).

Based on its name, the Koasati used *Lilium* as medicine. The Cherokee, the neighbors and sometime allies of the Muskogean, used at least one species of lily. These people used *L. canadense* for food during famines, and made medicines of them to treat diarrhea and rheumatism (Hamel and Chiltoskey 1975). *Lilium iridollae* in the Florida Panhandle has been confused with *L. canadense*; both were probably used by the Creeks. *Lilium canadense* was also used by the Algonquin, Huron, Ojibwa, Malecite, and Micmac (Moerman 1998).

### *Limonium*

(Philip Miller used the ancient Greek name for some marsh plant, *leimon*, a meadow or bog)

*acelga silvestre* (wild *acelga*, Spanish)

*lavande de mer* (sea lavender, French); sea lavender (comparison with the European mint called lavender, *Lavendula*)

*marrisp* (*mar*, sea, *risp*, scratch, Norwegian)

*statice* (from Latin *statice* and Greek *statikos*, to stand still, alluding to a use to stop bleeding, Italian)

*Widerstoss* (countershock, German)

***Limonium carolinianum*** (from Carolina)

canker root (used to treat sores)

ink root (presumably used to make ink)

marsh mullein (comparison with European mullein, *Verbascum*, Scrophulariaceae)

marsh rosemary (comparison with European rosemary, *Rosmarinus*)

sea lavender

Philip Miller named *Limonium* in 1754. In 1778, Thomas Walter described plants from the Carolinas he called *Statice caroliniana*. N.L. Britton realized that these New World seaside herbs should be moved, and transferred the species to *Limonium* in 1894. Now the genus *Limonium* contains about 350 species in the Northern Hemisphere (Mabberley 1997).

Roots are gathered in winter, boiled, and the liquid drunk as a remedy for colds, fever, and especially diarrhea. Raw roots are also chewed to stop diarrhea (Morton 1974). The Micmac of Nova Scotia and vicinity used a decoction of roots to fight hemorrhage caused by consumption (Moerman 1998).

### *Lineiera*

(Named by Carl Peter Thunberg for Johann Linder, 1676–1723, a Swedish botanist)

***Lindera benzoin*** (old name for some member of the Lauraceae, from Arabic *lo-benjuy* or *luban jawi*, frankincense of Java; taken into Spanish as *benjui*, *benjuy* by 1516, Portuguese as *beijoim* by 1498, and Venetian Italian as *benzol* by 1461; originally applied to the resin from *Styrax benzoin*)

*ascopo* (although Harriot [1590] 1972 does not provide enough information to be sure *ascopo* is

### ***Underna benzoin*.** From Britton and Brown 1896.

this species, his description makes it sound like that: “*Ascopo* a kinde of tree very like unto Lawrell, the barke is hoat in tast and spicie”; Geary 1955 thought it might be *Magnolia virginiana*; Carolina Algonquians)

benjamin-bush (benjamin, a corruption of *benzoin*); *benjoin* (derived from Arabic, French)

fever-bush (in use by 1760s); *Fieberstrauch* (fever bush, German)

*kaachk'aachkeek* (*kaachk'aachk*, dry, *EEK*, that which is; in other words, brittle, Delaware)

*kvpvpaskv* [*kvpvpáskv*] (spice, Muskogee)

*noh?da-tli* [*na'tu'li*] (Cherokee)

pond-spice; [common, northern] spice-bush [spicebush, spice-wood] (applied to *Lindera* in New England before 1740 according to Kalm; OED says applied in English in 1845 because of the aromatic leaves; Oklahoma Yuchi still call it “spice-wood”); wild allspice

*shábak* [*tchápaak*] (*tchap*, medicine, *aak*, shrub, Delaware)  
snap-bush

Early authors Leonard Plukenet in his *Almagestum botanicum* of 1696 and Jan Commelin in his *Hortus medici* of 1697 both noted that spice-bush smelled like the benzoin of Asia. So, Linnaeus ([1753] 1957) used “benzoin” as the species name. It is not known where Commelin obtained the specimens he cultivated. Regardless, indigenous American people had used the plants for decades.

Both the Cherokee and Ojibwa used the leaves or fruits for flavoring strong-tasting meats (Yanovsky 1936, King 1984). Opossums (*Didelphis virginiana*) and ground hogs (*Marmota monax*) were gamey meats that the Cherokees (Hamel and Chiltoskey 1975) noted were improved with this spice. That application is surely responsible for the common name “spicebush.” Physician W.P.C.Barton wrote that, during the Revolutionary War, the fruits were considered a substitute for allspice (*Pimenta dioica*, Myrtaceae) (Hedrick 1919). Ohio pioneers used young twigs and leaves as a substitute for tea and spice (Hedrick 1919).

These shrubs also had medical uses as noted by Commelin and Linnaeus. The Cherokee, Ojibwa, and Mohegan used leaves to make tea that was sometimes a simple beverage, but more often medicine. The Cherokee took the drink for blood and female problems, colds, croup, measles, and tuberculosis (Hamel and Chiltoskey 1975). The Iroquois also drank an infusion to relieve colds, fever, and measles, and the Mohegan took it to expel worms (Moerman 1998). We know only that the Ojibwa used it medicinally (Moerman 1998). The Rappahannock used an infusion for menstrual problems (Vogel 1970). In addition, the Cherokee used *Lindera* as a diaphoretic, and the Creeks used it as an emetic and in steam baths for aches (Swanton 1928a, Taylor 1940, Hamel and Chiltoskey 1975).

Settlers learned to use the bark as a febrifuge, a carminative to relieve flatulence and colic, and to treat rheumatism (Vines 1977, Foster and Duke 1990, Mabberley 1997). More recently, the plants have been recommended as an abortifacient, analgesic, candidacide, carminative, depurative, diaphoretic, emetic, emmenagogue, panacea, stimulant, tonic, and vermifuge (Duke et al. 2002). Most of those applications reflect uses by indigenous tribes.

Plants are known to contain laurotetanine, a potentially cytotoxic alkaloid. Moreover, extracts from the stem bark inhibited *Candida albicans* better than any of the other 53 plants tested (Duke et al. 2002). Yuchi still use it in a purification bath in March before entering the football game grounds (Jackson 2003).

### *Liquidambar*

(A hybrid name fluid, and composed of Latin *liquidus*, and Arabic *ambar*, amber, an allusion to the fragrant terebinthine juice or gum that the tree exudes)

*Liquidambar styraciflua* (an old generic name, from Latin *styrax*, gum, and *fluxus*, flowing)  
*Ambrabaum* (amber tree, German)

American storax; *estoraque* (from *styrax*, the plants giving aromatic resins in Asia; Oaxaca, Chiapas, Guatemala)

*a'yuxudi'* (Biloxi; plus, *ayuxu' anaki'*, the fruit; *ayuxu sintonni'*, the resin)

***Liquidambar styraciflua*.** a. Branch with fruit, b. Seeds. Drawn by Vivian Frazier. From Correll and Correll 1972.

*balsamo copalme* (copalme balsam; *copalme* based on *copalli*, resin, Náhuatl, Veracruz); *copalillo* (little copal, San Luis Potosi)

bilsted (presumably English; listed by Asa Gray 1875, USA)

*buluchka'an* (Mexico)

[alligator, American sweet, California red, red, star-leaf, white] gum [-wood]

*hacaló:pî* (Creek; compare with *helocoppi* by Simmons [1822] 1973, and *helocoppe* by Williams [1837] 1962)

*helúkfyémécv* (*helok*, black gum, Muskogee); *helokvpe* [*helúk wvpe*] (*helok*, black gum, *vpe*, tree, Muskogee); *helúkvw* [*helokvw*, *helukwa*] (Creek, Muskogee; compare with *Nyssa* and *Eugenia*); *hika* (Choctaw; the resin is called *hika nia* [*hekania*])

*ien-gua-o* (Oaxaca)

*ikob* [*icob*] (Huastec, San Luis Potosí); *itsché* (*its*, resin, *ché*, tree, Maya, Mexico); *ocop* [*occob*, *ocóm*] (Quecchí, Guatemala)

*ingamo* (maybe cognate with *ikob*, Oaxaca)

*ko'ma* [*ko'ma'lisho*] (Totonac, Puebla)

*kum hasana're* (gum resin, Catawba)

*lesquin* (Central America)

liquid amber [liquid-amber] (in use in English by 1589; mentioned by Bartram [1791] 1958); *liquidámbar* [*diquidambo*, *qiramba*] (Oaxaca, Guatemala, Honduras, Nicaragua); *kirambo* (perhaps a corruption of *liquidambar*, Huastec, San Luis Potosí); oyl of amber (from 1657, England)

*ma'lah*<sup>2</sup> [*ma-la*] (Chinantec, Oaxaca)

*maripenda* (Tarascan, Michoacan)

*nabá* (Choi, Chiapas)

*nijte-pijto* [*nite-biito*, *nite biito*] (*pi*, *biito*, fruit, Zapotec, Oaxaca)

*ocótzotl* [*ocóxotl*, *ocozotl*, *ocozo*, *ocozote*, *ococote*] (*ocotl*, pine, *tzotl*, resin, Nahuatl, Veracruz, Oaxaca); *ocotzocuahuítl* (tree that gives pine resin, *ocotl*, pine, *tzotl*, resin, *cuahuítl*, tree, Náhuatl)

opossum-tree (“opossum” from *âpâsûm*, white beast, Virginia Algonquian)

*pekiw* (Strachey wrote this *pkekewh* and *pickuts*, compared it with “balsam,” and said it came from a tree called “the Virginia maple.” Those two clues suggest placement here. Siebert 1975 simply put the word under “gum,” the meaning in all the related Algonquian tongues. Cognates include Cree *pikiw*, Fox *pekiwa*, Menomini *pekew*, Ojibwa *pikiw*, and Penobscot *peko*.)

*somerio* (San Luis Potosí)

*suchete* (Hidalgo); *toshcui* (Zoque, Chiapas); *tzoté* (*tzotl*, resin, Nahuatl, Guatemala; also Tzotzil, Chiapas)

*sul'to'nko* (Totonac, Puebla)

sweet gum [sweetgum] (dating back to at least the 1580s)

*tih'tâmá'za* (Paya, Honduras)

*trementina de pino* (pine terebinth or resin, Mexico, Central America)

*tsila'lu'* (Cherokee; a former settlement on a small branch of Brasstown creek of the Hiwassee River, just within the line of Towns County, Georgia, was called *Tsila'lu'hi*, “sweet-gum place”); apparently cognate with *kafolá* [*kaholá*] (Koasati)

*umwé* (Jicaque, Honduras)

*xochiocotzotl* [*xochiocotzol*] (*xochitl*, flower, *ocotl*, pine, *tzotl*, resin, name for the gum, Náhuatl); *xochiocotzo quahuítl* [*xochiocotzocuahuítl*, *xochicatscudhuítl*, *xochiquahuítl*] (*xochitl*, flower, *ocotl*, pine, *tzotl*, resin, *cuahuítl*, tree, Náhuatl); *xochiatl quirámbaro* (*xochitl*, flower; the second word may be a corruption of *liquidámbar*, San Luis Potosí, Veracruz)

*yaga bizigui* [*bicigui*] (*yaga*, tree, *pi*, fruit, Zapotec, Oaxaca); *yaga huille* (*yaga*, tree, Zapotec, Oaxaca); *yaga pito* [*yaga bito*, *yaga pito*, *yaga vio*, *yaga vido*, *pijto*, *vito*] (*yaga*, tree, *pi*, fruit, Zapotec, Oaxaca)

*yassaako* [*yassdako*] (related to *yaska*, to chew, Alabama)

“Storax” came into English by A.D. 1382 from “*torax*” and in 1388 as “*storax*,” a fragrant balsam from the bark of an Asian tree now known to be *Liquidambar orientalis*. Sometimes the resin is called the “Levant storax” because it came into Europe through the Holy Land. The gum is also the “balm of Gilead” of the Bible (Mabberley 1997).

There are two versions of the origin of the word “storax,” although the argument that it is from Hebrew *tzori* is surely correct. Zohary (1982) noted that the name *tzori* appears six times in the Bible, three of those associated with Gilead. Its Hebrew synonym *kataf* or *nataf* also occurs. He agreed with an earlier suggestion that Greek *styrax* was derived from Hebrew *tzori*.

The other version is that “storax” came from the Greek and Latin *styrax*, a word now used for plants in the Styracaceae. Quattrocchi (1999) said that the Greek *styrax* or *styrakos* is a corruption of Arabic or Semitic *assthirak* for *Styrax officinalis*. Zohary (1982) did not accept that interpretation because the Hebrew name for *Styrax* in the Holy Land is *livneh*. Moreover, that name and the Arabic *libna* and *abhar* (white, bright) are cognates. More convincing, *S. officinalis* yields no gum. It is *S. benzoin* from Asia that produces the aromatic gum, and it was introduced later. Europeans may not have known storax plants by the time the Americas were discovered, but they certainly recognized that gum from the Holy Land.

One of the first references to sweet gum in the United States was in the 1580s by Thomas Harriot ([1590] 1972) although it is not clear that he was talking about *Liquidambar* alone. He wrote: “Sweete Gummes of diuers kindes and many other Apothecary drugges of which wee will make speciall mention, when wee shall receiue it from such men of skill in that kynd.” Only shortly afterward, in 1589, the name *liquidambar* was used by John Florio in his book *A worlde ofwordes*, which was a dictionary of Italian and English (OED 1971). In 1616, another author wrote, “*Liquid Amber*. A sweete Rosin brought from the West Indies, comfortable to the braine.”

By the time Culpeper (1653) wrote his *Complete Herbal*, he had completely confused the American with the Old World storax. He called storax *L. styraciflua*, but gave its range as the southern part of Europe, Greece, Turkey, and Syria. Regardless, both species yield gums so similar they may not be distinguished without chemical analysis, and maybe not then (Duke et al. 2002).

The fragrant gum from *L. styraciflua*, also called copalm balm, American copalm, and storax, is obtained from the inner bark after wounding or gashing a tree. This gum has a long history of use by the Aztecs and people farther north (Standley 1920–1926, Martinez 1969). Romans ([1775] 1961) tells us that the Choctaw mixed dried, crumbled leaves of *Liquidambar* with their tobacco for smoking.

Three Muskogean tribes are known to have used *Liquidambar* gum as medicines, as did their neighbors the Natchez and Cherokee. The Choctaw made a poultice to help cure cuts and bruises (Bushnell 1909). The Houma similarly put a dressing on skin problems (Speck 1941). The Koasati took a decoction of the bark for “Night Sickness” (Taylor 1940). Du Pratz in 1758 recorded that the Natchez used the sweet gum, probably like their neighbors the Houma (Swanton 1946). The Cherokee used the rosin or inner bark to make in a salve for wounds, sores, ulcers, and itch (Hamel and Chiltoskey 1975). They also used the salve to treat diarrhea, flux, and dysentery. They made an infusion to treat certain types of female problems and considered it sedative. The Rappahannock made a bark infusion to stop dysentery (Moerman 1998).

The Cherokee also chewed the hardened gum and made a beverage with the bark mixed with *Evonymus* and *Vitis* (Hamel and Chiltoskey 1975). Settlers adapted several of these indigenous applications using it as chewing gum, antiseptic, and to treat skin diseases and dysentery (Standley 1920–1926). Sweetgum was popular with Confederate doctors (Mabberley 1997, Diggs et al. 1999). Porcher (1863) wrote: “The inner bark contains an astringent, gummy substance. If it is boiled in milk, or a tea made with water, its astringency is so great that it will easily check diarrhoea, and associated with the use of other remedies, dysentery also. The leaf of the gum when green I have also ascertained to be powerfully astringent, and to contain as large a proportion of tannin as that of any

other tree. I believe that the Gum leaf and the leaf of the Myrtle and Blackberry can be used wherever an astringent is required; cold water takes it up. They can, I think, be also used for tanning leather, when green, in place of oak bark.”

Apparently, the American species contains many of the same compounds as *L. occidentalis*. That species has cinnamic acid, cinnamein, styrol, vanillin, and resins (Hocking 1997). The oleoresins are used as the chewing gum. *Liquidambar formosana* has similar chemicals (Hsu 1986).

The first record of this species in Mexico was made by Bernal Díaz del Castillo between 1517 and 1521 (Diaz 1956). In describing the meals of the Mexican emperor Moctezuma, he says: “After he had dined, they presented to him three little canes highly ornamented, containing liquid amber, mixed with an herb they call tobacco, and when he had sufficiently viewed and heard the singers, dancers, and buffoons, he took a little of the smoke of one of these canes.” The balsam and gum were used to flavor tobacco and as incense in houses and temples. Few people realize it today, but smokers burn a similar mixture; modern tobaccos have *Liquidambar* in them for added flavor (Meyer 1997).

Wood from *L. styraciflua* is known as “stainwalnut” in the trade. This wood has been used for flooring, furniture, veneers, woodenware, construction, boxes, cross ties, barrels, sewing machines, cabinets, molding, vehicle parts, conveyors, musical instruments, and tobacco boxes (Vines 1977). Foster and Duke (1990) also noted that sweetgum is an ingredient in “compound tincture of benzoin” still available in pharmacies.

### *Liriodendron*

(From Greek *lirio*, lily or tulip, and *dendron*, tree, alluding to similarity with tulips, *Tulipa*)

***Liriodendron tulipifera*.** From Sargent 1905.

***Liriodendron tulipifera*** (bearing tulips; an old generic name for the plants)

basswood (comparing the bark with that of *Tilia*; see quote by Kalm below)

canary yellow-wood

canoe-tree (used by Swedes in Pennsylvania when Peter Kalm visited in 1748)

cucumber tree (some thought the “fruits” resembled cucumbers, *Cucumis sativus*)

*es-pe-ton-ga* (Osage)

old wife’s shirt tree; old woman’s smock (a name used by the English in Pennsylvania by 1748 because of the similarity of the leaf shape to a shirt)

[blue, hickory, soft, white, yellow] poplar (“poplar” is a term applied to a large variety of trees; see *Populus*; in use for these plants by 1705 in Virginia and by Englishmen in Pennsylvania by 1748; Kalm explained that people thought there were two “kinds” of trees; some yielding white wood, and others yellow)

popple (variant of poplar); sap poplar (maybe referring to extracting sap from the trees to make sugar); tulip-poplar [tulip poplar, tulip bearing poplar] (the word “tulip,” first recorded in English about 1554; is derived from *tuliband*, a Turkish pronunciation of the Persian *dulband*, turban; the name was applied because of the resemblance of the expanded flower to the headgear); tulip tree [tuliptree, tulip wood] (although the first appearance in print in English was in 1705, the Latin version had been in use since at least the 1690s)

saddle-leaf [saddleleaf, saddletree] (alluding to the shape of the leaves)

whitewood (Plukenet may have used the word first in 1696 when referring to a tree from the West Indies, but he mentioned the tulip tree in the same sentence)

*yap sake*? (tree red, Catawba)

Linnaeus gave us *Liriodendron tulipifera*. In naming it, he used a collection sent to Europe by John Clayton in the 1730s, but that was not the only material he had studied. The oldest record of this species in Europe was published by Leonard Plukenet in 1696. He called the plants *Tulipifera caroliniana*, *foliis productionibus magis angulosis* (Tulip-bearer from Carolina, producing large, angular leaves). However, Plukenet also had the trees in his book listed under the name *Tupilifera virginiana*, *tripartito aceris folio* (Tulip-bearer from Virginia, with threeparted leaves resembling maples). He thought that there were actually two different kinds of plants and he gave them distinct names. Linnaeus had also studied living plants at the *Hortus Cliffortianus* and *Hortus Upsaliensis*.

Moreover, by the time he published the name of these plants in 1753, Linnaeus had discussed them with his former student Peter Kalm ([1753–1761] 1972). Kalm knew firsthand about the size of old plants in New England and surely conveyed that to Linnaeus.

Kalm ([1753–1761] 1972) wrote, “canoes are boats made from one piece of wood...for that purpose a very thick trunk is hollowed out.” He listed as preferred woods both cedars (*Chamaecyparis*, *Juniperus*), chestnut (*Castanea*), white oak (*Quercus*), and tulip tree. His comment that the “Indians” made their canoes from them is surely one of the oldest on record. Moreover, he was talking about tribes that were not mentioned by Moerman (1998), probably the Delaware. Yet, it cannot be restricted to them because the trees were probably used by all in the region. People as far south as the Cherokees are

recorded as making canoes 30 to 40 feet long from the trees (Hamel and Chiltoskey 1975).

These trees were so useful to the people of the region that Kalm ([1753–1761] 1972) spent considerable space commenting on them. He wrote: “Its wood is here made use of for canoes, boards, planks, bowls, dishes, spoons, door posts, and all sorts of joiner’s work. I have seen a barn of considerable size, whose walls and roof were made of a single tree of this kind, split into boards. Some joiners reckoned this better than oak, because the latter frequently is warped, which the other never does, but works very easy; others again valued it very little. It is certain, that it contracts so much in hot weather, as to occasion great cracks in the boards, and in wet weather it swells so as to be near bursting, and the people hardly know of a wood in these parts which varies so much.... The bark (like *Russia* glass) is divisible into very thin leaves, which are very tough like bast.... The leaves, when crushed and applied to the forehead, are said to be a remedy against the head-ach. When horses are plagued with worms, the bark is pounded, and given to them quite dry. Many people believe its roots to be as efficacious against the fever as the Jesuit’s bark.”

George H. Loskiel in 1794 wrote that the fruit and bark were a powerful Indian remedy against agues (Vogel 1970). Unfortunately, no tribes are mentioned. The earliest direct record of indigenous people using *Liriodendron* was published by Hunter ([1823] 1973). He wrote that the Osage at least, and probably the Kansas, used the root bark to treat malaria (intermittent fevers). Fruits (“seed balls”) were given to children to destroy worms.

Later studies found that the Cherokee gave an infusion of the bark to expel pinworms, to treat boils, cholera, coughs, dysentery, dyspepsia, fever, hysteria, rheumatism, snakebite, and wounds (Hamel and Chiltoskey 1975). The Rappahannock made a poultice for headache and chewed the bark as stimulant (sex vigorant) (Moerman 1998). Vogel (1970) noted that the modern Catawba were using the roots as a vermifuge.

Physicians and other scholars who praised the value of remedies from *Liriodendron* included Johann D. Schopf after visiting North America in 1783–1784, Benjamin Barton in his 1810 and 1812 books, Jacob Bigelow in *American Medicinal Botany*, published between 1817 and 1820, and Rafinesque (1830). They considered the plants effective against rheumatism and arthritis, fevers, snakebites, and as a diaphoretic (Vogel 1970). Porcher (1863) wrote, “Tulip Bearing Poplar (*Liriodendron*) and the Willow bark supply a remedy for the fevers met with in camp. Cold infusion given.” Later he recommended “employing the *Liriodendron tulipifera* as a substitute for quinine during the stage of intermission of all mild cases of intermittent fever.” Hocking (1997) summed it up with the statement that the bark was chewed as a tea substitute and that “poplar bark” was used to treat hysteria.

*Liriodendron* bark was official in the U.S. Pharmacopoeia from 1820 to 1882, as a bitter tonic, antiperiodic, and diuretic (Vogel 1970). It is now known that the plants contain liriodendrin (diglucoside of liriorelinol), a digitaloid substance, and tannin (Hocking 1997).

***Lithospermum***

(From Greek *lithos*, stone, and *sperma*, seed, referring to the hard nutlets)

***Lithospermum carolinense*.** From Britton and Brown 1898.

*erba-perla* (pearl herb, Italian); *herbe aux perle* (pearl herb, French by 1550); pearl plant (so named because of the hard white pearl-like seeds, Britten and Holland [1886] 1965); *peerlencruyt* (pearl herb, Dutch)

*granos de amor* (grains of love, Spanish by 1557)

*grémil* (from Old French *gromil*, dating from the 1200s; etymology uncertain, although at one time thought to be from Latin *granum milii*, millet grains, Quebec); gromwell [graymile, grummell] (in use by ca. 1310, derived from Old French *gromil*)

*lithospermo* (stone seed, Italian by 1551); *steinfrø* (stone seed, Norwegian); *Steinsame* (stone seed, German)

*migliarino* (resembling *miglio*, millet, Italian)

*mijo de sol* (sun millet; *mijo* from Latin *milium*, Spanish by 1557)

painting root ("The girls in the North of Europe paint their faces with the juice of the root upon days of festivity"; Britten and Holland [1886] 1965)

puccoon (from the Powhatan word, Virginia; see *pakkan* under *L. carolinense*)

***Lithospermum carolinense*** (of Carolina)

hoary [yellow] puccoon

*itani,slá:na* (*itani* cane, *lá:na*, yellow, Koasati)

*odji'biknamuûn'* (*biknam* may be cognate with *pakkan*, Ojibwa)

*pakkan* (Strachey wrote in [1612] 1953 the Powhatan as *poughcone*, "red paint or dye," *pokcoons*, "a red dye," and *pocones*, "small root that grows in the mountains, which being dried and beat in powder turns red"; Siebert 1975 found cognates in *Penobscot pákahkan*, Mahican *pkáhhkan*, and Nanticoke *pakahk*, all meaning "blood")

***Lithospermum incisum*** (sharply cleft leaves)  
 narrow-leaf gromwell [narrowleaf gromwell]

Common names offer a glimpse into the thoughts and views of other people and cultures. However, those names must be used with caution. I learned *Lithospermum* as “yellow puccoon” when I was young. Another plant used in herbal medicines I learned as “goldseal” (*Hydrastis canadensis*). My mother’s family talked about and gathered “yellow puccoon” when she was young, and I could never find that much of it growing around the area where they lived. There was plenty of goldseal, but *Lithospermum* was indeed rare. Sometimes I wondered if they had overcollected it.

It was only much later that I discovered that both *Hydrastis* and *Lithospermum* are known as “yellow puccoon.” These plants have entirely different chemicals and properties and a mistake in using one for the other—for anything except coloring—might prove fatal.

Linnaeus ([1753] 1957) created the genus *Lithospermum* with six species, only one of them from the Americas. He did not invent the name but adapted it from Caspar Bauhin’s *Pinax* of 1623 and earlier authors. The best known of the species was what he called *L. officinale*, which had a long history of medical use. Leonard Fuchs (1542) called this *Lithospermon* (Greek), *Lithospermum* (Latin), and German *Meerhirs* (sea millet) or *Steinsamen* (stone seed) (Meyer et al. 1999). Pliny (A.D. 23–79), Dioscorides (fl. A.D. 40–80), and Paul of Aegina (A.D. 625–690) also discussed the herb.

The only species Linnaeus knew from North America in 1753 was *L. virginianum*, a species that does not reach Florida. It was not until J.F. Gmelin revised *Systema Natura* in 1791 that one of the *Lithospermum* in Florida was named. Gmelin called the herbs *Batschia caroliniensis*, and it was not until 1892 that Conway MacMillan (1876–1929) created *Lithospermum carolinense*.

The Ojibwa used the dried root of *L. carolinense* to make a red dye. In making the dye, the women mixed dried and pounded roots with water and ochre. For coloring porcupine quills, they boiled the roots in water, added the quills that had previously been soaked in hot water, and let the mixture stand. If the color was not what they wanted, they repeated the process (Densmore 1928). The same tribe used the roots to make a red face paint (Moerman 1998).

Although neither Vogel (1970) nor Moerman (1998) gives the same information, Hocking (1997) said that the Ojibwa also used this species as a vermifuge. Otherwise, the only record found of medical use was among the Lakota who treated chest wounds with powdered roots (Moerman 1998).

The other species, *L. incisum*, appears to have no records of use in the east, but many in the western parts of North America. Records exist for use by the Blackfoot, Comanche, Hopi, Navajo, Okanagon, Shoshoni, Sioux, Thompson, and Zuni (King 1984, Moerman 1998). In Veracruz, the Zoque-Popoluca use it to treat snakebite (Vasquez and Jacome 1997).

The Shoshoni used the roots to make a blue dye. The Thompson people dipped the roots in hot grease and used them as red paint on their bodies and on tanned leather.

The Blackfoot used *L. incisum* roots to make a tea. They and the Shoshoni, Okanagon, and Thompson ate them boiled or roasted. The Blackfoot also burned the dried tops as incense. The Cheyenne put the dried plants on paralyzed body parts. They used an

infusion or chewed the plant and put it on the patient to relieve irrational behavior and as a stimulant. The Hopi used *L. incisum* to stop hemorrhages and to build up the blood. The Navajo made a cold remedy by chewing the plant, took it as an oral contraceptive, to treat coughs, to treat sores of the navel, and as an eyewash. They considered it a panacea. The Sioux made a medicine of it to stop bleeding lungs. The Zuni considered it a remedy for swelling, skin abrasions, infections, stomachache, kidney problems, and sore throat.

Moerman (1998) found several other species in use including *L. canescens*, *L. multiflorum*, *L. ruderalis*, and an unidentified species among the Pima and Keres. In addition, some of the names of other plants in the eastern states are instructive. Both *L. croceum* and *L. canescens* are “puccoon.” *Lithospermum canescens*, one of the most famous eastern species, is sometimes called “Indian-paint,” and the Omaha-Ponca dubbed it *bazu-hi* (*hi*, plant) (Gilmore 1919, Fernald 1950). Presumably, most of the species were used by various tribes to make dyes of one kind or another.

### *Lobelia*

(Dedicated to Matthias de l’Obel, 1538–1616, a Flemish herbalist and physician to William Prince of Orange, who attended Lord Edward Zouche in his embassy to the court of Denmark and was physician to King James I of England)

***Lobelia cardinalis*.** From Institute of Food and Agricultural Sciences.

***Lobelia cardinalis*** (cardinal, from the color and shape of the corolla, like a miter, a pre-Linnaean generic name for *Lobelia*)

cardinal-flower (from French *cardinale rouge*, cardinal red, alluding to the red color of the flowers and cardinal's robes, from 1698 when James Petiver published the name)

*héce-ôme* (*héce*, tobacco, *hôme*, bitter, Muskogee)

*hierba de piojo* (louse herb, Veracruz)

hog physic (fide Meyer and Meyer 1986)

*inote'wi* (said to mean "Indian tobacco," but maybe not literally, Meskwaki and Potawatomi)

*lobélie éscarlate* (scarlet lobelia, French); *Lobelia scharlachrote* (scarlet red lobelia, German)

red betty; red cardinal; red lobelia

*totkv heleswv* (*totkv*, fire, *heleswv*, medicine, archaic Muskogee)

*totkv mocasv* (*totkv*, fire, *mocasv*, new, Muskogee)

*tsaliyu'sti* (*tsálu*, tobacco, *iyu'sli*, like, resembling, Cherokee)

The name "lobelia" came into English in 1738 when Philip Miller published "Shrubby lobelia with a purslane leaf" in his *Gardeners Dictionary*. Miller simply translated the Latin phrase name *Lobelia frutescens, portulacae folio* used by Charles Plumier in 1703. Europeans knew *Lobelia* when they arrived in the New World. There are three species now recognized in *Flora Europaea* (2003), but only *L. wrens* is widespread in the Mediterranean.

Not much notice was taken of *Lobelia* until the 1700s when Europeans in America discovered that the indigenous people considered some of the species cures for venereal diseases. Supposedly, the first account of use for this purpose was among the Iroquois, and Sir William Johnson, an official agent of the British government among the northern tribes, is said to have purchased the remedy from them in the early 1700s (Millspaugh 1892). Given the comment that the Iroquois "held this plant a secret in the cure of syphilis" and got Johnson to pay them for it, one has to wonder who was tricking whom.

Cadwallader Golden (1688–1776), a physician, botanist, and statesman in New York, was another person who worked among the Iroquois. He promoted among settlers use of the species Linnaeus called *L. syphilitica* in 1753. In 1758, Golden claimed that lobelia had cured soldiers of syphilis in less than a week (Vogel 1970). Not long after its introduction into Europe, people realized that *L. syphilitica* did not work and abandoned it (Millspaugh 1892).

*Lobelia cardinalis* is considered the sister species to *L. syphilitica*, and hybridizes with it (Diggs et al. 1999). Both of these were thought by indigenous people to be weaker than *L. inflata*, but employed for similar purposes. *Lobelia inflata* was so popular among New England people that it received the English common name "Indian tobacco." Cherokee applied their name, *tsaliyusti*, indiscriminately to more than one *Lobelia* and even to *Verbascum*, an introduced European weed (Mooney 1885–86). That name is appropriate for all, because *Lobelia* contains lobeline, which acts much like nicotine in poisoning the central nervous system (Diggs et al. 1999).

The first record of *Lobelia* probably was made by Francisco Hernandez (1651) who called them *Rapuntium maximum, coccineo spicato flore* (the largest little turnip with

scarlet flowers in a spike). Whether he was describing *L. cardinalis* or *L. laxiflora* is problematical. The Aztecs were well acquainted with the latter species, which they called *chiplanxochitl* (*chilpan*, medicinal plant, *xochitl*, flower, Nahuatl). They had long used that herb as an emetic, expectorant, and antispasmodic (Martinez 1969). Alternatively, it could just as easily have been *L. cardinalis*, as it goes south to Panama. People in Veracruz still use *L. cardinalis* to rid themselves of lice (Vásquez and Jacome 1997).

The Cherokee used a poultice of crushed *L. cardinalis* leaves to relieve headache and rheumatism. They also used an infusion to expel intestinal worms, relieve colds and croup, and cure sores, fever, stomach problems, nosebleed, and syphilis (Hamel and Chiltoskey 1975). The Delaware used a root infusion to treat typhoid (Moerman 1998). The Iroquois added *Lobelia* to many of their medicines to strengthen them. A poultice or infusion treated pain, sores, fevers, stomach problems, cramps, sore breasts, and menstruation problems (Moerman 1998).

The Iroquois, Meskwaki, and Pawnee employed cardinal-flower as a medicine to end quarrels between husbands and wives (Gilmore 1919, Moerman 1998). The Meskwaki also considered it a ceremonial “tobacco” that was not smoked but offered to the deities to ward off storms and spirits of the dead (Moerman 1998). Similarly, the Iroquois considered it a mystical plant that could ward off spells, and generally divert bad things (Moerman 1998).

Gilmore (1919) was convinced by the disjunct isolated populations of *L. cardinalis* that the Missouri River *wazathe* (healers, Omaha) had introduced them from farther east. He makes a convincing argument for the movement by indigenous healers of cardinalflower, ginseng (*Panax quinquefolia*), sweet flag (*Acorns calamus*), columbine (*Aquilegia canadensis*), and some others.

The entire *Lobelia* plant is poisonous to humans and livestock, and can cause death. One view of toxicity was given in 1855, when Thomas C. Haliburton wrote in his *Nature and Human Nature*, “He foamed at the mouth like a horse that has eaten lobelia in his hay” (Haliburton in OED 1971). Porcher (1863) wrote, “This plant is used by the Indians as an anthelmintic—some say quite as efficient as the pinkroot [*Spigelia marilandica*; see *Spigelia*]. Mérat says it is employed as a poison by the negroes at the Cape of Good Hope.” Unless *L. cardinalis* had been introduced to southern Africa, it could not have been used as Porcher says. The species is native to the Americas.

*Lobelia* has a variety of pyridine alkaloids, with more than 14 having been isolated from *L. inflata* (Turner and Szczawinski 1991). The most abundant alkaloids are lobelamine and lobeline. Overdoses will cause vomiting, paralysis, depressed body temperature, coma, and death (Lewis and Elvin-Lewis 1977). Plants also contain the pungent volatile oil lobelanin.

Meyer and Meyer (1986) say the flowers were used by rustics as a red dye. Unfortunately, they did not say who the “rustics” were, or how to make the dye.

*Lonicera*

(Named to commemorate German herbalist Adam Lonitzer, 1528–1586; his name was rendered *Lonicerus* in Latin)

***Lonicera sempervirens*.** From Britton and Brown 1898.

*caprifoglio* (goat leaf, Italian); *caprifolium* (goat leaf, Latin); *chèvrefeuille* (goat leaf, Quebec); *Geissblatt* (goat leaf, German)

*fèithlean* (*feith*, sinew, *lean*, follow, Gaelic, for *L. peridymenum*)

honeysuckle (the name alludes to being able to suck nectar from the flowers; from Middle English *hunisucle*, a name in use by ca. A.D. 1265, when applied to clover flowers; later applied to *Lonicera* by 1548)

*ladh-shlat* (twig that surrounds, Gaelic)

*leddved* (joint wood, Norwegian)

*lus na meala* (honey plant, Gaelic)

*madre selva* [*madreselva*] (mother of the forest, in use by 1557, Spanish); *madresilva* (mother of the forest, Portuguese); *matersylva* (mother of the forest, Latin)

*mammekenscruyt* (mother's herb, in use by 1549, Dutch)

*okshulba* (Choctaw)

*owehkim ako'pukwa* (Plains Cree)

*pakaalakomahli* (*paxkaali*, flower, *akomahli*, cantelope [*Cucumis melo*], a plant that was brought to the New World; surely a transfer from a native species, Alabama)

*panhin a'xiyehi' hupi'hi* (vine with fragrant blossoms, Biloxi; this may be a name for introduced *L. japonica*)

*papahitikwa* (Plains Cree)

*periclymenon* (literally “famous twiner,” Greek)

*vincibosco* (conquers forests, in use by 1551, Italian); *vincibosse* (conquers forests, in use by 1551, French)

*volucrum mains* (flying May, Latin)

***Lonicera sempervirens*** (evergreen)

*aatyammichi* (*aati*, Indian, *yammi-chi*, to get someone intoxicated, Alabama; perhaps confused with *Gelsemium sempervirens*, which see)  
 coral [crimson, scarlet, trumpet] honeysuckle (referring to the red corollas; in use by 1753)  
 woodbine (in use by 1753; used by Porcher 1863)

The shift from a plant with a leaf that smells like a she-goat or the odor from the armpit (*caprifolium*) to honeysuckle reflects a major change of view. Or perhaps it was simply a result of more people living in cities and towns where the plants are grown for the flowers and their sweet nectar. In either case, Europeans had a variety of names and opinions regarding honeysuckles when they arrived in the New World.

Leonard Fuchs discussed *Lonicera periclymenum* in 1542 and used its pharmaceutical names *Caprifolium* and *Matersylva*. These plants were famous for having been discussed by Dioscorides (fl. A.D. 40–80), Galen (A.D. ca. 129–ca. 199), and Pliny (A.D. 23–79). At the time, that species was believed to heal ulcers, impetigo, and other skin problems, shrink the spleen, help breathing difficulties, speed childbirth, and clear facial spots (Meyer et al. 1999).

Linnaeus ([1753] 1957) put 15 species in *Lonicera*, a name he created in *Hortus Cliffortianus* in 1738. Of those, 5 were from the Americas. Before him the species he named *L. sempervirens* had been discussed by Paul Hermann in 1687 and August Rivinus in 1690, so the plants had been growing in Europe for more than a half century. That they were there is no wonder because of their arresting red flowers. These twining shrubs still command the attention of hummingbirds in the Americas and the attention of people with gardens throughout the temperate parts of the world.

Vogel (1970) found no records of *L. sempervirens* being used by indigenous people. Moerman (1998) did not find any either, but he discovered that 13 other species were used—including introduced Japanese honeysuckle (*L. japonica*). In the eastern parts of North America *L. canadensis* was used by the Iroquois, Menomini, Montagnais, and Potawatomi. *Lonicera dioica* was medicine for the Algonquin, Cree, Iroquois, Meskwaki, and Ojibwa. The Iroquois made remedies from *L. oblongifolia*.

During the Civil War, Porcher (1863) wrote of *L. sempervirens*: “The plant is not much used in medicine. The syrup made of the leaves is given in asthma, and in angina tonsillaris. The leaves and bark of the *L. caprifolium* of Linn, are styptic and acrid; the flowers diuretic; the latter in decoction calm the pain of colic (*coliques ou tranchées*) following childbirth.” None of the Eclectics mentioned the genus (Culbreth 1910, Felter 1922), and Bown (1995) and Duke et al. (2002) discuss only Old World species. The Alabama name *aatyammichi* makes it seem that we have all missed something.

### *Ludwigia*

(Named for German physician Christian Gottlieb Ludwig, 1709–1773, professor of medicine at Leipzig)

***Ludwigia palustris*.** From Britton and Brown 1897.

***Ludwigia palustris*** (of marshes) *akasi* (Mikasuki; maybe from *ak*, water, and *assi*, leaf)  
seedbox

***Ludwigia virgata*** (like a twig)  
*hoktvlkolowv vhakuce* (Snow and Stans 2001 translate this as “old lady’s paint pot,” Creek; from *hoktvl*, old woman, *kolowv*, glue, *em*, her, *locowv*, clay jug, *vhake*, resembling, *uce*, little; see discussion below)  
*koldtbahcayikē [kolatbatcaitci, kolotpahche ayekche]* (*kolotpahche*, wide-open [sore], *ayekche*, medicine, Mikasuki)  
primrose willow

Decoctions of *Ludwigia virgata* root are used as a bath for “Snake Sickness” (itchy skin) (Sturtevant 1955). *Ludwigia palustris* also was part of the “Snake medicine” (Sturtevant 1955).

Although Snow and Stans (2001) list *L. virgata*, no use is given. The Creek name provides a great deal of information about their beliefs that is not obvious from the literal translation. The name *hoktvlkolowv* seems straightforward. However, it contains *Kolowa*, which was a feared demon, also called *vkolowetv*. The *vkolowetv* was a “being” that could pounce and hold with its feet and claws as does a cat. As Martin and Mauldin (2000) phrased it, the *Kolowa* was “a character much feared if it was heard halloing while a dance was being held—it could pounce like a panther.” Clearly, there is much more in the name than the simple translations suggest.

### ***Lupinus***

(*Lupinus*, of the wolf, from Latin *lupus*, wolf, because of the erroneous belief that it consumed soil fertility; akin to Akkadian *luppu*, bean, Armenian *gail*, wolf, Greek *lykos*, wolf, Hebrew *lifnāj*, interior, Sanskrit, *vrkas*, wolf)

***Lupinus perennis*.** From Britton and Brown 1897.

*altramuz* [*altramuzes*] (in use by 1557; maybe from Latin *altra*, other, and *mus*, playing card, Spanish)

fyg bene (fig bean, by Turner in 1568); *Feigbon* (fig bean, by Fuchs 1542, related to Old High German *figbōna*, Middle High German *vîge*, comparing the shape of the seeds to those of figs, German); *vijchboonen* (fig bean, Dutch by 1549)

*garbancillo* (little garbanzo, *Cicer arietinum*, New Mexico)

garden lupine (John Gerarde in 1597)

*lupin* (French by 1550); *lupin* (Norwegian); *Lupine* (German); *lupine* (in English by ca. 1420); *lupino* (Italian); *lupini bianchi* (white lupine, Italian by 1551)

*patita de la paloma* (dove's foot, New Mexico)

Quaker-bonnets

*thermis* (Greek, Fuchs 1542); *tremoço* (from Greek *thermos*, akin to Arabic *turmus*, the lupine, Portuguese)

***Lupinus perennis*** (living longer than 2 years)

[blue, sundial, wild] lupine

monkey-faces (Ohio)

old-maid's-bonnets (Long Island, Massachusetts)

sandflat-sweet-pea (Texas)

wild pea (Massachusetts, Vermont)

We humans seem to have had an uneasy relationship with wolves (*Canis lupus*) from our beginnings. When our species lived closer to nature, people respected and even revered the wolf. The fact that we domesticated wolves to create dogs gives some idea of the early relationships between the ape and canid. As cultures began living in agricultural settlements, they took less note of the natural world. In the Old World, people even began to fear the wolf although no parallel to that existed in the New World.

That same duality extended to the lupines. From an ancient misunderstanding of how plants interacted with soils, the plant's name was applied because of the belief that it robbed the soil of nutrients. Fuchs (1542) indicated instead that the plants thrived in areas where the soils were poor for growing other plants, and surely others also knew.

Some ambivalence about these plants is reflected in old Greek tales. A story told about Zeno (ca. 333–262 B.C.) of Citium of Crete, the famous founder of the Stoic school, illustrates the view. Zeno had a surly but humorous disposition; after drinking enough wine, he compared himself to the lupine—which loses its bitterness when soaked in water (Baumann 1993).

Along the same lines, lupines were part of the special food for visitors to the Oracle of the Dead on the bank of the river Acheron, Epiros. These people had to be psychologically and physically prepared to communicate with the Underworld. They were fed alkaloid-containing lupine seeds, which prepared their perceptive states to make them believe they were talking with the dead. The species was also mentioned by Galen (A.D. 129–7200) and Pliny (A.D. 23–79) as medicinal.

It is not surprising that Dioscorides, fl. A.D. 40–80, recorded two kinds of lupines, one sweet (probably alkaloid free), and the other bitter. Both of these were probably *L. albus*, sometimes known as the Egyptian lupine or white lupine. This species was food for Egyptians, Greeks, and Romans who boiled or roasted the seeds to remove alkaloids and make them edible (Mabberley 1997). Still, Athenaeus of Naucratis (A.D. 170–230), author of *Deipnosophistai* (The Learned Banquet), said the lupine was a food in times of scarcity.

However, Athenaeus, a wealthy scribe, may have exaggerated the unimportance of lupines. Pliny, for example, said that no food is more wholesome or easier to digest than the lupine, and that they produced a cheerful countenance and a fresh complexion (Coffley 1993).

Halfway around the world, another group of people domesticated a second species of lupine. The Incas of the Andes brought into cultivation *L. mutabilis*. They call them *tarwi* [harhui]; their neighbors the Aimara say *tauri*, while in English they are pearl lupines. The Incas even developed a cultivar lacking toxic quinolizidine alkaloids (Mabberley 1997). These seeds are soaked in water and then roasted, and still are sold by the bagful by vendors in many Andean towns. They certainly lived up to Pliny's prediction and improved my disposition when I ate them.

Moerman (1998) found records of 23 or more species being used in North America outside of Mexico. Sometimes people ate the foliage, and later fed it to their horses, although both were done sparingly because of the poisons they contain. The Kwakiutl sometimes ate them raw, but only before going to bed because they became dizzy. Only the Costanoan seem to have eaten the seeds in *pinole*, with all others eating vegetative parts.

There are records for use for only one of the species in Florida. *Lupinus perennis* was made into a cold infusion and drunk by the Cherokees to stop hemorrhage and nausea (Hamel and Chiltoskey 1975). The Menomini fed it to horses to make them more spirited and lively (Moerman 1998), which is reminiscent of Pliny's comments about people's attitudes improving.

## *Lycium*

(From Greek *lykion*, a name used by Dioscorides, fl. A.D. 40–80, and Pliny, A.D. 23–79, for a thorny shrub, dyer's buckthorn, perhaps a species of *Rhamnus*; said to have been used because the shrub was growing in *Lycia*, a southwest region of Asia Minor)

*agutoli* (Italian)

*Bocksodorn* (buck thorn, German); *bukketorn* (buck thorn, Norwegian); box-thorn [boxthorn] (probably derived from buck thorn; see *Pedimelum*)

*cambronera* (Spanish)

chico bush (New Mexico)

*cilindrillo* (little cylinder, Texas, Mexico)

desert-thorn; rabbit thorn (New Mexico)

Duke of Argyll's tea-plant (John Douglas Southerland Campbell, 1845–1914, was the ninth duke of Argyll, and the governor general of Canada between 1878 and 1883)

*espinheiro de casca branca* (white-barked thorn, Portuguese)

*lyciet* (from *Lycium*, French)

*spina-cristi* (Christ's thorn, Italian)

*spina-santa* (sacred thorn, Italian)

squaw-berry

tea tree (Europe)

*tomatillo* (little tomato, Texas, New Mexico, Mexico)

wolf-berry (first applied to *Symphoricarpos occidentalis* by 1834; apparently extended to *Lycium* later)

***Lycium carolinianum*** (of Carolina)

Carolina wolf-berry (Texas)

Christmas berry (Florida)

*ch'ilib tux* (*ch'ilib*, shrub, *tux*, turkey; the name is applied because the ripe red fruits resemble the red spotting on the throat of the turkey, Maya, Yucatán)

It is not safe to assume that anything a bird or other mammal can eat is safe for humans (Hardin and Arena 1974). However, I wondered for years as I sat watching the mockingbirds (*Mimus polyglottos*) guarding fruiting bushes and gobbling down their fruits, if people could eat the berries of *L. carolinianum*. I now know the berries will not poison you, but they are not likely to become tomorrow's most popular fruit either. Fernando Chiang, the specialist on the North American members of the genus, told me, "Yes, the fruits are edible though (to my taste) not very palatable."

*Lycium* (Solanaceae) is a genus with 100 species that grows in the warm temperate regions of the world. Europe has three species and Australia one (Hitchcock 1932, Mabberley 1997). The duke of Argyll's tea-plant (*L. barbarum*, including *L. chinense* and *L. halmimifolium*) is naturalized in Great Britain and north to Norway (Mossberg and Stenberg 1994, Clement and Foster 1994, Mabberley 1997), although the species is

native from southeastern Europe to China. Presumably, the shrub was imported as a substitute for Chinese tea (Standley 1920–1926). Young shoots of *L. europaeum* have been eaten as a vegetable in Spain and Italy.

Florida's single species is native from South Carolina to Florida and west to eastern Texas and Tamaulipas, Nuevo Leon, Oaxaca, San Luis Potosí, Veracruz, Yucatán, and Quintana Roo in eastern Mexico (Correll and Johnston 1970, Chiang-C. 1981). In an unusual distribution, the species reappears in Baja California, Sinaloa, Colima, Nayarit, and Michoacán (Standley 1920–1926, Wiggins 1980, Chiang-C. 1981). Other species begin in the TransPecos region of Texas and extend through other western states and south through Mexico. Cuba has three, *L. acnistoides*, *L. carolinianum*, and *L. infaustum* (as *L. tweedianum*). The latter species, *L. infaustum*, also grows from the Bahamas south to Argentina (Correll and Correll 1982, Liogier and Martorell 1982, Bernardello 1986). In Hispaniola, *L. infaustum* is called *vidrio* (glass). Only *L. acnistoides* has a common name in Cuba, and it is called *belladona de la tierra* (wild belladonna) or *pah de gallina* (chicken tree). Cubans consider their endemic *L. acnistoides* poisonous and a substitute for the real belladonna (*Atropa belladonna*). Roig (1945) wrote that the leaves are more poisonous than the roots, which are more toxic than the fruits. Chickens are poisoned by the fruits.

Most species are listed as having edible berries, and Hardin and Arena (1974) say they are edible raw, cooked, or dried. They do not distinguish between species, and presumably included *L. carolinianum*. Fernald et al. (1958) do not mention the Florida species. Moerman (1998) lists five species, all of which have edible berries. Perhaps only *L. acnistoides* is the exception to the rule.

Other species are used medicinally. The Navajo use both *L. pallidum* and *L. torreyi* for toothache and other maladies. Both the Navajo and Zuni considered their *Lycium* sacred plants (Curtin 1947). According to Mayes and Lacy (1989), the Navajo call *L. pallidum* “god’s food” (*haaschch’ée’dáá*).

### *Lycopodiella*

(Josef Ludwig Holub, 1930-, used the diminutive form of *Lycopodium*, from Greek *lykos*, wolf, *podion*, foot)

***Lycopodiella cernua*** (nodding, drooping) (= *Lycopodium cernuum*)  
*adrangaman* (Sranan, Suriname)

*bejuco de amor* (love vine, Dominican Republic)

bending club moss (Florida, English Antilles)

*cabane de la vierge* (the Virgin’s house, Dominica)

*cabello de sacerdote* (priest’s hair, Brazil)

club-moss (Florida)

*enxofre vegetal* (vegetable sulfur, Brazil); *soufre végétal* (vegetable sulfur, French Antilles)

fern (Belize)

*helecho* (fern, Peru)

*licopodio* (lycopodium, Cuba, Peru)

*lus-bhalgair* (*lus*, herb, *bhalgair*, fox, Gaelic)  
*palma de São João* (St. John's palm, Brazil)  
*samambaia* (fern, from *ham a'bae*, that which twists in a spiral, Tupi, Brazil)  
*shapumba* (Palikur, Peru)

Linnaeus knew these nonflowering plants as *Lycopodium cernuum* in 1753. Most of the world called them by that name until the 1990s. However, back in 1964, Holub created the genus *Lycopodiella*. There are about 40 species in that segregate genus, with 2 in Europe although most grow in the tropics (Wagner and Beitel 1993).

As several of the names suggest, there is widespread use of these herbs during various festivals. They are used in Christmas nativity displays (Duke and Vasquez 1994), but they are not confined to those occasions. The name *palma de São João* suggests that it was used as a substitute for palms in Christian festivities. No use by non-Christians is known.

Spores are put on cuts, used like talcum powder, as baby powder in diapers, and have been used to coat pills and lubricate condoms (Roig 1945, LeCointe 1947, Duke and Vasquez 1994). The plant has been used to treat bladder problems, diarrhea, and dysentery (Roig 1945, Duke and Vasquez 1994). Dominicans use the plant as a bitter tea to treat fever (Ayensu 1981). This is also a medicinal plant in Belize (Balick et al. 2000). Although it is not identified or named in the text, a drawing in Snow and Stans (2001 p. 68) is surely this plant.

### *Lycopus*

(Based on Greek *lykos*, wolf, *pous*, resembling, because Linnaeus saw some similarity to a wolf's foot)

***Lycopus virginicm*** (of Virginia)  
*aniwani'ski* (talkers, Cherokee)

Virginia bugleweed [bugle-wort] ("bugle," in this sense, is from Latin *bugula*; the Latin *bugillo* was applied by Marcellus Empiricus about A.D. 400 for mints now called *Ajuga reptans*; akin to French *bugle*, Italian *bugola*, and Spanish

***Lycopus virginicus*.** From Britton and Brown 1898.

*bugula*; in English by about A.D. 1265; later applied to *Lycopus* with modifiers)

Virginia water horehound (“horehound” was originally applied about A.D. 1000 to *Marrubium vulgare*. The name came from Old English *háre*, hoary, and *húne*, the name of a plant of uncertain origin, which became *hórhowne* in Middle English; water horehound was in use by 1578 for the European *Lycopus europaeus*)

Linnaeus coined the genus *Lycopus* in 1738 for European mints, and continued its use for both *L. europaeus* and *L. virginicus* in 1753. What he saw that reminded him of a wolf is not apparent now. Today, the genus contains only four species. Two are native to Europe, and the others are native to America and Australia (Mabberley 1997).

The Cherokee took an infusion of this mint at the Green Corn Ceremony, and let their infants chew the root because it gave them “eloquence of speech” (Hamel and Chiltoskey 1975). It was also used as a snakebite remedy. The Iroquois considered it a poisonous plant (Moerman 1998). The similar *L. americanus* was used by the Meskwaki for stomach cramps (Smith 1928). Other species were used by the Blackfoot, Ojibwa, Okanagon, and Thompson tribes (Moerman 1998).

### ***Lyonia***

(Named for Scottish John Lyon, 1765–1814, a gardener in Philadelphia, Pennsylvania and Tennessee)

***Lyonia fruticosa*** (shrubby)

*aha:pó:cwântí* (strong small stem tree, from *ah-*, tree, *a:p-*, stem, *-o:c-*, small, *want-i*, strong, Mikasuki)

*có:skan* (apparently comparing it to *coskv*, the post oak, *Quercus stellata*, Creek)

***Lyonia fruticosa*.** Drawn by  
P.N.Honychurch.

staggerbush (cattle browsing on the plants are poisoned and stagger)

André Michaux called these shrubs *Andromeda ferruginea* var. *fruticosa* in 1803. They went under a number of other names following that, but George Safford Torrey (1891–1977) created *Lyonia fruticosa* in 1916. *Lyonia* now comprises 35 species in Asia, North America, and Mexico (Judd 1981).

The Seminoles used the wood for making pipe bowls (Sturtevant 1955). Now people harvest the gnarled stems and put plastic branches with plastic or silk leaves on them for indoor “planters.”

### ***Lysiloma*: Wild Tamarind**

(Greek, *lysis*, opening, *loma*, margin, the fruits)

Not long after I moved to Florida, I found a single wild tamarind (Florida, Bahamas) tree growing in a coastal hammock in the town of Ocean Ridge south of Boynton (Palm Beach County). According to the books I had available, the plants (*Lysiloma latisiliquum*) were native to the Florida Keys and southern Miami-Dade County. Because I was doing a study of that hammock for another purpose, we listed the species there with a note as a curious range extension (Austin and Weise 1972). It was only later that I learned, much to my embarrassment, that the tree had been brought from the Miami area and planted by the McGinty brothers. Those wealthy brothers, avid amateur malacologists, lived only a short distance

***Lysiloma latisiliquum*.** a. Flowering branch, b. Leaf outline, c. Flower, with subtending bracts, d. Stamens, e. Pistil, f. Floral diagram, g. Fruit. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982.

north of the hammock. When they collected tree snails (*Liguus*) farther south in the state, they occasionally released some of them in the tropical forest near their house. They thought that the snails needed another food source and knew that wild tamarind would serve admirably. So, later I quietly corrected my error (Kreiger and Austin 1975).

It has always struck me as curious why this tree came to be called wild tamarind. The true tamarind (*Tamarindus indica*) is native to the Old World, and belongs to either the subfamily Caesalpinoideae or the distinct family Caesalpinaceae, depending on the specialist consulted. *Lysiloma* belongs in the subfamily Mimosoideae (or family Mimosaceae). The gibbous flowers of the Caesalpinoideae differ from the radially symmetrical blossoms of the Mimosoideae. Their flowers are not the only difference. Fruits of *Tamarindus* are indehiscent and contain abundant sweet pulp around the seeds. The genus *Tamarindus* is Latinized from Arabic *tamar-hindi* (date of India), in reference to the wide ancient use of the fruit pulp by people in India and nearby countries. Fruits in *Lysiloma* are dehiscent and do not have pulp.

Since there are other species called “wild tamarind” beginning at earlier dates, as, for example, *Pithecellobium arboreum* in the 1830s and *P. dulce* in the 1860s, the name looks suspiciously like an extension of use from those plants. Perhaps slaves traded between the notorious importation and distribution centers of Jamaica and Trinidad

brought with them a recollection of *P. arboreum* in those areas. Maybe they applied the name to the most similar trees they found elsewhere. Supporting that contention may be that both *Lysiloma* and *P. arboreum* also are called *tengue* (Taino?, Cuba).

Finally, I discovered that the external traits that I had been using were not the similarities that led to several species being called “tamarind.” The wood was the source of the names, as it is dark red, hard, heavy, and compact in all three genera. That same comparison of wood probably also led to the common name *bacona morada* (purple *bacona*, maybe Taino, Cuba). The tree called *bacona* is *Alchorea latifolia*, Euphorbiaceae. It is more certain that horseflesh (Bahamas, usually for *L. sabicu*), *sabecú* (Taino, Cuba), and *sabecú amarillo* (yellow *sabecú*, Cuba) refer to the wood. *Lysiloma* is also called *moruro de costa* (coastal *moruro*, Taino?, Cuba), and the similar name *moruro abey* (Cuba) is applied to *Peltophorum adnatum*, another legume with similar wood. The “model” for *abey* is either *Poeppegia procera* (Fabaceae) or *Ouratea littoralis* (Ochnaceae). It would not be a surprise to discover that the names *jigüe* (Taino?, Cuba), and *jigüe blanco* (white *jigüe*, Cuba) were comparisons of wood between *Lysiloma* and other species.

Three other names also seem to be indirect references to the wood. *Zapatero* (shoemaker) surely refers to using the wood as lasts or other shoe-making utensils. Perhaps *tabernan* [*tabernon*, *tavernon*] (innkeeper, Dominican Republic) and *taverneau* (variant of *tavernier*, innkeeper, Haiti) denote use of the wood in buildings. The wood is used in carpentry, for railroad ties, for making boats in the West Indies, and for bobbins, shuttles, and cabinetwork. Indeed, the wood has been exported to England for use in the textile industry (Morton 1981). Timber from the tree is considered good quality and durable in water.

The names *dormido* (sleeper, Cuba) and *soplillo* (delicate one, Cuba) have been given to *L. latisiliquum* (Barneby and Grimes 1996). Both refer to the leaves, with *dormido* a comment on the “sleeping” movements of the leaflets at night. That name is used for some other legumes with those movements. The *soplillo* must be a commentary on the fine leaflets. While those same authors attribute the common name “singing bean” to Florida, no others in the state have found that used in at least three decades.

Some of the other names are intriguingly obtuse. Why the trees are compared with candles in *candelón* (big candle, Hispaniola) or to snails with *caracoli* (snail, also for *Pithecellobium unguis-cati*, Hispaniola) and *caracolillo* (little snail, Dominican Republic) remains unclear. A romantic would suggest that the flowering trees resemble big candles. Maybe the curled fruits on the others led to the snail comparison. Or could it have been a reminder that the trees are favored hosts for tree snails (*Liguus*)? The Maya have three names for the species: they say *ts'aslam* [*tzalam*, *tzalán*, *salom*] (simple term, Yucatán, Belize), *tzukté* (*zuk*, horse's mane, Yucatán), or *xiaxek* (*ya'ax*, green, *ek*, star, a name typically given to *P. mangense*, Yucatán). Perhaps those Mayan names also allude to the wood.

There is a distressing confusion in the literature about the delimitation of *L. latisiliquum* and related species. The species was first introduced to Europeans by Charles Plumier in 1703 based on plants that he drew in Hispaniola. Then Linnaeus put the species in *Mimosa latisiliqua* in 1753 along with 38 others. Subsequently, it has been discovered that Linnaeus put multiple genera in his concept of *Mimosa*. Several of these species now have been segregated into *Acacia*, *Albizzia*, *Entada*, and *Pithecellobium*.

When George Bentham, a long-time president of the Linnean Society of London, first studied these Caribbean trees he realized that they needed a distinct generic name. He created *Lysiloma* for them in 1844, and named those in the Bahamas *L. bahamensis*. Similar trees on Cuba he named *L. sabicu*. Later he moved Linnaeus's *Mimosa latisiliqua* to *L. latisilicum*.

As recently as Liogier (1974), both *L. latisilicum* and *L. bahamensis* were considered distinct. Subsequent study of the Bahama plants showed that these two were actually the same, and they were treated as one by Correll and Correll (1982). Indeed, in their treatment, they considered *L. latisilicum* as growing only on mainland Mexico and Mesoamerica. The Corrells thought that *L. sabicu* was found only on Cuba, the Bahamas, and Hispaniola (Correll and Correll 1982). Later, Barneby and Grimes (1996) examined the problem and came to a different conclusion. This pair wrote that *L. latisilicum* is native to peninsular Florida, the Florida Keys, and the Bahamas (but unknown from Andros), extends south-east from Grand Bahama to the Caicos Islands and the northwestern coast of Haiti and Cuba, and then reappears in Tabasco, Yucatán, and Quintana Roo, and south to Belize, Honduras, and Peten, Guatemala.

Barneby and Grimes (1996) also found that *L. sabicu* is native to Cuba, the Bahamas, Hispaniola, and Puerto Rico. They saw no Mexican specimens of this tree. This species is cultivated in southern Florida; it has been reported as locally naturalized (Barneby and Grimes 1996, Wunderlin 1998), but that is dubious.

Medicinally, *L. latisilicum* is considered tonic, febrifuge, and hemostat. The leaves in enemas have been used to stop prolonged diarrhea (Liogier 1974). There must be abundant tannins in the plants because they have also been used as a hemostat after childbirth (Morton 1981). A mixture of *Lysiloma*, mahogany (*Swietenia mahagoni*), and pine (*Pinus caribaea*) is combined with the roots of Hercules's club (*Zanthoxylum coriacea*) to treat the bleeding. The bark is also used in a complex mixture to treat gonorrhea (Morton 1981). The bark is made into a beverage in the Caicos Islands as a substitute for tea (*Thea sinensis*). Others in those islands recommend a bark tea of wild tamarind for "inward piles."

In Mexico, *L. acapulcensis*, *L. Candida*, *L. divaricata*, and *L. latisilicum* have been used for tanning leather (Uphof 1968, Alcorn 1984, Barneby and Grimes 1996). The Huastec of San Luis Potosi also use *L. acapulcensis* medicinally. Mostly, it is used to stop bleeding during childbirth, as *L. latisilicum* is used in the Bahamas, but also to treat sore gums, and pain from toothache, tooth decay, and tooth loss. For this purpose, it is made into a "tea" and used as a mouthwash, but it has the negative effect of darkening the teeth (Alcorn 1984). A decoction of the bark or root is also used to stop diarrhea. The same liquid is applied to external sores, rashes, and infected or incurable sores.

There are a number of gum exudates known for the genus (Anderson et al. 1990). Bark extracts from *Lysiloma* have antimicrobial activity (Pérez et al. 2001).

These trees are being used more in southern Florida as landscape plants, and the single tree that was planted near Palm Beach has been left standing beside a beachside condominium (ironically called "The Tamarind") that replaced the hammock there. Everywhere they are used they seem to thrive well north of their native range in the southernmost parts of the state. That ability to withstand cold makes me wonder if they are not comparatively recent arrivals to the flora of the peninsula. Perhaps current

cultivation of the species is simply speeding up the natural migration north that would have taken place without humans.

### *Lythrum*

(From Greek *lythron*, blood, gore, alluding to the color of the flowers, and probably to the use in stopping bleeding; a name used by Dioscorides for what is now called *Lythrum salicaria*)

***Lythrum alatum*.** From Britton and Brown 1897.

***Lythrum salicaria*** (an Old World species that influenced thinking about those in the New World)

*bouquet violet* (purple bouquet, Quebec)

*kattehale* (cat tail, Norwegian)

*lisimaquia roja* (red loosestrife, Spanish); *lysimachia* (from Greek *lysis*, a release from, and *mache*, strife, or from King Lysimachus of Thrace, the son of Agathocles; a name used by Pliny. According to tradition, the herb's virtues were discovered by Lysimachus who, when chased by a maddened bull, in desperation seized a plant of loosestrife and pacified the animal by waving the plant before him. The word was applied by Linnaeus to a totally distinct plant in the Primulaceae.)

[purple, spike] loosestrife (derived from *lysimachia*, ending strife)

*lus na siochaint* (plant of peace, Gaelic)

*salcerella* (little willow, Italian); *salicaire* (like a willow, French); *salicaria* (like a willow, Italian); *salqueirinha* (like a little willow, Portuguese); *Weiderich* (like a willow, German)

***Lythrum alatum*** (winged, the stems)

*caña* (cane, Mexico)

lance-leaved loosestrife (a translation of *L. alatum* var. *lanceolatum*)

milk willow  
 winged loosestrife [*lythrum*] (book name)  
*yerba del cancer* [*de México*] ([Mexican] cancer herb, Texas; the name  
 is usually applied to *L. californicum*)

*Lythrum salicaria* began as a medicinal plant imported from Europe into the Americas to relieve the suffering of settlers. That it apparently did, because it is still considered a useful herbal remedy by Foster and Duke (1990), Bown (1995), and Duke et al. (2002). Even the Iroquois adopted it and made a remedy to banish fever and sickness caused by being near the dead (Moerman 1998). Unhappily, the plant escaped into the wild and is devastating native American wetlands in the northeastern states by crowding out native plants. This is a blessing that has become a scourge (see Diggs et al. 1999).

Although these purple-flowered herbs had been discussed by many authors before Linnaeus ([1753] 1957), it was he who established the genus *Lythrum* as it is now used. He knew 7 species, 3 of them from the Americas, and the genus now contains 36 (Mabberley 1997). There are 13 species in Europe.

It was not until 1814 that Frederick Pursh named *L. alatum* in his *Flora Americana Septentrionalis* (Flora of North America). He had the plants from a wetland in Georgia. *Lythrum alatum* grows from northern New York to British Columbia, and south to Florida and Texas. The variety *lanceolatum*, sometimes considered a distinct species, grows from Florida to Texas, and from Virginia to Arkansas and Oklahoma.

Although *Lythrum* was a popular remedy in Europe (Fuchs 1542 in Meyer et al. 1999, Gerarde [1597] 1975, Culpeper 1563), there are few records of the plants being used by indigenous Americans. The Cherokees took an infusion of *L. alatum* for the kidneys (Hamel and Chiltoskey 1975). Elsewhere the plants are considered astringent, and they have been used to treat women's disorders. Hocking (1997) says that they have been used to treat cancer in Mexico, but that may be confusion with *L. californicum*.

# M

## *Madura*

(Thomas Nuttall named the genus for geologist William Maclure, 1763–1840; Maclure was born in Ayr, Scotland, and came to the United States in 1782; he visited Spanish Florida in 1817–1818 with ichthyologist Charles-Alexandre Lesueur, entomologist Thomas Say, lepidopterist Titian Ramsey Peale, and invertebrate zoologist George Ord)

*Madura pomifera*. From Sargent 1905.

*Madura pomifera* (bearing pomes or apples)

*ahilaknî* (yellow tree, Mikasuki); *eto lâne* [*'to lane, tola:nî, tulani*] (*eto*, tree, *lâne*, yellow, Muskogee); *itti' lakna* [*itti' laknani'*] (*itti'*, tree, *lakna*, yellow, Chickasaw)

*Bogenhoh* (bow wood, German); bow-wood (referring to this species, first found in the *Treasury of Botany*, published in 1866)

*bois d'arc* (bow wood, French); bodark [bodock, bodeck, bodare] (attempts to pronounce the French *bois d'arc*, Arkansas, Missouri)

*bois jaune* (yellow wood, from 1804 or before, cf. Jurney 1994); *geelhout* (yellow wood, Dutch); yellow-wood

hedge[-plant] (before the invention of barbed wire in the 1870s, these were the preferred hedge plants for fence rows; it met the farmer's criteria that a hedge must be "horse-high, bull-strong, and pig tight"; the legend is that the inventor of barbed wire took his inspiration from these plants and "put steel thorns" on twisted wire)

hedge-apple (originally applied by 1617 to crab apples and *Arbutus*; reapplied to *Madura* later)

horse-apple [horse apple] (horses and cattle eat the ripe fruits, sometimes to their detriment; occasionally the large fruits stick in their throats and kill them); did the English give rise to the Koasati name *có:ba intakkolá* (*co:ba*, horse, *in*, its, *takkolá*, peach), or was it vice versa?; *issobintakolo* (*issoba*, horse, *im+takolo*, its peach, Chickasaw)

*kamo* (Alabama); *ittokamo* (*itto*, tree, *kamo*, the *bois d'arc*, Alabama)

*min'-dse-shta-hi* (*min'-dse*, bow, *shta*, smooth, *hi*, wood, Osage); *zhon-çi min-dse hi* (*zhon*, wood, *çi*, yellow, *min'-dse*, bow, *hi*, tree, Osage); *zhonzi-zhu* (*zhon*, wood, *zi*, yellow, *zhu*, flesh, OmahaPonca)

mock orange [wild orange] (about the only similarity to an orange is that both are round; however, this folk-comparison persists)

*nakitsku* (Pawnee)

*naranjo chino [naranja China]* (Chinese orange, Texas, Mexico)

Osage (the Osage tribe spoke a Siouan language called *Dhegiha*, lived near the four-corners of southwest Missouri, southeast Kansas, north-east Oklahoma, and northwest Arkansas; these were the people with whom Hunter [1823] 1973 lived most of his early life); *Osage Dorn* (Osage thorn, German); Osage apple-tree; Osage-orange (the OED 1971 says in use since 1859, but Hunter was already using the name in 1823)

Ozark (this mispronunciation of *bois d'arc* finally gave the name to the Ozark Mountains, Missouri, cf. Steyermark 1963)

rootwood

*zaip-gwawt-'ko-ya-daw* (Kiowa)

*Maclura* grows in a few spots around Tallahassee (Leon County) and Marianna (Jackson County) (Kurz and Godfrey 1962). What is remarkable about those groves is that they are at least 700 miles east of what is considered the native range of the species (Little 1971, Jurney 1994). It is obvious that humans brought the plants to Florida. What is not clear is which group of people and in what time period.

Osage-orange is native to the homelands of the Caddo, Wichita, and Tonkawa, but not the Osage. Perhaps it was because of their bellicose nature that people associated *Maclura* with the Osage. However, the Osage and the Quapaw spoke the same language so perhaps they formerly were considered the same by settlers (Rankin 1988). The Caddo traded the wood with their neighbors, and the Quapaw took it as far east as the junction of the Arkansas and Mississippi Rivers in what is now southeastern Arkansas (Swanton 1946). To the west, this valuable resource was trafficked at least as far as the Tewa Pueblo in northcentral New Mexico. However, the bow-wood was in demand even farther from its homelands.

The Arikara of South Dakota, the Blackfoot of northwestern Montana, and the Kiowa of northcentral Oklahoma also prized the tree as bow-wood (Peattie 1953). In 1810, the Scottish traveler John Bradbury found the Arikara using *bois d'arc* bows. They valued them so much that a bow of the wood was worth a horse and a blanket. Shortly afterward, Prince Maximilian of Wied-Neuwied found the Blackfoot coveting the bows that they had acquired through barter. As late as 1853, after all individuals who could had switched to guns, the Kiowa met Lieutenant Whipple on the *Llano Estacado* of New Mexico. He wrote, "They carried superb bows of *bois d'arc*, ornamented with brass nails, silver plates, and wampum beads."

When they could get it, the Yuchi (along the Tennessee River in what is now eastern Tennessee) and the Taskigi or Tuskegee Creeks (on the Tennessee River in northeastern Alabama) used the wood for making bows (Swanton 1946). The Alabama also used the wood to make utensils and tools. Knowledge of *Maclura* wood spread throughout the southeastern United States.

The first European contact with the region where this wood originated was made by Jacques Marquette and Louis Joliet [Jolliet] between 1673 and 1675. The two traveled down the Mississippi River to its junction with the Arkansas River. There they met the Quapaw, who had for so long been instrumental in trading *Maclura* wood farther east. Following this expedition, the French sent settlers into the area, and René-Robert C. Sieur de La Salle created the first settlement near what is now Peoria on the Illinois River. Later, in 1699, Cahokia was founded east of modern St. Louis and named after a tribe it supplanted there. It was not until 1764 that Pierre Laclède Liguest established the beginnings of St. Louis. By that time, French trappers and other travelers had traversed much of the region learning about its natural resources, and the name *bois d'arc* had become established.

By the late 1700s, Americans were well aware of *bois d'arc* and its uses, but they had comparatively little information on the wild plants. At the time of the Louisiana Purchase in 1804, John Sibley and Merriwether Lewis reported to President Jefferson on *bois d'arc*. Based on the information they had, they concluded that the main source of trees was on the Red River in Oklahoma and Arkansas (Jurney 1994). At that time, the Caddo still maintained a lively trade among Plains and southeastern tribes for the wood. The Dunbar and Hunter expedition was sent in 1804–1805 to gather more data. They went along the Ouachita River in south-central Arkansas and found only trees that had been planted from more distant sources.

Peter Custis found a transplanted *bois d'arc* within 1 mile of Natchitoches, Louisiana, in 1806 (Jurney 1994). At the time, that was the known southeastern limit of cultivation of the species. The tree had been brought there from the Red River in southwestern Arkansas. Custis even found that there was a stream locally called “Bois d'Arc River” that fed into the Red River in southeastern Oklahoma. He thought that all occurrences of the tree east of that region were where it had been planted around old Caddo villages.

Anthony Glass, traveling overland from Natchitoches to the Wichita villages on the upper Red River in 1807, observed what he took to be native stands of *Maclura*. One site was in what is now Lamar County, and the other was in Fannin County, Texas. The second site was known as “Bois d'Arc Creek” and Glass was told by French trappers that it was a favorite beaver stream. He claimed that the Wichitas made bows of it with which “arrows were propelled completely through bison” (Jurney 1994). Other tribes who used the wood for bows included the Comanche, Omaha, Pawnee, Pima, Ponca, Seminoles, and Tewa (Gilmore 1919, Sturtevant 1955, Moerman 1998). Modern Cherokee in Oklahoma still prize the wood for bows, although no direct evidence has been found that they knew about the wood before they were removed from the Carolinas (Herrin 1999).

The sapwood of Osage-orange is narrow and light yellow, while the heartwood is golden to bright orange, and darkens upon exposure. The heartwood can also contain red streaks. The wood is hard, heavy, tough, resilient, and has a high luster when polished; it is ring porous and commonly confused with black locust (*Robinia pseudoacacia*) (Alden 1994b). In addition to bows, it has been used for fuel, fence posts, game calls, smoking pipes, artificial limbs, crutches, insulator pins, wheel rims and hubs of farm wagons, railroad ties, tree nails, and machinery parts. Wood from the trees is considered one of the woods most resistant to decay in North America (Diggs et al. 1999).

One of the driving forces for the Dunbar and Hunter expedition was the potential of the tree as a commercial dye. Hunter wrote in 1805 that *Madura* “is more frequently

called *Bois jaune* (Yellow Wood) [and] used by them [Caddo] and the inhabitants as a dye” (Jurney 1994). The Kiowa and Pima also used it for that purpose (Moerman 1998). Sargent (1905) identified the chemicals responsible for the dye as moric or moritannic acid. Cannon and Cannon (2003) say that the responsible chemicals are morin, a flavonol in the wood, while the fruits have isoflavones osajin and pomiferin. The dried, chipped wood is still available from dye suppliers in the United States and Europe. The bark has an orange cast, and it was used to make khaki dye during World War I; it is still used for that purpose today (Hocking 1997).

Much less known is that fiber from the bark has been used by indigenous tribes. Gilmore (1931) found cords made of *Maclura* at the Ozark Bluff-Dweller site in Arkansas.

Hunter ([1823] 1973), who had lived with the Osage most of his life, listed the species along with a series of edible fruits (plums, strawberries, gooseberries, whortleberries, blackberries, and grapes). That seems to imply that the Osage also ate the fruits, but no other record of edibility has been found.

The only record of medical use of these plants seems to be among the Comanche who made the roots into an eyewash (Vogel 1970). Any use is surprising because of the irritating compounds in the family, but especially in the latex. Some people develop dermatitis from contact with the latex, leaves, or fruits (Diggs et al. 1999). Fruits contain lupeol and lurenol mixed with some related chemicals; woods have morin and maclurin (Hocking 1997). George M. Toffel, of the University of Alabama, found in the 1940s that a single *Maclura* fruit in a room will drive away cockroaches. He attributed that to the cedar-like odor of the chemicals in these multiple fruits (Peattie 1953).

The only truly modern indigenous use appears to be among the Oklahoma Seminoles. There Howard (1984) found interesting views about the plants. He recorded that at least some individuals believed that a person contemplating a journey should get four spines from a *tulani*. Those spines are to be put under the hatband in front of the traveler’s hat while facing the direction of intended travel. That action will cause dangerous snakes to move from the traveler’s path. In the rocky hill country of Oklahoma where rattlesnakes are abundant, that might be an important piece of woods-lore.

### *Magnolia*

(Linnaeus adopted the genus proposed by Charles Plumier for these plants in 1703; named after the Frenchman Pierre Magnol, 1638–1715, an innovator in classification and director of the botanical garden in Montpellier)

*Magnolia acuminata* (pointed, the leaves)

*chawpesha* (bitter, Osage)

cucumber tree [cowcumber tree] (a comparison of the fruits to those of *Cucumis sativus*; a name used in print by Thomas Jefferson in 1806; also used by Hunter [1823] 1973)

*sha-ga-shingah* (*sha*’-ge, fingers, *zhin-ga*’, little, Osage)

*Magnolia grandiflora* (large-flowered)

bull-bay [bull bay]

***Magnolia virginiana*** a. a. Branch with flower, b. Fruit. Drawn by Vivian Frazier. From Correll and Correll 1972.

great laurel magnolia (“magnolia” as a word in English dates from about 1748)

*hi’lañ te nec* (hílan, vulture, *te*, plural, *nee*, tree, Atakapa)

*kafàaha* [kafààha] (Alabama); *kolaha* [katlaha] (Choctaw)

*kokayudi* [okayudi] (Biloxi)

loblolly [southern] magnolia (“loblolly” alludes to the trees growing in wet ponded areas and other swamps)

*tolacobá* (tolá, bay, *cobá*, large, Koasati)

***Magnolia macrophylla*** (large-leaved)

[large-leaved] cucumber tree

***Magnolia pyramidata*** (pyramid-shaped or triangular-leaved)

Bartram’s magnolia (so called because Bartram described the species in [1791] 1958)

mountain [pyramid] magnolia

southern cucumber tree

wood oread (the oreads were mountain and hill nymphs in Greek mythology)

***Magnolia tripetala*** (three-petaled)

elkwood

umbrella tree

***Magnolia virginiana*** (from Virginia)

*awúxú 'xkudi'* (Biloxi)

beaver-tree (recorded by Kalm in the 1740s; said to be called that “because the root of this tree is the dainty of beavers,” *Castor canadensis*, and these animals taste best if they had eaten the bark)

Indian bark

*kałàaha*

*kalaha* [*katlaha*] (Choctaw); *hatka* (white bay, Alabama)

*laurier* (laurel tree, Houma, Louisiana)

*okeetosku* [*oketoksu*] (sour water, Hitichiti)

swamp bay [laurel, magnolia]

swamp sassafras (Kalm [1753–1761] 1972)

sweet [sweet-flowering, white] bay (Catesby found it being called “sweet-flowering bay” in the 1720s)

*to:lahá:tká* (white bay, Creek); *tó:lhátí* [*too-latkee*] (white bay, Mikasuki); *tola* (Timucua); *tolaliocko* (Creek, used by Simmons [1822] 1973); *tolochlucco* (big bay, Creek); *tolá hátka* (*tolá*, bay, *hátka*, white, Creek)

white laurel (Kalm [1753–1761] 1972)

William Bartram ([1791] 1958) wrote about finding seven species of *Magnolia* in his *Travels*. Those species were *M. acuminata*, *M. fraseri*, *M. grandiflora*, *M. macrophylla*, *M. pyramidata*, *M. tripetala*, and *M. virginiana* (Harper 1958). In other words, he missed only one species in the southeastern United States, *M. ashei* (Kartesz 1994). Perhaps it is not surprising that he gave more space to *M. virginiana* than any other because that species was favored by indigenous tribes.

The Cherokee used *M. acuminata* and *M. macrophylla* wood for furniture and building. They used the wood of *M. virginiana* for skewers for cooking meat, to add a sweetish flavor. Oddly, there seem to be no records of other tribes using the wood from these plants. Porcher (1863) wrote that *M. acuminata* “is soft, fine grained, and susceptible of a brilliant polish. It is sometimes sawed into boards, and used in the interior of wooden houses.”

The most common application of the trees seems to have been medicinal. The Cherokees took an infusion of *M. acuminata* bark for stomachache or cramps, diarrhea, toothache, indigestion, and sinus trouble (Hamel and Chiltoskey 1975). The Iroquois, Kansas, and Osage used the fruit and bark to expel intestinal worms (Hunter [1823] 1973, Moerman 1998).

Bernard Romans ([1775] 1961) extolled the virtues of the root bark of “*Magnolia major*,” presumably *M. acuminata*, mixed with other herbs in wine as a bitter infusion to treat malaria. Physician Johann D. Schopf, after visiting North America in 1783–1784, recommended both *M. acuminata* and *M. virginiana* to treat diarrhea, cough,

tuberculosis, and fever (Vogel 1970). Andre Michaux wrote in 1802 that frontiersmen infused cones of *M. acuminata* in whiskey as a bitter drink to relieve malaria (Vogel 1970).

Porcher (1863) wrote that *M. acuminata* cones were “being employed in the form of a spirituous tincture in rheumatic affections. Used as a prophylactic in autumnal fevers. The flowers of most magnolias exhale a strong aromatic fragrance; the bark of all possesses a combination of bitter and hotly aromatic properties, without astringency, and that of many acts as a powerful medicine, in a similar way to Peruvian bark and Winter’s bark.” Hocking (1997) recorded that the bark of *M. acuminata* had been used as a bitter tonic, against fever, rheumatism, vermifuge, and indigestion.

The Choctaw washed with a decoction of *M. grandiflora* bark to relieve the itching of prickly heat, and made a drink or bath for dropsy (Bushnell 1909). The Koasati washed sores with bark (Taylor 1940).

Physician Benjamin Barton declared in 1793 that *M. grandiflora* mixed with “snakeroot” was a substitute in Florida for quinine in treating malaria (Vogel 1970).

Porcher (1863) wrote of *M. grandiflora*: “The medicinal and chemical properties of [*M. virginiana* and *M. grandiflora*] are supposed to be identical. Mr. Proctor...found in this species volatile oil, resin, and a crystallizable principle analogous to the liriodendrine of Prof. Emmet, obtained from the *L. tulipifera* growing in this state (see *Liriodendron*)...in Mexico the seeds are employed with success in paralysis.” Bark of *M. grandiflora* was used to treat malaria, rheumatism, and bitter tonic. Seeds have fatty oils used in soap manufacture (Hocking 1997). People in Veracruz still use it as a tonic (Vasquez and Jacome 1997).

The Cherokee made an infusion of *M. macrophylla* bark for stomachache or cramps, diarrhea, toothache, indigestion, and sinus trouble (Hamel and Chiltoskey 1975). Regarding *M. macrophylla*, Bartram wrote to his friend Robert Barclay some time before his book was published in 1791: “I shall just observe that I discovered, in the Creek Nation & Wt. Of Georgia a Species of *Magnolia (auriculata)* very different from Mr. Frazers. The leaves of which were very large near 2 feet in length, the Flowers, white, Very large, & Fragrant & the Strobile or Seed Vessels 4.5 inches in length of a fine Crimson Color.”

Porcher (1863) thought that *M. macrophylla* had the same properties as *M. virginiana*. All Hocking (1997) said was that it was used medicinally.

No records have been found of indigenous tribes using either *M. pyramidata* or *M. tripetala*. However, Hocking (1997) considered the bark of *M. pyramidata* tonic and astringent. Porcher (1863) thought that *M. tripetala* “acts so powerfully on the nerves as to induce sickness and headache.” In spite of that view, or

*Acoelorrhaphe wrightii*—This is the “Everglades palm” (Florida), *chi-it* (Yucatán), or *guano prieto* (Cuba). The leaves are used for thatch and rope, and the stems are used in construction. (See p. 63.)

*Alvaradoa amorphoides*—In Yucatan, this tree is the *belcini-ché* to the Maya and palo de hormigas to others. The wood is prized, and the bark and leaves are medicinal. Prehistoric people may have introduced the species into Florida. Photo by T.R. Van Devender. (See p. 77.)

*Agave decipiens*—“False sisal” was probably used for fiber and medicine by the Glades people like its Mexican relative *A. angustifolia*. The Seminoles call it *pasalátkico:bî* (big yucca, Mikasuki). (See p. 68.)

*Annona glabra*—“Pond apple” fruit pulp is edible but not particularly good. The wood is made into corks, but seeds, bark, and leaves are medicinal. The Seminoles call the species *etotakwe* (hollow tree, Creek). (See p. 95.)

*Asimina triloba*—“Pawpaw” fruit pulp is edible, and the bark was an important fiber source. Two places in Georgia are called “Alcovy,” which was derived from the 19th century Creek name *Ulco-fau-hatchee* (pawpaw thicket river). (See p. 122.)

*Aster carolinianus*—The Miccosukees call the “climbing aster” the *wahó:tlintayhî* (water moccasin’s bed) and use it to treat Snake Sickness. (See p. 126.)

*Asplenium erosum*—"Eared spleenwort" or *culantrillo* was mixed with several other ferns and used in baths to reduce fever. (See p. 124.)

*Campsis radicans*—The Chickasaw call these vines *ampohko 'li'*. A remedy made from the root helps reduce fever and heal wounds. Usually it is called "trumpet vine," but some know it as "cow itch." (See p. 160.)

***Cannaflacdda***—This herb has hard, black seeds that the Seminoles call *sawakmalî:tî* (Mikasuki) and *sáwko matihita* (Creek), both meaning “rattle’s contents.” The settlers called this “bird-shot” or “Indian shot” because seeds were substitute bullets in muzzle-loading guns. (See p. 164.)

***Capsicum annuum***—The Taino of Cuba called the fruits *aji*, and that became one Spanish word for red peppers as far away as Peru. Fruits were *chilli* to the Aztecs, and that too was adopted into Spanish and English as “chile.” (See p. 168.)

***Capparis flexuosa***—The Maya call this shrub *bokanche*’ or “tree that looks like a viper’s skin.” The Haitians say *bois rave* (enrapture tree). Both Florida species provide a mustard substitute. (See p. 164.)

***Carphephorus corymbosus***—“Paint-brush” is considered a urinary antiseptic. More famous is “deer tongue” or “vanilla leaf.” The leaves have been used as medicine and to flavor tobacco and perfumes. (See p. 174.)

***Carya floridana***—*Pawcohiccora*, a name used by the Powhatan of coastal Virginia, became “hickory” in English. *Carya* was so important as a food and for wood that some species have distinct Creek names, as in *penossy*, *oce-tofky*, and *oce-cvpkce*. (See p. 176.)

***Chiococca parvifolia***—Medicine made from “snow berry” or “skunk root” has been used as a purgative and to treat asthma, expel gas, lower fever, and ease menstrual cramps. A preparation in Belize also helps alcoholics stop drinking. (Seep. 201.)

*Cephalanthus occidentalis*—The Miccosukee call these shrubs *halpáti:hosó:tí* (alligator shader); the Creeks say *sakco'meto* (crawfish's tree). Although the remedy may be lethal, this has been an important medicinal plant throughout its range. (See p. 190.)

*Chromolaena odorata*—“Bitter bush,” “Christmas rose,” and *fleurit-Noël* are all names for this herb. The plant is either a fish poison or medicine, depending on how the preparation is concocted. (See p. 204.)

***Cordia sebestena***—Artist Mark Catesby reported in the 1730s that the wood “contains much Gum, in Smell and Appearance resembling Aloes, and is by the Inhabitants of the Bahama Islands (where it grows) called *Lignum Aloes*.” (See p. 239.)

***Cucurbita okeechobeensis***—The wild “Okeechobee gourd” is *ciko:yi* (Mikasuki) to the Seminoles. *Coksî* is their generic name for the cultivated *Cucurbita*, and that has cognates in Creek (*chasi*), Alabama (*choksi*) and Chickasaw (*lokosh*). Photo by Terrance Walters. (See p. 251.)

***Cornus foemina***—Englishman Philip Miller considered this a “female” species as opposed to the “male” (*C. florida*). The Creeks call the shrubs *vtvphv*, pronounced “*atápha*” (See p. 241.)

***Drosera tracyi***—Gaelic-speakers call their “sundews” the *lus na greih* (sun plant). The Miccosukees treat ringworm with the herbs and call them *oláyikcî* (ringworm medicine). (See p. 276.)

*Echinacea purpurea*—Modern herb collectors make no distinction between the species of “purple coneflowers” and put them all in the same gathering. The Choctaw chewed the roots to relieve coughing. (See p. 279.)

*Euthamia graminifolia*—“Flat-top goldenrod” was used to treat chest pains and lower fever. The Ojibwa smoked the flowers as a hunting lure, saying that the odor simulated the smell of a deer’s hoof. (See p. 299.)

***Eupatorium capillifolium***—The Cubans call this herb *copal* (incense), and many English speakers say “dog fennel.” This species and *E. compositifolium* are notoriously fragrant, and their herbage strewn on floors is insecticidal. (See p. 296.)

***Evolvulus sericeus***—This species, *hauay ak* (leprosy vine) to the Maya, yields a medicine to treat burns. The Mayas call the related *E. alsinoides* the *sian xiw* (enchantment herb) and use it to treat mental problems. (See p. 301.)

***Hypelete trifoliata***—Known as *hueso de costa* (coastal bone), the wood is valued in the Caribbean. (See p. 42.)

***Ipomoea pes-caprae***—“Goat’s foot” or *riñonina* (little kidney) contains compounds as effective as Benadryl® in treating insect stings and bites. (See p. 366.)

***Illidum floridanum***—This plant is called “stink bush” or “purple anise.” The flowers and crushed leaves smell like dead fish, but the bark is an aromatic tonic. (See p. 42.)

***Liatris tenuifolia***—The Creeks call several species *ico imaha* (deer’s potato). The Creeks, Seminoles, and other southeastern people make medicine from the roots. (See p. 403.)

***Lycium carolinianum***—These are either a “wolf-berry” or “Christmas berry,” depending on the speaker. Birds eat the fruits, and so can people, but *Lycium* specialist Fernando Chiang says they are not likely to replace cherry tomatoes. (See p. 416.)

***Monarda punctata***—The Creeks know these mints as *kofucka rakko* (strong fragrance). They and other tribes in the East made a number of medicines from them. (See p. 443.)

***Magnolia triapetala***—The Timucua called the genus *tola*. The Seminoles used the same name, with modifiers added to distinguish species, as in *tó:lhátki* (Mikasuki) and *to:lahá: tka* (Creek), both meaning “white bay,” for *M. virginiana*. (See p. 425.)

***Morinda royoc***—“Cheeseweed” has ripe fruits that smell like hot limberger cheese; the Jamaicans call it “duppy poison.” Also called “yaw weed,” the shrub was famous for treating that terrible malady by the 19th century. The plant is a source of yellow to red dye. (See p. 444.)

*Nyssa ogeche*—The species was first found by John and William Bartram in October 1765. William later wrote, “... they are called Ogeche limes, from their acid fruit being about the size of limes, and their being sometimes used in their stead.” (See p. 460.)

*Passiflora incarnata*—Writing in 1612 on the James River of Virginia, William Strachey considered, “The *Maricock* apple, of the bigness of a green apple, and hath manie azurine or blew kernells, like as a pomegranate, a good sommer cooling fruit.” (See p. 483.)

***Opuntia humifma***—John Harriot wrote in the 1580s that “prickly pears” to the Carolina Algonquians were *metaqvesvnnavk*. In some places, they were so abundant from indigenous use that William DeBrahm, who surveyed the Florida coast in the 1760s, thought that cochineal insects might be grown on them as a source of red dye. (See p. 465.)

***Peperomia obtusifolia***—These wild peppers are used in medicines throughout much of their tropical range. (See p. 490.)

***Phyla stoechadifolia***—This “fog-fruit,” endangered in Florida, is sacred to the Maya. They call it *kabalyaxmik*, a name referring to the herb’s important place at the base of the *ya’ax che’* (green tree, *Ceiba pentandra*) that supports the world. (Seep. 501.)

***Pilocereus robinii***—This tree cactus of the Florida Keys has edible fruits much like those of the more famous saguaro (*Carnegeia gigantea*) of northwestern Mexico and adjacent Arizona. (See p. 43.)

***Piloblephis rigida***—This is *hapo:sikâ:yî* or *haposhekaayechoobe* (Mikasuki) and *kyfockv* (Creek). Seminole Alice Snow said: “My mother told us if you have a cold you could smell this. It was good smelling, so we would smell it all the time.” (See p. 511.)

***Pinguicula lutea***—The Seminoles call this herb *la:nihiliswâ* (yellow medicine, Creek) or *talakcihcaiyikî* (raw medicine, Mikasuki). They use it to treat digestive problems. (See p. 512.)

***Piscidia piscipula***—The scientific name means “fish-poison for little fish.” The tree is also “fish-fuddle” (USA, Jamaica), “fish-poison” (Florida to Panama), *morta [à] poissons* (Lesser Antilles), and *matapez* (Mexico, Colombia). The bark is medicinal. (See p. 514.)

***Platanthera ciliaris***—The Cherokee put roots of these orchids on hooks to make fish bite, but it only worked if they knew the proper song and spat on the hook. (See p. 522.)

***Pisonia aculeata***—Although it is now called “devil’s claw,” these spiny climbers were known as “blaspheme vine” in the early 20th century. The branches were made into barrel hoops and medicines. (See p. 516.)

***Pluchea rosea***—“Camphor-weed” is mixed with other plants in the Bahamas to reduce labor pain. The Choctaw thought *P. foetida* was a *hoshukkosona* (strong smell grass) and used it for treat fevers. (See p. 525.)

***Plumbago scandens***—There is an ambiguity toward these plants typified by the name *homme [à] deux faces* (man with two faces, Haiti). The herbs are pretty because of their flowers, but they are acrid, blistering, emetic, and medicinal. (See p. 527.)

***Psychotria sulzneri***—This hammock shrub is known to the Seminoles as *atópâ:bî* (dogwood replica, Mikasuki). (See p. 547.)

*Polygala boykinii*—“Milkworts” are widely believed to induce milk flow in animals and humans. *Polygala*’s religious significance in Florida is indicated by the Miccosukee name *sápiyâ:bî* (resembling the mythical plant “*svpeyv*”). (Seep. 532.)

*Quercus laevis*—Acorns were so important to indigenous people that there is a river in central Florida the Timucua called *ajano hibita chirico* (river of little acorns). The Seminoles call one site *lokcha apopka* (place for eating acorns, Creek). (See p. 558.)

***Rhizophora mangle***—A European wrote in 1613 about a “tree called Mangrowes, they grow very strangely, & would make a man wonder to see the manner of their growing.” The Seminoles call them *ahilo:ckitiscî* (Mikasuki) and *tolastica:tî* (Creek). (See p. 569.)

***Sabatia bartramii***—“Rose-pinks” are *kococompahá:ka* (Creek) or *owa:ciká:bî* (Mikasuki) to the Seminoles. Both names mean “star replica.” They use one species to treat *Ha:sthlayhi* (Sun Sickness), a malady that strikes in the hot months of May through August. (See p. 587.)

***Sabal palmetto***—These are *ta:larákko* (Creek) or *talcó:bî* (Mikasuki), both meaning “big palm.” Fibers from the leaves were traded north to the Winnebago of southern Wisconsin and Iroquois of New York, 600–700 miles north of the closest “cabbage palm” stands. (See p. 585.)

***Sarracenia minor***—Many indigenous tribes considered pitcher plants medicinal. “Hooded pitcher plant” is also called “smallpox plant” because it was used to treat smallpox and other skin rashes and eruptions. (See p. 603.)

***Saururus cernuus***—Indigenous American names include *ishuna ignone* (Choctaw), *oyihiliswa* (Creek), and *yahkakayikci* (Mikasuki). The Seminole names mean “widow or widower medicine” because it is used to help the bereaved get over their loss. (See p. 608.)

***Stachys floridana***—“Florida betony,” like other perennial species in *Stachys*, has edible tubers. John Lightfoot wrote of *S. palustris* in 1777 that they were “sweet, and in times of necessity...eaten by men, either boiled, or dry’d, and made into bread.” (See p. 645.)

*Spartina bakeri*—Calusas living on Marco Island, Florida, thatched their houses with “cord grass” before the Europeans arrived. (See p. 640.)

*Stillingia sylvatica*—Because the stems have milky juice, the Seminoles call this plant *owa:ctafânkî* (milky center, Mikasuki) or *pisi:ká:fkatî:ko* (pliable breast milking, Creek). A decoction is taken to treat diarrhea, vomiting, and appetite loss. (See p. 650.)

***Strumpfia maritima***—“Pride-of-Big-Pine” (Florida), also called *romero falso* (false rosemary, Cuba), is a stimulant and is used to treat bites of poisonous animals; a stronger decoction permanently sterilizes women. (See p. 652.)

***Tournefortia hirsutissima***—The Seminoles call the climber *cokashatki* (*white* grapevine, Mikasuki) or *coloifákâ* (grapevine cord, Creek). The Caribbean name “chiggery grapes” is used because some people treat itching chigger bites with the leaves. (See p. 675.)

***Torreya taxifolia***—Known as “stinking cedar” in the Panhandle, the wood was made into fence posts. Now the Florida endemic is globally endangered and too rare to harvest. Photo by David Neubauer. (See p. 674.)

***Trema micrantha***—To the Taino of Cuba, the “Nettle Tree” was *majagua*, and *cabuya* was their word for cords made from the bark. The Seminoles know the plants as *sili: iá:pî* (Mikasuki) or *lipá:pín* (Creek), slimy stem. People and birds eat the fruits. (See p. 679.)

*Tripsacum floridanum*—From at least the time of the preColumbian Ozark Bluff-Dwellers of Arkansas, seeds of *T. dactyloides* have been eaten raw or popped like popcorn. *Tripsacum floridanum* provides a local southern Florida alternative. (See p. 686.)

*Zanthoxylum fagara*—Creek-speaking Seminoles call the tree *tofvske*, and the Miccosukee say *caháhtí*. They used the wood for bows and arrows. Many people use various parts of the plant for food, medicines, and dyes. (See p. 725.)

*Vitis shuttleworthii*—The Miccosukee call this grape *balbe* or *cokasi*. The name in Creek is *patko*. Grapes were an important food to indigenous people, and the stems were a source of emergency drinking water. It is hard to beat wildlife to these sweet fruits. (See p. 707.)

*Zephyranthes simpsonii*—“Rain lilies” appear suddenly after spring and summer rains. That sudden emergence has led to names like *brujita* (little witch), and *duende* (little devil), “fairy-lilies,” and “Zephyr-lilies.” The Seminoles used *Zephyranthes* as an analgesic against toothache. (See p. 733.)

perhaps because of it, *M. tripetala* was formerly in the U.S. Pharmacopoeia (Hocking 1997).

Because *M. virginiana* grows from Massachusetts southward along the coast to Florida and west to Texas, it is associated with several other species used by indigenous people. The Rappahannock in Virginia have been reported to use *M. virginiana* as a stimulant or “mild dope” (Moerman 1998), although that seems unlikely. Regardless, the Choctaw and Houma used the leaves and twigs to “warm the blood,” and the same decoction was used to treat colds (Bushnell 1909, Speck 1941, Vogel 1970). The Biloxi of Louisiana made a tea from bark and leaves and used it to promote perspiration (Dorsey and Swanton 1912). Probably the use of *Magnolia* is underreported because it shares the common name *tola* with *Persea* and *Ocotea*.

*Tó:lhátki* is an important ingredient in the ceremony for the annual Seminole Busk festival (Sturtevant 1955). The Choctaw probably used it in the same way because they applied the same name (Bushnell 1909).

*Magnolia virginiana* became important to Americans who put the bark in brandy as a cough medicine, and used the liquid to treat fevers, diarrhea, dysentery, colds, rheumatism, and malaria, and for other uses similar to *M. acuminata* (Millspaugh 1892, Vogel 1970, Hocking 1997). Peter Kalm ([1753–1761] 1972) wrote, “The virtues of this remedy are universally extolled.” He went on to note that the bark eased chest problems, internal pains, fever, dysentery, and colds. Externally, it was equally valuable. An elderly Swedish settler whom Kalm met had been afflicted with stubborn leg sores that were healed by a native (Delaware?) who used the wood of *M. virginiana*. The wood was burned down to charcoal, ground down to powder, mixed with fat, and rubbed on the open sores. Kalm reported that the remedy, “Dried up the holes, which before were continually open.” Physician Benjamin Barton wrote in 1793 that *M. virginiana* was a favored remedy among the “Indians of the Kanawha River” (Tutelo tribe, Siouan language stock) of West Virginia where it was used to treat rheumatism and fevers (Vogel 1970). Barton’s student Thomas D. Page wrote a dissertation on *M. virginiana* in 1802.

In Millspaugh’s (1892) time, the bark was considered a bitter aromatic tonic, febrifuge, diaphoretic, antiperiodic, and gentle laxative. It was recommended for “acute coryzas, bronchial catarrhs, chronic rheumatism, dyspepsia, remittent and intermittent fevers and typhoid states.”

*Magnolia* spp. were in the U.S. Pharmacopoeia from 1820 to 1894 (Vogel 1970). The recommended use was largely for intermittent fever (malaria) and rheumatism (Bown 1995). Duke et al. (2002) list only *M. virginiana*, which they said has been used as an anti-inflammatory, cardioactive, diaphoretic, stimulant, and tonic. They recommend it with two plusses (as safe as a cup of coffee) for chills, colds, dyspepsia, epilepsy, fever, gastrosis, inflammation, malaria, rheumatism, and typhoid.

*Magnolia* in the Americas contains salicifoline and magnoflorine (Hocking 1997), and Porcher (1863) said that it also contained liriodendrine. In Asia, *M. officinalis* contains magnocurarine, a chemical similar to the muscle relaxant curare (Bown 1995).

***Maianthemum***

(From Latin *mains*, May, and Greek *anthemon*, flower)

***Maianthemum racemosum*. From  
Britton and Brown 1896.**

***Maianthemum racemosum*** (having flowers in a raceme)

*agoñgosi' minaga'wic* (chipmunk berries [with] little wood, Potawatomi)

false [wild] lily-of-the-valley (“lily-of-the-valley” is a literal translation of *lilium convallium*, which itself is a literal translation of the Hebrew phrase; applied in Europe by British herbalist Turner in 1538)

*muguet* (from *noix muguette*, in turn from *noix muscade*, nutmeg, although the relationship is obscure, Quebec)

*Schattenblume* (shade bloom, German)

scurvy-berries

[clustered, false, feather, feathery, large, twoleaved, zig-zag]  
Solomon’s seal (“Solomon’s seal” is translated from Latin *sigillum Solomonis*; used in English by 1526 in the *Grete Herball*, for *Polygonatum*); Solomon’s plume [zigzag]

[American, wild, false] spikenard (“spikenard” is derived from Latin *spica*, spike, plus *nardi*, aromatic resin; an aromatic substance employed in Roman times in the preparation of a costly ointment or oil, originally made from *Nardostachys grandiflora*, Valerianaceae or Caprifoliaceae; used in English by A.D. 1350)

treacle-berries (“treacle” combines the old pharmaceutical sense, an antidote against venomous bites, and sweet; the first dates to about A.D. 1200 in Old French, *triacle*, and 1340 in Middle English, *trya’cle*; OED 1971 says the sense of sweet dates from 1694, but earlier in Josselyn 1672, see below)

Europeans were well acquainted with Solomon’s seal (see *Polygonatum*) when they arrived in the New World, and here they found different but similar new herbs. Scientists back in Europe did not know what to do with the plants. Linnaeus thought they were like lily-of-the-valley and called them *Convallaria racemosum*. Later René L.Desfontaines

(1750–1833) decided they were in a related genus and called them *Smilacina racemosa*. That genus was a diminutive form of *Smilax*, indicating another similarity. Finally, in 1821, Johann H.F. Link (1767–1851) created the name now in use. The common names parallel the confusion among the scientists and compare the herbs to the same Old World plants.

American people used these herbs as medicines, but not like Solomon's seal had been used in Europe. Records have been found of many indigenous eastern tribes using American spikenard, but none for the Muskogean tribes. Their allies the Cherokee treated sore eyes with a cold infusion of roots (Hamel and Chiltoskey 1975).

Moerman (1998) recorded uses by other eastern tribes. The Abenaki used a decoction to stop bleeding in the lungs. The Algonquin used an infusion to wash back sores. The Delaware considered the herbs tonic. The Iroquois drank infusions with or without whiskey after miscarriages, to expel tapeworms, counteract poison, and relieve rheumatism. They also used it externally to soak sore feet, on swollen areas, and on snakebite. The Malecite and Micmac used an infusion to heal rashes and itching. The Menomini inhaled steam from it to relieve catarrh. The Meskwaki used it as a calnative and to loosen bowels. They also included it in several preparations to aid or divert magic. The Mohegan used it in cough medicine, for stomach problems, and as a spring tonic. The Ojibwa applied a root decoction or poultice to cuts, to relieve back pain, headache, and sore throat. They also considered it diuretic. The Potawatomi helped revive comatose patients with it (Smith 1933).

The Ojibwa also considered the roots edible, soaking them in lye to remove the bitter taste, parboiling, and then cooking them like potatoes (Fernald et al. 1958). Porcher (1863) noted that *Maianthemum* growing in the Confederate States “yield starch from their roots.” Even when Fernald et al. (1958) were considering them as food plants, they cautioned that the herb was so uncommon it was “unwise to draw upon it when other vegetable food is available.”

John Josselyn, writing of New England in 1672, recorded that berries were “called treacle-berries,—having the perfect taste of treacle when they are ripe. ... Certainly a very wholesome berry, and medicinal.” Fernald et al. (1958) added that the fruits are “bittersweet, suggesting bitter molasses, but they are cathartic and should be eaten with caution.”

### *Malus*

(From Latin *mains*, an apple, Greek *malea* or *melts*; akin to Akkadian *malum*, to be full, Hebrew *male*, full) *abhal*, *ubhal* (Irish); *abhall*, *ubhal* (Gaelic); *aeppli* (Old Swedish); *afal* (Welsh); *apel* (Dutch); *Apfel* (apple, German); *aval* (French); apple (from Old English *appel*, the fruit, appearing about A.D. 885; akin to *aepplas*, of the eye, but it is not clear which is the earlier application, the fruit or the eye; suggestive is the Gaelic expression *clach-nasula* [stone of the eye], which means the apple or the pupil of the eye; de Candolle suggested in 1886 that “apple” might have been derived from an Indo-European root of *ab*, *av*, *af*, or *op*); *elpe* (Norwegian); *iabloko* (Russian); *obolys* (Lithuanian)

***Mains angustifolia*.** From Sargent  
1905.

*craobb-ubhal-fhaidhain* (*craobb*, crab, *ubhal*, apple, *fhaidhain*, prophet's, Gaelic)

*fladh-abhal* (deer-apple, Gaelic)

*goirteag* (sour, Gaelic)

*maçã* [*maciera*, *maçanzeiro*] (from Latin *malinus*, Portuguese); *manzano* (Spanish)

*melo* (from Latin *mains*, Italian)

*na hollo intakkon* (*na hollo*, white man, *in*, his, *takkon*, peach, Choctaw)

*pommier* (from Latin *pomum*, the apple, French)

*sagara* (Basque)

*seb* [*seo*, *sev*] (Afghanistan!, Bengali, Hindi, from *seba* [*seva*], Sanskrit; akin to *sher*, Punjabi, *sib* [*séb*, *séff*], Persian, *súf*, Sindhi)

*tappuah* (Hebrew); *tuff ah* [*tiffâh*] (Arabic)

***Mains angustifolia*** (narrow-leaved) (= *Pyrus angustifolia*, not *Prunus angustifolia*, which see)

[southern, wild] crab [apple, crab-apple, crabapple] ("crab" is of uncertain origin, but maybe from Scandinavian *scrab*, *scrabbe*, the fruit, first used in English in A.D. 1420; if correct, then the combination with "apple," from 1712, is redundant)

*éco-em-pvkánv* [*eco em pvkanv*] (*éco*, deer, *em*, its, *pvkánv*, peach, Muskogee)

*ki'wile o'l ne'e* (*ki'wile o'l*, persimmon, *ne'e*, tree, Atakapa)

*shakulap* (Choctaw)

*she' hi* (apple tree, Osage)

*simmenachkee* (Shawnee, fide Edgar 1891)

*svkta* (Cherokee)

*takkolchobasi* (*takkola*, peach, *choba*, big, *-osi*, little, Alabama); *takkon masqfa* (*takkon*, peach, said to be the "old form" by Haag and Willis 2001, *masunfa*, an apple, Choctaw); *takolo maso' fa'* (Chickasaw)

Europeans were acquainted with the apple when they arrived in the New World. Indeed, their languages contained a number of words to describe the basic apple and its dozens of

cultivars and hybrids. Pallidus wrote in the 4th century A.D. that Rome grew 37 varieties (Bianchinni and Corbetta 1975); now between 7000 and 8000 cultivars are listed worldwide (Davidson 1999).

The latest studies suggest that the apple, historically called *Malus domestica*, *M. pumilus*, or *Pyrus malus*, may actually be a complex hybrid (Phipps et al. 1990, Manganaris Alston 1992, Mabberley 1997, Zhou and Li 2000, Robinson et al. 2001, Harris et al. 2002). The European “crab,” often called *M. sylvaticus*, appears to have escaped from cultivated plants; it is not their ancestor. The first records of Old World apples being imported to North America was in 1639 when the seeds were listed in an inventory of items taken to the Massachusetts Company (Hedrick 1919). John Josselyn was treated to “pippins” in 1639 grown on Governor’s Island in Boston Harbor, which was supposed to be the only place the trees were then grown in the New World (Hedrick 1919). “Pippins” has an obscure etymology (from Old French *pipin*), but it is a name applied to varieties of apples grown from seed since about A.D. 1430.

In the New World distinct kinds of apples were found, but they all were small-fruited trees that matched the European concept of the wild apple called a “crab.” Several of these grow in North America; Kartesz (1994) listed 11 species and 5 named hybrids. Perhaps the first wild crab apple was recorded by Giovanni da Verazzano along coastal New England in 1524, probably *M. coronaria* (Hedrick 1919). In early records, there may also have been confusion between *M. coronaria* and *M. angustifolia* because Hedrick (1919) still was not convinced that they were distinct. Other American apples probably have been recorded under the name “medlar.” For example, the journal of Lieutenant Diego Pena (1949) spoke of medlars among the Chickasaws in 1716.

The Cherokee ate the sun-dried fruits of both species in their part of the Carolina mountains (Moerman 1998). It seems likely that indigenous people mixed crab apples with their cornmeal cakes as they did other fruits.

Porcher (1863) wrote about what he called *M. coronaria*, although that species is rare in the geographic area he covered, saying: “It is not employed medicinally. The fruit is very acid to the taste, and is often made into preserves. The bark, with that of the white hickory, gives a yellow dye. Alum must be used as a mordant. The yarn should first be boiled with soap and water, then wrung out, and boiled in the preparation.” Fruits are used in jellies, pickles, preserves, and cider; they contain abundant pectin (Fernald et al. 1958, Uphof 1968).

The Creeks used a crab apple, probably *M. angustifolia*, in an attempt to cure rabies (1928a). The other species have been applied to an array of maladies (Moerman 1998). Seeds and leaves, especially when wilted, are toxic. These are among the members of the Rosaceae containing the cyanogenic glycoside amygdalin, which releases prussic acid (hydrocyanic acid) upon hydrolysis (Hardin and Arena 1974). However, fruits are edible if the seeds are discarded.

Wood is hard, close grained, and light brown tinged with red. It has been used for tool handles and levers (Sargent 1905). In spite of widespread use, Harrar and Harrar (1946) called *M. angustifolia* a “weed tree.”

Martin and Mauldin (2000) show that the name of the persimmon (*svtv*) was applied to the Old World apple when it arrived and eventually supplanted that native fruit. Eventually, *svtv* came to mean the apple and the native persimmon became the Seminole apple (*svtv semvnole*).

Similarly, the Alabama and Choctaw apply words that now mean “peach” (Sylestine et al. 1993, Haag and Willis 2001). Since the peach was introduced from the Old World, they have surely taken an old word and applied it to these new fruits. Maybe they have used the old word for the native plum, and reapplied it (see *Prunus*).

### *Manfreda*

(Named for an ancient Italian writer; British naturalist Richard A. Salisbury, 1761–1829, dedicated the patronym in 1866 to “*MANFREDUS de Monte Imperiali, scriptor antiquus de Simplicibus*”)

***Manfreda virginiana*.** From Britton and Brown 1896.

***Manfreda virginiana*** (of Virginia) (= *Agave virginica*, *Polianthes virginiana*)  
false aloe

*pa:ssa* (Creek); *pasí* (Mikasuki) (these names are usually given to *Eryngium*, which see)

rattlesnake master (alluding to the old use to treat snakebite)

Virginia agave (a book name)

The belief was widespread in the Americas that certain plants could be used to counteract the poison of venomous snakes. That concept dominated from New England and nearby Canada at least as far south as Mexico (Santamaria 1959, Vogel 1970). Until recently, this was all considered nonsense. Now a study by Castro et al. (1999) has experimental evidence that plant chemicals partially neutralize the hemorrhagic effect of snake venom. Castro et al. (1999) wrote: “Chemical analysis of these extracts identified catequines, flavones, anthocyanines and condensated tannins, which may be responsible for the inhibitory effect observed, probably owing to the chelation of the zinc required for the catalytic activity of venom’s hemorrhagic metalloproteinases.” No one is ready to espouse use of plant extracts alone to treat snakebite, but perhaps this is another example of our predecessors knowing more than we do.

Linnaeus ([1753] 1957) was not alone in having a less-than-clear concept of the genus *Agave*. He described *A. virginica* based on a specimen sent by John Clayton in the 1730s. In the same book, he described the genus *Polianthes*. Subsequently, *Agave virginica* has been placed in both *Manfreda* and *Polianthes*. Wunderlin and Hansen (2002) now include the species in *Manfreda*. Molecular genetic and morphological data suggest that *Manfreda* and *Polianthes* are closely related (Cronquist 1981, Bogler and Simpson 1995, 1996).

Gentry (1972, 1982) considered these plants members of the distinct genus *Manfreda*, and many have subsequently agreed (Verhoek 1975, 1977, 1978, Bogler and Simpson 1995, 1996). As a separate genus, *Manfreda* comprises 22 species in the southeastern United States and Mexico (Mabberley 1997).

Campbell (1951) and Sturtevant (1955) found records that Creeks in Florida in the early 1800s used both *Manfreda* and *Eryngium* to treat snakebite. The Creeks even called them by the same name. In both reports a decoction of the roots was used internally or externally to treat the bite. Campbell (1951) also noted that the "root of this plant boiled in sweet milk and taken freely, or chewed and swallowed is a certain cure for the bite of a rattlesnake." That was surely a late variation after they adopted Old World cattle.

The Catawba and Cherokee also considered *M. virginiana* potent medicine. The Catawba applied the plant in the same way that the Creeks did for snakebite. They also drank an infusion of the roots to relieve dropsy and used it as soap (Taylor 1940). The Cherokee chewed the root to expel intestinal worms, to stop diarrhea, and for the liver (Hamel and Chiltoskey 1975). They considered it "strong medicine."

Porcher (1863) noted that the plants were "[c]alled by Negroes rattlesnake's master," and considered a "domestic remedy for flatulent colic; used in Charleston district for the bite of the rattlesnake." Neither Millsbaugh (1892) nor Vogel (1970) mentions the species. Hocking (1997) recorded, "Roots bitter, used as carminative in colic, antispasmodic, stomachic."

Foster and Duke (1990) suggested that the plants might be a source of steroid synthesis, but warned that they may produce a strongly irritating latex. That comment is supported by the information that these plants and their Mexican relatives, like *Agave*, contain saponins. In Mexico, the plants are called *amole* (soap) or *huaco*.

The common name *huaco* or *guaco* complicates the story. Originally, *guaco* was a Taino name given to the genus *Mikania* in Cuba (Liogier 1962, Coll y Toste 1972). However, the word was taken to mainland Mexico, where it was applied to an array of plants, including the genera *Aristolochia*, *Mikania*, and even *Manfreda* (Standley 1920–1926, Santamaria 1959, Liogier 1962, Verhoek 1978).

Santamaria (1959) quoted from Élisée Reclus who wrote about *guaco* in Mexico in 1903. Reclus wrote: "*Mordidio tres veces por serpientes, nunca experimento ningun mal, porque desde su llegada al pais tuvo el cuidado de inocularse el guaco (planta bien conocido, cuyo jugo inoculado anticipadamente preserva con to do seguridad de la muerte, a los que son mordidos por serpientes venenosas)*" [Bitten three times by serpents, he never had a problem, because after his arrival in the country he took the precaution to inoculate himself with the *guaco* (a plant well known, whose sap taken in anticipation preserves completely from death, all of those that are bitten by venomous snakes)].

With time, the story grew more complex, and the name changed to *huaco*. Now *huaco* or *guaco* is translated “cow bird” but applied to two kinds of birds. One of them is also called *chicura*, *chileancho*, and *cuapaxtle* (*kwa:*, head, and *pa:xtli*, moss, Náhuatl), and is presumably the genus *Molothrus*, although which species is problematical. The other is the laughing falcon (*Herpetotheres cachinnans*). Legend has it that this bird was able to cure itself after a snakebite, and that gave rise to use of *Manfreda* to cure people (Verhoek 1978).

### *Manilkara*: Wild Dilly

(Michel Adanson created the genus in 1763 from *manil-kara*, a Malayalam vernacular name cited by H.A. van Rheede in 1683 from the Malabar Coast of western India)

My first introduction to the genus *Manilkara* came in 1969 when I lived at the mouth of the Amazon River in Belem, Brazil. One of the indigenous *mateiros* (woodsmen) with whom I worked in the forest studying vines brought me a fruit about the size of a tennis ball. The outside of the berry was rough, brown, and scaly, and it bled white milky latex from the stem where it had been attached to the tree. He told me it was a *sapotí*. Although I had never seen the fruit or the plants, I recognized the name as a Portuguese version of English “sapote” (*M. zapota*). At the time, I had no idea that both words and plants had been borrowed from the Aztecs of Mexico.

Because the fruit was unripe and bled white sap, I was not anxious to sample it. My friend, however, assured me that it would ripen and be “*muíto sabroso*” (very delicious). The fruit was set aside and temporarily forgotten.

*Manilkara jaimiqui*. a. Flowering branch, b to f. Flower: b. Early (female) stage; c. Side view; d. From above; e. Longitudinally dissected; f.

Corolla open out, one lobe and its  
 stamen folded forward to show scales,  
 g. Floral diagram, h. Branch with fruit.  
*Drawn by Priscilla Fawcett. From*  
 Correll and Correll 1982.

A few days later I rediscovered the fruit. It had shrunken somewhat and become wrinkled. Instead of bleeding white when it was broken, it showed a brown interior and had a wonderful smell. To me the taste was more like brown sugar than anything else.

When I moved to Florida in 1970, I was reintroduced to *M. zapota*, although this time the locals called tree and fruits “sapodilla” or “dilly.” In the interim, I had learned more about the tree, partly from my friend Paulo Cavalcante (Cavalcante 1974, 1976, 1979).

These trees, originally from southern Mexico and Central America, were important to the indigenous people of the region long before the Spanish arrived. Trees not only provided edible fruits, but also medicines from the leaves, a rubbery sap the Spanish learned to call *chicle*, and hard, heavy, strong, and durable dark red wood. The Aztec name *tzapotl* for these trees was altered to *zapote* in Spanish, and later to “sapote” in English. *Manilkara zapota* was sometimes called *sapotilla* (little zapote) by the Spanish in an incorrect translation of one of the Aztec names. In Náhuatl, these trees were either *xicozapotl* (*xicotli*, large bee, *tzapotl*, sapote) or *chictzapotl* (*chicle* sapote) (Simeon 1981). That sounded like “*chico zapote*” (little sapote) to the Spanish, and became *sapodilla*. People everywhere have a tendency to abbreviate words, and *sapodilla* became “dilly” in several English-speaking places.

Not long after arriving in Florida, I found wild sapodillas in the Keys that were not exactly like the cultivated plants I knew from the mainland or Brazil. It did not take long to determine that this plant was a wild relative of the cultivated species, known locally as “wild dilly.” At the time, the name in use was *Manilkara bahamensis* (Long and Lakela 1971), although John K. Small (1933) had called them *Mimusops emarginata*. Now the Florida and Bahama trees are *Manilkara jaimiqui* subspecies *emarginata*.

These Florida trees belong to *Manilkara*, a tropical genus of 65 species found in the Americas, Asia, the Pacific, Africa, and Madagascar (Mabberley 1997). All of the 20 species in the American tropics produce rubbery latex, but *M. zapota* was historically the most important to indigenous people, and has become commercially important worldwide. The first choice for use among the Aztecs and Mayas, as now, was for chewing gum. That may seem incomprehensible, but chewing is an ancient need of our species.

Different people chewed different materials. Northern Europeans chewed spruce gum, among other things, into the 1700s. The Spanish, however, learned much earlier of a better choice. That material became known as *chicle* (*tzictli* or *chictli*, Náhuatl). Bernardino de Sahagun, writing between 1519 and 1540, was perhaps the first to record use of the material. He wrote, “The people chew [*chicle*] because of the popping it caused on being mashed by the teeth” (Simeon 1981). Americans are addicted, as were the Aztecs. In the late 1980s we bought chewing gum at the rate of “ten million pounds a year” (Panati 1987).

The Aztecs thought so much of the tree producing chicle that they named localities after it, as in *Tzapotlan* (*tzapotl*, sapote trees, *tlán*, place of). They also had a *Tzapotlan teohuatzin*, which was a priest in charge of making arrangements for the deity *Tzapotlatenan* (*tzapotlan*+*nantli*, mother), the deity of the hot baths and of medicines. She was thought to have discovered *oxitl* (resin from pines), which was used to treat a variety of illnesses.

This favorite chew of the Aztecs and other people in Mexico did not immediately become popular with Europeans. It was 1707 before the words “chewingballs” appeared, and they referred to spruce and tobacco. Children chewed spruce; men preferred tobacco.

In 1845, Antonio López de Santa Anna, defeated Mexican commander who led the destruction of the “Alamo” in Texas in the 1830s, settled on Staten Island, New York. Thomas Adams, a local New York inventor, learned of the chewable sap from Santa Anna, and imported a quantity gathered by *cichleros* in Mexico and Mesoamerica (Simpson and ConnerOgorzaly 1995). Later, he sold the sweetened *chicle* formed into balls and marketed them as a substitute for the paraffin then being sold as a “chew” for youngsters. The first *chicle* balls were sold in 1870. Although the expression “chewing gum” was in common use in local speech, it took Mark Twain to give literature “chawing-gum” in 1871 (Panati 1987). “Chicle” did not appear in English until 1889.

Among the formerly isolated people of the Caribbean islands, *M. jaimiqui* had assumed an importance similar to *M. zapota* on the mainland. *Jaimiqui*, the species name of this tree, is taken from the Taino language, and it is still the name in Cuba, Hispaniola, and Puerto Rico. People in Hispaniola have shortened *jaimiqui* and say *jaiquí*, a name they also apply to *Sideroxylon salicifolium* (see *Sideroxylon*: Mastic and Busic). Although *acaná* [*jdcaná*, *hácana*] (Taino, Puerto Rico) has been listed as a common name of *M. jaimiqui*, it is usually applied to *M. bidentata*. However, since indigenous people used both trees in similar manners, those names may also be “correctly” applied to *M. jaimiqui*.

Other people call *M. jaimiqui* by other names. *Acubá*, usually now rendered *ausuba*, is another Taino name also applied to *M. zapota* in Puerto Rico. Additional comparisons include *zapote de cost a* (coastal sapote, Puerto Rico) and *mameyuelo* (little *mamey*, Puerto Rico). The Taino name *mamey*, which appeared in English in 1572 and became “mamee,” was an alternative name for both *M. zapota* and *M. jaimiqui*. However, it usually applied then and now to another member of the Sapotaceae, *Mammea americana*.

Europeans in the Dominican Republic began calling these trees *nisperillo* (little *níspero*) and *nisperillo de hojasfinas* (little *níspero* with fine leaves). Those are diminutive forms of *níspero*, which is *Manilkara zapota*. Hard as it is to believe, *níspero* is based on the Latin *mespilus*, which was the classical name for what in English is the medlar (*Mespilus germanica*, Rosaceae). The Spanish and English names have the same Latin root word, and they were originally applied to an Old World plant that largely was supplanted in tropical American diets by various *Manilkara* species.

Second to chewing the sap, eating the fruits was probably the most widespread use of wild dilly. If enough trees were available, they were also used for their wood. Trees still are used for timber in Hispaniola and Puerto Rico, and the wood is prized for its wine-red color. *Manilkara jaimiqui* wood is hard, strong, and used for roof supports, braces, and naval construction (Liogier 1974).

Like its more famous relative *M. zapota*, wild dilly is medicinal (Eldridge 1975). In the Bahamas, fruits are eaten in moderation because they make the bowels “hard to move” (Ayensu 1981). That difficulty with constipation after eating too much fruit is thought to be because of the latex (Morton 1981). Tea from leaves is used at least in the Bahamas to relieve flu and fever (Ayensu 1981, Morton 1981). In Cuba, the plants are famous as an astringent and antiseptic (Roig 1945).

People in Trinidad and Tobago still use the seeds of *M. zapota* and the related *Pouteria sapota* and *Mammea americana* to control ectoparasites on their dogs (Lans et al. 2000). At least in *Manilkara*, they work for that purpose because seeds contain poisonous saponins. According to a study by Singh et al. (1984), the potency is high, with the lethal dose  $LD_{50}=30$  to 50mg/kg.

Wild dilly is rare in Florida and apparently elsewhere in its range (Liogier 1974, Liogier and Martorell 1982). In Florida, the species is considered threatened by the State of Florida (Administrative Code Rule Chapter 5B-40, Coile 2000). This resource, so prized by former natives of the New World, is now being bulldozed as coastal forests are destroyed to build expensive housing for the wealthy. Mostly, these native trees are being replaced in landscaping with imports from other continents. The values of some people changed as we became a mechanized society divorced from and largely ignorant of the living world around us. Even worse, people living in those homes will never know what they have denied future generations.

### *Marshallia*

(Dedicated to American Moses Marshall, 1758–1813, nephew of dendrologist Humphrey Marshall, 1722–1801, and cousin of John Bartram)

*Marshallia obovata* (leaves are obovate, that is, like the inverse of an egg or spoon-shaped)  
[spoon-shaped] Barbara’s buttons

Once in the early 1970s I found a *Marshallia* growing in a pine flatwoods in Jonathan Dickinson State Park in Martin County. Each year for the next two decades I returned to the site. I was unable to relocate the plants although Wunderlin (1998) shows *M. tenuifolia* growing south into Palm Beach County. I cannot say how rare these Barbara’s buttons are farther north, but they are certainly uncommon in the southern end of their range.

That was the only time I ever saw the genus, and that is not too surprising because two of the three species in Florida are on the state endangered list (Coile 2000). *Marshallia*, a genus endemic to North America, contains seven species (Channel 1957). The group was named in 1791. At the time Henry [formerly Gotthilf H.E.] Muhlenberg (1753–1815) was a Lutheran minister and pioneer botanist in Pennsylvania. He learned that his countryman Johann C.D.von Schreber, a professor in Erlangen, Germany, was revising the eighth edition of Linnaeus’s *Genera Plantarum*. Muhlenberg requested that Schreber name this new genus of Asteraceae for Moses Marshall.

*Marshallia obovata* is endangered in Florida where it grows only in Jackson County (Coile 2000). Elsewhere the species is known from Virginia to Georgia, and in Alabama (Coile 2000). Fernald (1950) reported var. *platyphylla* also from Missouri, but Steyermark (1963) did not include the species. Regardless, Wunderlin (1998) included the variety within the species.

The species was named by Thomas Walter in 1788, but it was not until 1901 that it was placed in *Marshallia*. Apparently, the plants are not that common anywhere in their range, and little seems to have been recorded about them. Among indigenous people, we know only that the Catawba used this herb as a remedy for some disease (Moerman 1998).

### *Maytenus*

(From the Araucan name *maiten*, *mayten*, or *mayton*, used in Chile for *M. boaria*)

#### *Maytenus phyllanthoides*. a.

Flowering branch, b. Leaf axil with three serial dormant buds. c. Leaf axil with lower bud developed as a branch, d. Flower, from above, e. Flower, longitudinally dissected, f. Floral diagram, g. Branch with fruit, h. Unripe fruit, i. Dehiscent fruit, j. Fruit longitudinally dissected. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

***Maytenus phyllanthoides*** (resembling *Phyllanthus*, a genus of Euphorbiaceae, because of the fruits below the leaves in both)

Florida mayten (Florida)

gutta-percha mayten (Florida)

leather-leaf (Texas)

*mangle aguabola* (water trunk mangrove, Mexico)

*mangle dulce* (sweet mangrove, Texas)

*verdolaga* (a name usually given to *Portulaca oleracea*, Cuba)

*Maytenus phyllanthoides* was named by George Bentham in 1844. The genus contains about 200 species growing in the tropics and warm parts of the world (Mabberley 1997). Several species throughout the range of the genus furnish products used by humans.

Leaves of *M. phyllanthoides* produce a gutta percha, which is used as a remedy for toothache and scurvy in Mexico (Martinez 1969, Hocking 1997). The wood is used as fuel.

### ***Medeola***

(Named for the Greek princess, priestess, and witch, Greek *Medeia* or Latin *Medea*; daughter of the Colchian king Aeetes, Jason married her in exchange for her help, and brought her home with him to Hellas; so named for its reported medicinal virtues)

***Medeola virginiana*.** From Britton and Brown 1896.

***Medeola virginiana*** (of Virginia)

*concombre sauvage* (wild cucumber, apparently both French *concombre* and English cucumber were derived in the 1300s from Latin *cucumis*, Quebec)

[Indian] cucumber-root; *Gurke indische* (Indian cucumber, German)

*jarnotte* (Quebec)

Virginian medeola (a book name)

When Linnaeus adopted the genus *Medeola* in 1753, he accepted the name proposed by Jan F. Gronovius in his *Flora Virginica* published between 1739 and 1743. Leonard Plukenet had also described these New World plants in 1696, but he incorrectly put them in *Lilium*. The monotypic genus is endemic to eastern North America, and it is probably related to *Clintonia*, which has four species in North America and one in eastern Asia (Mabberley 1997, Utech 2002).

Manasseh Cutler is considered the first to record that the root was eaten by indigenous people in New England in 1785 (Fernald et al. 1958). Presumably, the people referred to by Cutler were the Iroquois (Moerman 1998), but it may have been several tribes because Yanovsky (1936) says in the “northeastern states.” By 1814, Frederick T. Pursh in his *Flora Americae Septentrionalis* reconfirmed Cutler’s observation (Hedrick 1919). Asa Gray said in 1868, apparently from personal experience, that the tuberous, white rootstock has a taste like the cucumber (Hedrick 1919).

Most references suggest that the first record of the plant’s medicinal use among indigenous people came from the time of Barton. For example, Porcher (1863) wrote, “Dr. [B.S.] Barton [in 1810] thought it useful in dropsies. It enjoys some reputation as a hydragogue... it is esteemed a very active diuretic.” However, the generic name applied by Gronovius and Linnaeus was apparently already based on knowledge that *Medeola* were used as remedies. Gray (1875) wrote, “Named after the sorceress *Medea*, from the wholly imaginary notion that it possesses great medicinal virtues.” Fernald (1950), always a careful student of etymologies, similarly wrote, “Named after the sorceress *Medea*, for its imagined great medicinal virtues.” Both her name and the genus were derived from Latin *medela*, or *medella*, meaning healing or remedy (Quattrocchi 1999).

However capricious Linnaeus may have been about using names with double or even triple meanings, he did not invent or use them without some basis. It is clear that the Iroquois used *Medeola* to cure maladies (Moerman 1998). That information would have been conveyed to Linnaeus, especially since it is a Peter Kalm specimen that typifies *M. virginiana* (Linnaeus herbarium No. 468.1, LINN). More certain is that Linnaeus continued use of Gronovius’s name *Medeola*. Gronovius had written “An Ipecacuanah” on the sheet that John Clayton collected in 1734, thus comparing it to the famous South American emetic *Cephaelis ipecacuanha*, Rubiaceae. Clearly, both Gronovius and Linnaeus had information about medical application, probably in both Virginia and New England.

Moerman (1998) indicated that the Iroquois used an infusion of crushed dried *Medeola* berries to treat infants with convulsions and incorporated the plant into their “Little Water Medicine.” Fernald et al. (1959) wrote, “In view of the attractive appearance of the root, it is surprising that it is not mentioned by other students of Indian foods.” Although they were talking about foods, the statement is equally applicable to medicine.

### *Melanthera*

(From Greek *melas*, black, and *anthos*, anther, noting how the anthers contrast with the white corollas)

***Melanthera nivea*.** Drawn by  
*P.N.Honychurch.*

***Melanthera nivea*** (refers to the snow-white corollas) (= *M. aspera*)  
*aprokoka* (Peru?)

*bega* (Belize)

*botón de plata [de playa]* (silver bud [beach bud], Cuba); *botoncillo* (little bud, Central America); *botón blanco* (white bud, Central America); *bouton blanc* (white bud, Guadeloupe, Martinique)

*cabeza negra* (black head, Central America)

*caraquillo [caraquito] blanco* (white little *caraqui*, Puerto Rico, Venezuela)

*cat tongue* (Bahamas)

*la chinoise* (the Chinese, Guadeloupe, Martinique)

*clavel blanco* (white carnation, Dominican Republic); *clavellina de monte* (little wild carnation)

*cosagané* (Central America)

*ehitiilelem* (like *kelem [Bidens alba]*, Huastec, San Luis Potosí)

*flor de la vida* (flower of life, Central America)

*hierba de caballo* (horse herb, Central America)

*hotz* (to spit, Maya, Belize)

*julio* (July, the month it flowers?)

*margerite bord-de-mer* (border of the sea margerite; margerite given to *Leucanthemum*, formerly *Chrysanthemum*, in Europe, Guadeloupe, Martinique); *marguerite blanche* (white marguerite, Guadeloupe, Martinique)

*orozúz* (recorded by Morton 1981, but given for *Conyza canadense* by Liogier and Martorell 1982)

*ouache-ouache* (padding?, Hispaniola)

*paira* (bow for shooting arrows in Taino, but surely from some other source, Costa Rica)

*salaillo* (Puerto Rico)  
*sirvulaca* (Peru?)  
 Spanish needle (Belize)  
 square-stem [squarestem] (Florida)  
*totalquelite* (all-greens, Nicaragua)  
*tup-lan-xix* (*tup*, extinguish fire, *Ian*, immerse, *xix*, excess, Maya, Belize; see also *Ageratum*)  
*yerba de cabra* (goat weed, Puerto Rico)

Linnaeus ([1753] 1957) named 11 species of *Bidens*. One of them, *B. nivea*, we now know as *Melanthera nivea*. It was not until 1792 that Julius Philip Benjamin von Rohr (1737–1793) created *Melanthera*, and not until 1903 that J.K.Small put the Linnaean species in it. Today there are at least 40 species, excluding those in the Far East (Mabberley 1997).

People in the Caicos Islands use a decoction, paste, or powder to cure sores (Morton 1981). Nahuatl speakers in Veracruz still treat headache with it (Vásquez and Jácome 1997). In Panama, people use the plant as forage for cattle (Standley 1928). People in northwestern Venezuela rub the plant on their faces before hunting, believing it will improve their marksmanship (Morton 1981).

Several other species of *Melanthera* are used (Parks 1973, Hocking 1997), and there appear to be several bioactive compounds involved (Rivera et al. 1980, Hanson et al. 1994, Penders and Delaude 1994).

### *Melochia*

(Linnaeus named this from Greek *meli*, honey, *echo*, to hold; also possibly from *meli* and *locheia*, childbirth, ancient name for a plant supposed to ease parturition; Arabic *melochich*, is the name for a *Corchorus* in the same family)

***Melochia tomentosa*** (pubescent)  
*basora com* (weed broom); broom-weed [-wood] (Puerto Rico, Virgin Islands)  
*bretónica* (little tail, Puerto Rico, Venezuela); *bretónica afelpada* (hairy little tail, Puerto Rico); *bretónica morada* (purple little tail, Venezuela)  
*cariquito [morado]* ([purple] usually applied to *Lantana*, Venezuela)  
*deshinchadera* (swelling reliever)  
*escoba roja* (red broom); *escobilla* (little broom, Dominican Republic)  
*malva* (mallow); *malvavisco* (usually applied to *Malvaviscus*, Puerto Rico)  
 raichie (Jamaica)  
 red rope (Bahamas)  
 tea bush (Jamaica)  
*toton*  
*varita de San José* (St. Joseph's little broom, Nicaragua)

velvet-leaf (Cayman Islands)

*zac-chichibe* (*sac*, white, *chichibe*, something in the path that sticks, the name of *Stylosanthes hamata*, so “white” is added to distinguish *Melochia*, Mayan)

Linnaeus ([1753] 1957) named *Melochia*, and described *M. tomentosa* from Jamaica in 1759. Since then the genus has grown to 54 species, which are especially common in the American tropics (Mabberley 1997).

None of the literature mentions it, but the most widespread use of *Melochia* is as a broom—as noted in many of the common names. In addition, there are a number of medical applications. This is not surprising because of the novel chemicals in the genus (Tschesche and Reutel 1968, Palmer 1975, Kapadia et al. 1975, Breuer et al. 1982).

Bahamians boil roots into a decoction used to relieve back pain (Ayensu 1981, Morton 1981). In Curaçao a decoction is gargled for sore throat and used as a cold remedy in Jamaica (Ayensu 1981, Morton 1981). The decoction is also drunk for stomachache and recommended to stop diarrhea in Aruba. A decoction of powdered roots is used for an emmenagogue (Morton 1981). In Venezuela the plant is either taken internally or used in baths to reduce swelling of legs and feet; it is also a remedy for eye problems (Pittier 1926). Like *M. pyramidata* in Cuba (Roig 1945), *M. tomentosa* is used as an emollient in much of Latin America (Morton 1981, Vásquez and Jácome 1997).

### *Melothria*

(Greek *melothron*, a “melon” or apple, an ancient name used by Theophrastus, 372–287 B.C., and Dioscorides, fl. A.D. 40–80, for some plant, perhaps *Bryonia*; Latin *melothron* or *melotrum* applied by Pliny, A.D. 23–79, to “*Vitis alba*”)

***Melothria pendula***. a. Section of fruiting stem (above) and tip showing tendril (below), b. Inflorescence of staminate flowers, c. Staminate flower, longitudinally dissected, d. Floral diagram of staminate flower, e. Branch with pistillate flower, f. Advanced pistillate flower, side view, g. Advanced pistillate flower, longitudinally dissected, h. Floral diagram of pistillate flower, i. Unusual leaf form. *Drawn by Priscilla Fawcett*. From Correll and Correll 1982.

***Melothria pendula*** (hanging down, meaning the fruits)  
*bejuco sin madre* (vine without a mother, Dominican Republic)  
*cereja purga* (purging cherry, Brazil)  
 creeping cucumber (Florida, Bahamas); *pepinillo* [*cimarrón*] ([wild] little cucumber, Cuba, Puerto Rico); *pepinito* (little cucumber, Puerto Rico); *pepino cimarron* (wild little cucumber, Cuba); *snekikomkomro* (snake cucumber, Sranan, Suriname)  
*I'herbe à congo* (snake herb, Houma, Louisiana; see also *Ipomoea sagittata*)  
*melón de ratón* (mouse's melon, Belize)  
*teta de perra* (dog's tit, Cuba)

Sir Hans Sloane and Leonard Plukenet both recorded these vines from the Caribbean in 1696. Linnaeus had seen them cultivated at both the *Hortus Cliffortianus* and *Hortus Upsaliensis* before he named them *Melothria pendula* in 1753. Although both Sloane and Plukenet had called them a *Cucumis*, Linnaeus appropriated for them an old term for a melon. There are now ten species, all native to the New World; several have edible fruits and are used locally in medicines (Mabberley 1997).

Fruits are eaten in the Bahamas, while some consider them poisonous (Diggs et al. 1999). According to Roig (1945), four seeds are enough to purge a horse. In spite of that potency, they are used when purges are needed in Cuba. In Belize, the plants are used as medicine, food, and poison (Balick et al. 2000).

Many years ago I mentioned to a Bahamian woman that they were poisonous, and she replied that she had eaten them raw and pickled for years. Fruits are also eaten in Hispaniola (Liogier 1974). The Houma used pulverized leaves and gunpowder to treat a water moccasin bite (Speck 1941).

*Menispermum*

(From Greek *mene*, moon, *sperma*, seed; referring to the shape of the seed)

*Menispermum canadense*. From Britton and Brown 1897.

*Menispermum canadensis* (from Canada)

maple vine [vine-maple] (some think the leaves look like those of the maple, *Acer*, which see)

*ménisperme du Canada* (Canadian moonseed, Quebec)

moon-creeper

[Canada, Canadian, common, Virginian] moonseed (according to the OED 1971, the common name came from the Latin and was first used by Philip Miller in his *Gardeners Dictionary* of 1739; the modifiers “Canadian” and “Virginian” were added by 1822); *Mondsame* (moonseed, German)

*raisin de couleuvre* (snake grape, Quebec)

[American, Texas, yellow] sarsparilla (from Spanish *zarza*, briar, *parilla*, small grape vine; the name “saraparilla” has been applied to a number of plants, Indiana, Ohio; apparently, “safariilla” is a corruption of sarsparilla, Kentucky)

yellow parilla (the word “parilla” is apparently a shortened form of “sarsparilla”; although *parilla* is Spanish, a diminutive form of *parra*, grape vine, that seems to be incidental)

Linnaeus ([1753] 1957) named these plants based on literature and personal knowledge of cultivated specimens in Europe. He had studied living plants at the *Hortus Cliffortianus* and at the *Hortus Upsaliensis*. In publications on both places he followed Jan Gronovius’s *Flora Virginica* from 1739–1743 and called the plants *Menispermum foliis peltatis subrotundis angulatis* (moon-seed with peltate, almost round and angular leaves). Linnaeus adopted the first two words of Frenchman Joseph Pitton de Tournefort’s (1656–1708) polynomial from 1705 when he named the vines

*Menispermum canadense*. Happily, he was not swayed by Leonard Plukenet's name of 1696, *Hedera monophylos virginiana, convolvuli foliis* (Virginia ivy with one leaf, leaves like *Convolvulus*).

We now know two (maybe four) species in *Menispermum*, and these are shared between eastern North America and eastern Asia (Mabberley 1997). The Japanese *M. daurica* is the ecological analogue if not the sister to *M. canadense* (Ohwi 1965). That Japanese plant has also been used in the same ways as the American (Foster and Duke 1990).

Only three tribes are known to have used *M. canadense*, but probably more did. The Cherokee took a remedy of the vines for weak stomach, diarrhea, as a laxative, for venereal disease, and to strengthen "weakly females" (Hamel and Chiltoskey 1975). The Delaware put the plants in a salve used on chronic sores (Moerman 1998). The Ojibwa used the vines for an undisclosed medicine (Vogel 1970). Rafinesque said indigenous people used the root in scrofulosis, but did not say which tribes (Millspaugh 1892).

Porcher (1863) wrote: "[Steven] Ell[iott] never saw it, but thinks that it grows in the mountains. Dr. [Asa] Gray determined a specimen sent from St. John's, Charleston district, by H.W. Ravenel, Esq., to be this.... It is said to be much used in Virginia by physicians; and in domestic practice, as a substitute for sarsaparilla, in scrofulous and cutaneous affections... the roots are tonic, alterative, and diuretic.... It is also employed by the vegetable practitioners.... Said to be laxative and tonic, and used in debility and in giving tone to the stomach and nervous system."

Millspaugh (1892) recorded that early settlers found the root useful as a diuretic to relieve strangury in horses. He also noted that the root was used much like sarsaparilla, i.e., treating syphilitic, scrofulous, and rheumatic diatheses; as a laxative; as a tonic for use against general debility, atonic dyspepsia, and "kindred problems"; and as a remedy for pleural adhesions and inflammations of the alimentive mucous membranes.

As late as the 1980s, the remedy was used in Appalachian Kentucky to "cleanse the blood," where "one span of sasfriller root is boiled in a quart of water until one-half pint of liquid remains. One half pint of whiskey and a heaping tablespoon of sulfur are added to this. One spoonful is taken before each meal until it is all used up" (Bolyard in Coffey 1993). With that much whiskey each day, it would at least relax patients enough so that they might heal.

Moonseed was official in the U.S. Pharmacopoeia between 1882 and 1905, and in the New York edition from 1831 to 1842 (Vogel 1970). Duke et al. (2002) list the vine's qualities as alterative, cyanogenic, diaphoretic, diuretic, laxative, nervine, poisonous, stomachic, and tonic. They state that it has been used to treat cancer, constipation, debility, dermatosis, enterosis, fever, gastrosis, gout, scrofula, sores, syphilis, venereal disease, and water retention. They rate it in terms of safety along with a single cup of coffee, but refrain from commenting on its probable utility.

There are certainly bioactive compounds in *M. canadense*. Among the chemicals known are the isoquinoline alkaloids, including dauricine, a compound with curare-like action. The grapelike fruits contain isoquinoline alkaloids and have been fatal to children eating them (Lewis and Elvin-Lewis 1977, Turner and Szczawinski 1991).

***Metopium*: Poisonwood**

(Uncertain; the classical Greek name *metopion* is the gum of an African tree now unidentified; most sources translate *metopium* as forehead)

There are two native trees in southern Florida that cause dermatitis (or worse) in sensitive individuals. Probably the most famous is the manchineel (*Hippomane mancinella*); the other is the poisonwood (Bahamas, Florida). The manchineel is in the Euphorbiaceae, while the poisonwood is *Metopium toxiferum* in the Anacardiaceae. In other words, the poisonwood is related to poison ivy (*Toxicodendron radicans*), poison oak (*T. pubescens*), poison sumac

***Metopium toxiferum*. Drawn by  
P.N.Honychurch.**

(*T. vernix*), cashews (*Anacardium occidentale*), and pistachios (*Pistacia vera*). It is a family famous for causing human misery and delight.

Although I was familiar with both poison ivy and cashews when I arrived in Florida, the poisonwood was new to me. It took me some years to learn to distinguish it from gumbo limbo (*Bursera simaruba*), although now I find them so distinct that I wonder why I ever had trouble. I quickly learned the reputation of poisonwood and carefully avoided contact with it. That was not always true of my students. Repeatedly over the years, different individuals brought in leaves or branches of poisonwood either totally puzzled about the identification or thinking that they were gumbo limbo. Few of us actually ever got dermatitis from the specimens, although a couple who were gathering ecological data for me came down with rashes in unexpected places after working alone in the field.

My only direct experience with the rash came from a “free” trip with Donovan Correll during the creation of his *Flora of the Bahama Archipelago* (Correll and Correll 1982). We made a collecting trip to Andros, and I followed him and our local guide through *Metopium* and *Clusia* forests much of the day. That would not have been so bad except that they kept breaking poisonwood branches in front of me and leaving them to drip resin as I passed. It was not until we were in the small plane on our way back to Miami that I discovered a large blister growing on one finger. That “free” trip cost me two visits to the dermatologist’s office and two injections of cortisone. If I had only known of the Bahamian and Mexican remedies it might have saved me considerable expense and discomfort. In the Bahamas, they take leaves from the “maiden fern” (*Thelypteris kunthii*)

parch and powder them, and sprinkle the dust on dermatitis caused by poisonwood. Mexicans use the leaves of gumbo limbo to relieve the dermatitis, and there seems to be some chemical basis for that (Peraza-Sánchez and Pena-Rodriguez 1992).

Catesby (1731–1732) introduced Europeans to these plants when he wrote, “From the trunk of this Tree distils a liquid black as Ink, which the Inhabitants say is Poison.” He had found the plants on Providence, Eleuthera, and other islands of the Bahamas where I had my unpleasant contact with the sap and unwittingly verified the reports of the Bahamians who told him about the poison. Catesby called the plants *Toxicodendron foliis alatis fructu purpureo pyriformi sparso* (the poison wood with winged leaves and sparse purple pear-shaped fruits). That comment about the fruits is odd because they are yellow to orange.

The Catesby text and plate were the only source that Linnaeus had for the species when he named it in 1759. Perhaps that is why poisonwood was a puzzle to him. Linnaeus did not realize that the plants were related to those we now put in the Anacardiaceae. For some odd reason, Linnaeus called the trees *Amyris toxifera* in 1759, thereby putting them with *Amyris*, *Citrus*, and *Zanthoxylum* in the Rutaceae. Indeed, Linnaeus ignored that Patrick Browne had created a genus for these poisonous plants in 1756 when he published *Metopium* in *The Civil and Natural History of Jamaica* for what we now call *M. brownei*. Linnaeus instead called them *Rhus metopium*, and missed the connection with Florida’s *M. toxiferum*.

Browne’s name for the plants has puzzled people from the beginning. He applied to New World plants the classical Greek name *metopion* for the gum of an African tree now unidentified. Most sources translate *metopium* as “forehead,” but it is unknown exactly what Browne meant. I suspect that he, or someone he knew, had brushed against resin on the trees and developed a rash on the forehead. Since he would have been familiar with the classical Greek, he saw the connection with the old word and called the plants *Metopium*. Another interpretation is that the Latin means “poison carrying,” and that would also make sense (Nellis 1997).

The poisonwood in southeastern Florida also occurs in the Bahamas, Cuba, Hispaniola, Puerto Rico, and Anguilla. Within its range, it has several common names, most of which allude to its poisonous nature. Sometimes in Florida it is called the coral sumac, and in the Bahamas it is poisons tree. Oddly, it is Florida poisons tree in Puerto Rico although it is native to that island. Cubans usually call it *guao de costa* (coastal *guao*, Taino, Cuba). That reference is a comparison with the “true” *guao* (Puerto Rico), *Comodadia glabra* in the same family. Sometimes the *Metopium* also is called *guao* (Hispaniola).

There is almost complete overlap of common names in Hispaniola with *Hippomane*. There the *Metopium* is called various renditions of *manchenille* (little apple, Haiti) or *manzanillo* (little apple, Dominican Republic). Mostly, the trees are simply *manchenille* or *mancenillier* (little apple tree, Haiti). However, there are other names variously pronounced so that they actually have different meanings in French. These other names include *machanoise* (chewer, Haiti), *machandeuse* (chewer, Haiti), and *maximier* (maximizer, Haiti). Haitians also call the trees *bois mulâtre* (mulatto tree).

The first mention of this tree in Florida may have been by DeBrahm ([1775] 1971), who called it *papajos*, although his description of the plants reads like a mixture of satinleaf (*Chrysophyllum olivaeforme*) and something else (Austin 1980). The name

*papaya* is used for *Metopium* in Puerto Rico, but elsewhere it means papaya tree (*Carica papaya*, Caricaceae). DeBrahm's book contains many curious comments, confusions, and allusions to contacts with the Caribbean, where he may have heard the name. In Puerto Rico, the trees also are known as *almendrón* (big almond) and *cedro prieto* (black cedar).

Poisonwood contains alkylcatechols (urushiols), as do its relatives in *Toxicodendron* (Rivero-Cruz et al. 1997). Urushiol is a mixture of compounds, each with a catechol ring having a 15-carbon side chain with one or two double bonds. In the presence of oxygen in the skin, the urushiol is converted into a quinone that binds to proteins (Nellis 1997). Not surprisingly, those compounds are allelopathic to higher plants and inhibitory to fungi (Rivero-Cruz et al. 1997, Anaya et al. 1999). The toxin is stable and remains in the leaves and wood as long as they remain intact. In spite of that, people have used the wood for hundreds of years, although they are often irritated by the sawdust. Once finished, the wood is harmless, takes a fine polish, and is used for furniture and other items.

As incredible to those of us who are sensitive to those poisons in the Anacardiaceae find it, *Metopium* has been used medicinally. The resin is known as hog gum or doctor gum (Uphof 1968). It is emetic, purgative, diuretic, sudorific, and sedative (Roig 1945). The wood has been used to adulterate *Quassia amara* (Uphof 1968).

Several other authors simply say that the resin has "medicinal properties." Those who give details on use of the resin indicate that it has been used to treat erysipelas and inflammatory rheumatism. Poisonwood also has been used as an abortifacient; however, the "remedy" is notorious for also killing the mother (Ayensu 1981, Morton 1981). That result should not be a surprise considering that the "cure" contains 13 packets of Epsom salts, and 1 quart of chlorox bleach in addition to *Metopium* and *Maytenus buxifolia*. Another widespread usage is to "remove" an aching tooth. Apparently, dabbing the "milk" (resin) on the offending tooth kills the nerve to the point that it can be removed without problems. I shudder to think of the impact the urushiol would have on the sensitive mucous membranes.

There are only three or four species in *Metopium*. In addition to *M. toxiferum*, the other widespread Caribbean plants are *M. brownei*, known from Veracruz, Chiapas, Campeche, Yucatán, and Quintana Roo in Mexico, and south through Belize and Guatemala to the islands off Colombia. Within the Caribbean, the species grows in Cuba, Jamaica, Hispaniola, and the islands of Aruba, Bonaire, and Curaçao. The tree is oddly missing from Puerto Rico. *Metopium venosa* is endemic to Cuba, and *M. gentlei*, which Mabberley (1997) does not recognize, was described from Guatemala.

Of the related species, *M. brownei* has been used in all of the same ways as *M. toxiferum*. The wood of this species is especially esteemed, and it is prized for making furniture in spite of the hazardous sawdust. The Maya of Yucatán do not seem to completely share that opinion of the trees. They call the trees *boxcheché* (*box*, black, *che'*, tree, *chem*, canoe). They also call the trees *kabal chechem*, where *kabal* is a derogatory term meaning "low in stature." That's how I felt when I was contaminated with Bahamian poisonwood sap—low in morale and stature.

### *Mikania*

(Named for Bohemian Joseph Gottfried Mikan, 1743–1814, professor at Prague)

***Mikania scandens* (climbing)**

climbing hempweed [hemp vine] (Florida)

*guaco* (indigenous Taino name for the vines, Cuba); *guaco blanco* (white *guaco*, Colombia)

*halosvkatv entihv* [*a: ló: saká: ta intayhóci, halocsha kate entahe*] (moccasin's scaffold; *halosvkatv*, water moccasin, *entihv*, bed, Creek);

***wahote***

*entayhe* [*wahó: rintayhi, waaho(th)e entahe*] (water moccasin scaffold; *waaho(th)e*, water moccasin, *entahe*, bed, Mikasuki)

This was another of the species that Linnaeus included in his broad concept of *Eupatorium* in 1753. It was not until Willdenow studied them in 1800 that he created the genus *Mikania* for what Linnaeus called *E. scandens*. Since then, the genus has grown to about 430 species in the tropics of both hemispheres (Mabberley 1997). Several species are used as medicines.

Seminoles use the same name for *M. scandens*, *Aster caroliniensis*, *Ipomoea sagittata*, and *Ludwigia*. These vines are used to treat "Snake Sickness"

***Mikania scandens*.** a. Section of stem. b. Head of four flowers, c. Single flower, d. Flower with corolla removed showing anthers united into a tube. e.

Anthers spread out. *Drawn by Vivian Frazier*. From Correll and Correll 1972.

(Sturtevant 1955, Bennett 1997). A medicine to treat snake bite still is made from the stem and leaves of *M. scandens* mixed with other plants (Bennett 1997). This plant is used in Cuba for intestinal and stomach problems, including diarrhea (Roig 1945).

Cubans also treat intestinal ailments and rheumatism with the leaves of *M. cordifolia* (Roig 1945). In Brazil and the French West Indies, a decoction is used to treat snakebite. *Mikania guaco* is used as a febrifuge and snakebite remedy throughout the West Indies and Mesoamerica (Morton 1981).

### *Mitchella*

(Commemorating physician John Mitchell, 1711–1768, a correspondent of Linnaeus who resided in Virginia; he was elected a fellow of the Royal Society in 1748)

#### *Mitchella repens* (creeping)

[box, chicken, cow, deer, fox, Jesuit, one, snake, squaw, tea, turkey]-berry  
(Alabama, Massachusetts, Michigan, New York)

*Mitchella repens*. From Britton and Brown 1898.

[creeping] checker-berry [creeping checkerberry] (the OED says these plants came to be called “checker-berry” by 1849 because of confusion with *Gaultheria procumbens*; perhaps the name refers to the fruit, which Thomas More said in 1723 has “a small red berry white in the middle, but, while not fully ripe, white and red prettily streaked like a Pomegranate,” Massachusetts)

eye-bright (in Europe the name is usually given to *Euphrasia officinalis*; reapplied to a variety of plants in the Americas, Massachusetts)

*fi: tó imilpá* (*fi: tó*, turkey, *im*, its, *ilpá*, food, Koasati)

hive-vine (New York) mountain-tea (New York)

*pain de perdrix* (partridge bread, the spelling *perdriz* is archaic; modern French uses *perdrix*; from the Latin *perdix*, Quebec); partridge-berry [partridgeberry, partridge-vine] (so named by 1714 because they were considered a food favored by the “partridge.” That bird got the English name from the Latin *perdix*. In Europe, this bird was the grey partridge, *Perdix perdix*. New Englanders began calling the ruffed grouse, *Bonasa umbellus*, a partridge, and then people in Pennsylvania and Virginia added the quail, *Colinus virginianus*.)

[heath-hen, pigeon, pudding, snake, squaw]-plum (Maine, New York)

*Rubhuhnberre* (red hen berry, German)

running box (New York)

squaw vine (said to have been coined by colonists who saw indigenous women using the herb)

twin-berry (the most commonly used modern name for these plants, this refers to the two fruits resultant from paired flowers; sometimes the two fruits are partly attached to each other); two-eyed berry [two-eyed chequer-berry]

Linnaeus ([1753] 1957) gave the scientific name to these small, prostrate, evergreen herbs. He was not the first European to study these diminutive plants, but he was the first to realize that they were unlike any in Europe. The American plants were examined by Leonard Plukenet in 1696, who thought they were *Syringa* (lilacs). John Mitchell, in 1729, thought they were *Chamaedaphe* (Ericaceae). Jan Gronovius, using the John Clayton collection for his *Flora Virginica*, called them a *Lonicera* (honeysuckles). So, Linnaeus commemorated Mitchell’s error by naming the plants after him.

Well toward the end of the 19th century people thought that the *Mitchella* growing in Japan was the same as that in North America (Millspaugh 1892). However, in 1846, P.F.von Siebold (1796–1866) and J.G Zuccarini (1797–1848) realized they were different and named the Japanese plants *Mitchella undulata*. Even then, some considered the Japanese plants only a variety of *M. repens*.

We do not know the provenance of Plukenet’s plants or the information exchanged about them. However, in 1723, Thomas More sent a package of plants from Boston to William Sherard in London. Included was *Mitchella*, which he claimed had leaves that make “the best tea in the world and is counted a great catholicon among us. Colonel Brown, a man of great figure here, told me his body was so big of a dropsie as a sack of malt, but by drinking this tea he soon recovered a very healthy state of body” (More in Coffey 1993).

In 1810, Manasseh Cutler opined: “The leaves are much celebrated by the common people as a diuretic and sweetener of the blood, but are of very little efficacy. It makes an ingredient in their diet drinks.” Physician H.B.Skinner had a different opinion. In his book *The Family Doctor*, published in 1844, he claimed, “a tea of this plant gives much relief to women in labor” (Vogel 1970).

A “Canadian Indian doctor” gave Dr. Stephen W. Williams information in 1849 that he used *Mitchella* with *Spiraea* for the “cure of salt rheum.” Williams valued *Mitchella*

as a diuretic, used extensively for dropsy, and the astringent berries were used to stop diarrhea (Vogel 1970).

Later, Porcher (1863) wrote: "An infusion of the stems and leaves is used in dysuria, its diuretic powers, however, not being of any importance. The 'Cherokee Doctor' declares that the 'decoction taken freely is an excellent article to facilitate childbirth. It should be used daily for two or three weeks before that period!'"

Millspaugh (1892) disagreed with Porcher. He wrote: "*Mitchella* is one of the many plants used by the American Aborigines as a parturient, frequent doses of a decoction being taken during the few weeks just preceding confinement. It has also been found to be a valuable diuretic and astringent, and to have an especial affinity to various forms of uterine difficulties." In spite of the bickering about its effectiveness, *Mitchella* entered the National Formulary where it remained from 1926 to 1947 as an astringent, tonic, and diuretic (Vogel 1970).

All the uses were learned from indigenous people, with tribes through much of the range of *Mitchella* recorded as valuing the plants. Some shared their uses while others were more guarded. The Creeks used the herb to treat fevers according to William Bartram in material written in 1773–1774 (Sturtevant 1955). The Penobscots would only tell Speck that it was to be steeped for use as a medicine (Vogel 1970). Some Ojibwa agreed that they used the plant, giving no details, while others said they smoked it during ceremonies (Moerman 1998).

The Abenaki made a poultice to reduce swelling (Moerman 1998). The Cherokee took it as a diaphoretic and diuretic, and to cure dysentery. They also used it for women's problems, including menstruation pains, sore nipples, and to facilitate childbirth (Hamel and Chiltoskey 1975). The Delaware used it to treat female reproductive organs and sore muscles and stiff joints associated with rheumatism (Moerman 1998). The Iroquois used it as a diuretic, as an analgesic (for labor and other pains), and to stop vomiting, flatulence, fever, and various stomach problems. They also applied it to cuts and rashes to stop bleeding, to prevent rickets, swollen testicles or ruptures, and to cure venereal disease (Moerman 1998). The Menominites steeped the leaves for a drink to stop insomnia (Vogel 1970). The Montagnais made a remedy against fever (Moerman 1998). William Bartram noted in 1774 that the Seminoles extol the plants "as an infalable remedy in Nephritic complaints" (Bartram in Sturtevant 1955).

Vogel (1970) wrote that the plant contains a "bitter principle" and tannin; fruits contain a saponin. Plants also contain glycosides (Swerdlow 2000).

Fruits are edible and may have first been mentioned by Thomas More in 1723 when he wrote: "The berries are rather of an agreeable taste, and are sometimes eaten by children in milk." Yanovsky (1936) simply said the fruits were eaten in Texas and the eastern states. Porcher (1863) added, "The fruit is slightly acid, and is edible." Not everyone was as impressed with the flavor. Fernald et al. (1958) damned *Mitchella* with faint praise when they wrote, "The berries are dry and very seedy, but without disagreeable flavor."

### *Modiola*

(From Latin *modiolus*, Greek *modiolos*, the nave of a wheel)

***Modiola caroliniana*** (of Carolina)

[bristle-fruited, Carolina, Carolina bristly, red-flowered] mallow

*pilapila* [*pila pila*] (Chile)

In his *Species Plantarum*, Linnaeus ([1753] 1957) described 15 species that he considered members of the genus *Malva*. One of those he called *Malva caroliniana*, a name he based on studying living plants at the *Hortus Cliffortianus* and *Hortus Upsaliensis*, and on the publications by John Martyn from 1728 and Jan Dillenius in 1732 on plants grown in London. Both Martyn and Dillenius thought the plants were *Abutilon*, but Linnaeus disagreed.

Conrad Moench disagreed with all three of them. When he studied plants from the New World, he decided these mallows were distinct enough to be in a new genus. He called the species *Modiola multifida* in 1794. It was not until 1831 that George Don realized that the Linnaean name had priority, and he gave us *Modiola caroliniana*.

It is not surprising that there was disagreement about these plants, because we now know that this species represents a monotypic genus with the single species native to the Americas (Mabberley 1997). The species has as a diagnostic trait a transverse partition between the seeds in the fruit locules, but otherwise it looks like *Malva*.

Carolina mallow is considered native from Virginia to Florida and southern Texas. From there, it grows through eastern Mexico and tropical America to Argentina (Fernald 1950, Correll and Johnston 1970). Although reported from California as if native, it was considered naturalized by Munz (1973).

The only record found of indigenous people using the plants was among the Houma. These people of the lower Mississippi River valley made a gargle for sore throat, tonsillitis, and diphtheria (Speck 1941). Neither Porcher (1863) nor Millspaugh (1892) mentioned the species. Similarly, it is absent from the remedies of the Eclectics (Culbreth 1910, Felter 1922) and modern herbal lists (Bown 1995, Duke et al. 2002).

Hocking (1997) does include the plants. He lists *Modiola* as having been used as an emollient and sedative, to treat edema, and for throat problems in Chile. It was used in a cold water extract as a healing bath. Grímé (1976) found records of the plants being used among blacks to treat menstrual problems.

Wunderlin (1998) considers the species native to Florida. I have followed him, although the pattern of distribution and use is suspiciously like that of an introduced plant.

***Monarda***

(Commemorates the Spanish physician Nicolas Bautista Monardes, ca. 1493–1578 or 1588, best known for his 1574 book *Historia Medicinal de las cosas que se traen de nuestras Indias Occidentales que sirven en Medicina*)

***Monarda punctata*** (dotted)*a-shem-bra* (to make sleep; *a-zho n*, I sleep, Osage)horsemint; *witsagwai wi-ti* (horse medicine, Catawba)

*kofucka* ~~t~~*ako* [kofutcka rakko, takko] (*kofucka*, fragrance, ~~t~~*akko*, big or strong, Creek)

rignum (probably derived from *Origanum*, the genus of oregano, New England)

*shinuktileli* [shinuktileli] (*shinuk*, sand [probably originally *shilup*, ghost], *tileli*, to drive out, Choctaw); *sholop tilhi* [shoptilhi'li] (*sholop*, ghost, ~~t~~*ifi*, to send away, Chickasaw)

*sholop tilhi iskanno* (*sholop*, ghost, ~~t~~*ifi*, to send away, *iskanno*, smaller, Chickasaw; probably belongs here); *sholop tilhi losa'* (*sholop*, ghost, *tifi*, to send away, *losa'*, black, Chickasaw; probably belongs here)

John Bannister of Virginia collected the first plants of *Monarda punctata* in 1680 and sent them to Oxford University in England. However, it was best known to Linnaeus from garden and herbarium specimens collected by John Clayton in the 1730s (Reveal 1992a).

Swanton (1928a) found the Creeks using horsemint, and the plant is still used in Oklahoma (Howard 1984). An infusion of the plant causes perspiration. Mixed with *ahá labakca* (*Gnaphalium obtusifolium*) it relieves a delirious patient (Swanton 1928a, Howard 1984). The Alabama, Chickasaw, Choctaw, and Creek used it to ward off rheumatism and to protect the living (Howard 1984). The Catawba used a leaf decoction to relieve headache (King 1984). The Osage used it as a sudorific and for pain relief from coughs, chest complaints, and fevers (Hunter [1823] 1973). It was also used as perfume (La Flesche 1932). The plant also was used by the Delaware, Menomini, Meskwaki, Mohegan, Nanticoke, Navajo, Ojibwa, and probably others (Vogel 1970, King 1984, Moerman 1998).

### *Monotropa*

(From Latin *mono*, one, *tropos*, turn, referring to the summit of the flowering stem being turned to one side)

***Monotropa uniflora*.** From Britton and Brown 1897.

***Monotropa uniflora*** (one-flowered) (= *M. brittoniana*?)

bird's nest (New Hampshire); nest-plant [nest-root]

broom-rape [broomrape] (New Hampshire; usually used for *Orobanche*)

convulsion-root [convulsion-weed] (New Hampshire, New Jersey)

corpse-plant (New Jersey); ghost-flower [ghostplant] (Labrador, Maine, New Brunswick, Newfoundland)

Dutchman's pipe (New Jersey); Indian pipe (in use by 1817); fairy-smoke (Maine); pipe-plant; tobacco-pipe

eyebright (Maine)

fit-root [fitsroot, fit-root-plant] (South Carolina, Maine, New Brunswick)

[American] ice-plant [iceplant] (New Hampshire) *mipitahmaskihkih* (Cree); *weakosinnk* (in a bunch, Potawatomi)

ova-ova (English?)

[one-flowered] wax-plant

*Monotropa uniflora* is a circumboreal saprophyte that extends into the tropics at higher elevations in Central America (Mabberley 1997). Linnaeus ([1753] 1957) knew it from Canada to Virginia, and accepted the name *Monotropa* as proposed by Gronovius. Those who preceded his *Flora Virginica* considered it an *Orobanche*. Apparently, there are only two species in the genus, this and *M. hypopitys*.

Millspaugh (1892) recorded that the Americans learned about medical applications of these plants from the indigenous people; his source was Rafinesque's *Medical Flora*. Rafinesque said that juice from *Monotropa* "mixt with water deemed specific lotion for sore eyes" by native people. Porcher (1863) wrote, "This is used by the steam practitioners." Others consider it good for spasms and fainting spells, which explains some of the common names (Coffey 1993). The Potawatomi used the root for "female troubles" (Smith 1933).

***Morinda*: Cheeseweed**

(Ostensibly commemorates the French physician Louis Morin, 1636–1715, although Linnaeus probably composed the name from the Latin *morus+indicus*, Indian mulberry)

***Morinda royoc*.** a. Flowering and fruiting branch, b. Syncarp, with young fruits and flowers, c. Flower, longitudinally dissected, d. Floral diagram, e. Branch with fruit. *Drawn by Priscilla Fawcett. From Correll and Correll 1982.*

Although it is also called Indian mulberry or red gal [redgal], most people who have been in Florida a long time call these shrubs cheeseweed. Technically, the plants are *Morinda royoc*, and belong in the Rubiaceae with coffee (*Coffea*), quinine (*Cinchona*), and gardenia (*Gardenia*).

I did not really understand why the shrubs were called cheeseweed until an “accident” by one of my students. She was gathering data for me on endangered species when she found a low shrub with small white flowers she did not know in one study plot. She put the fruiting branch in the back of her car at the end of a long day drove home and forgot about the branch. The next morning she drove to school early and parked as usual. That evening when she returned and opened the steamy hot car, an overpowering stench made her stagger backward. She described the odor in various ways, but the least damning comparison was to hot Limburger cheese. So, perhaps cheeseweed is as good a name as any.

Nearby Florida in the Bahama Islands, people call the species duppy poison, rhubarb, stiff cock, wild mulberry, yaw weed, and yellow ginger. Those names are related to several of the uses that people have for them there and elsewhere, as aphrodisiacs, medicines, and dyes.

The meanings of most of the words in these names are obvious, but “duppy” may not be. “Duppy” appeared in English literature for the first time about 1774. The word originated in the language of the Ashanti of Ghana, a matrilineal Akan people who brought the word to the Caribbean when they were sold there as slaves. The first statement published about their beliefs concerning duppies in Jamaica was, “They firmly

believe in the apparition spectres. Those of deceased friends are *duppies*; others...like our raw-head-and-bloody-bones are called *bugaboos*." By the 1830s, the view had changed so that both duppies and bugaboos were feared. Nowadays that view has changed again, and duppies are mostly considered mischievous, as in the expression, "Is the dutty duppy man sweet?" (The dirty ghost did it). One of the things duppies seem to enjoy is throwing stones (Williams 2002). The name "duppy poison" means not fit for human consumption, but it can also mean duppies use it for poison, or that it can be used to poison duppies.

A widespread use is as an aphrodisiac. Some of the names are uneasy allusions showing as much fear as belief. In addition to the names from the Bahamas, there are *duivel's brood* (devil-spawn), *loembra maatsjoe* (woman's bush?, Aruba, Bonaire, Curacao), *palo garañon* (tree's semen), *pom di djabel* [*parn die diaabel*] (devil's spawn?, Aruba, Bonaire, Curaçao), *pepa de ratón* (rat's seed, Venezuela), and strong back (Jamaica). *Morinda* may be used alone or mixed with other plants; both *Chiococca alba* and *Smilax havanensis* have been added to the mixture (Ayensu 1981). Although some consider *Morinda* for men, others recommend it for women to regulate menstruation (Morton 1981).

Medicines of other kinds are also common. Some of the names relating to them are *curamagüey* (literally, cure's *Agave*, Cuba), painkiller (Jamaica), *piñipiñi* (Cuba), *raíz de indio* (Indian root), and probably *xcruz che'* (plant in the form of a cross, Maya, Yucatán). The Maya of Belize say *ax-ak* (*ax*, verrugose or lumpy, *ak*, vine). One of the common uses applied from Cuba to Curacao is as a laxative or, depending on dosage, a purge. Names probably relating to that use are *bataata heel* (complete potato, Aruba, Bonaire, Curaçao), *estologe* (for the stomach, Hispaniola), *paja de ratón* (rat's straw), *piña kan* (snake's pineapple, Yucatán), *revienta caballo* (horsesplitter, a name generally applied to a poisonous member of Caribbean Campanulaceae, Cuba), rhubarb root (Cayman Islands), and *ruibarbo de la tierra* (wild rhubarb, Cuba). Wart vine (Belize) is unique.

Fruits are eaten by people and hogs. The latter use is reflected in the Jamaican name hog apple.

In Haiti, the Bahamas, and other places, *Morinda* is considered tonic, stomachic, and useful against diarrhea (Liogier 1974, Ayensu 1981, Morton 1981). One of the tonic remedies is to mix it with *Cissus verticillata*, *Smilax* spp., and *Desmodium incanum*. Fruits are used to make an antiscorbutic, depurative drink (Duke 1968, Liogier 1974). Young leaves have been eaten as a potherb, and the seeds of some species are roasted and eaten. The name sore throat (Bahamas) reflects that the leafy stems are boiled and the liquid gargled for that problem. The decoction is also used to ease teething pain in infants (Liogier 1974). Generally, the plant is analgesic and the wilted leaves may be pressed on painful parts of the body or used as poultices for headaches. Crushed leaves in lard or camphor are placed on the head for colds and neuralgia. In Haiti, it is considered a contra-venom against the *Tuatua* (Liogier 1974).

*Morinda royoc* is called yaw weed, and has been famous for treating that terrible malady since at least the 1800s. Although it is a disease unfamiliar to most people in temperate zones, it formerly was common in the Caribbean where it is thought to have been introduced by slaves from sub-Saharan Africa (Desowitz 1997). The cause is *Treponema pertenue*, a nonvenereal spirochete transmitted by contact other than sexual.

Although the problem begins with an innocuous appearing lesion of the skin, it later destroys not only the skin but also the underlying bone.

The genus is a noted dye plant. Names for *M. royoc* alluding to dyes are *paaloe zapateero* (shoemakers tree, Aruba, Bonaire, Curaçao), red gal (Jamaica), *safrán* (saffron, usually a name for *Cucurma longa*, Haiti), *safrán du pays* (country saffron, Haiti), *safrán du St. Domingue* (Santo Domingo saffron, Haiti), and yellow root (Cayman Islands). Colors vary with mordants and may be either saffron or red (Duke 1968, Morton 1981).

In English-speaking regions, *M. royoc* is sometimes called Indian mulberry. However, that name is used mostly for the related Asian plant, *M. citrifolia*. Linnaeus named both *M. royoc* and *M. citrifolia* in 1753. He based *M. citrifolia* on Rheede's *Flora Malabarica* where it was called *cada-pilava* (misspelled by Linnaeus as *coda-pilave*; modern spelling, *kadapilavu*; today the name of the breadfruit *Artocarpus altilis*) in the Malayalam language. The modern name of *M. citrifolia* in Malayalam is *kakapazham* (*kaka*, crow, *pazham*, fruit). Of course, the genus name is another of Linnaeus's dual meanings. The specific name *royoc* came from Charles Plumier's *Royoc humifusum*, *fructu cupressino* (the humble *royoc* with the fruit of the cypress), although no one knows where he got the word *royoc*. Perhaps it is based on *hoyoc*, the Mayan name for *M. yucatanensis*.

Roig (1945) recorded that the roots of *M. royoc* contain tannin, agalic acid, mucus, and calcium oxylate, and no subsequent chemical studies appear to have been made. Considering the chemicals found in other species, that seems a particularly short-sighted void. Many other species in the genus have been used by people, with 26 mentioned in the journal *Economic Botany* in the first 50 years of its existence (Kaplan 2001). In *M. citrifolia* alone, chemicals have been found that are analgesic, insecticidal, nematocidal, antineoplastic, and immunomodulative.

It should come as no surprise that *M. citrifolia* also has an impressive history of use because it is important to people from at least India to Hawaii (Watt [1889] 1972, Burkill 1966, Degener 1973, Kaaiakamanu and Akina 1976, Heinicke 1985, Aalbersberg et al. 1993, Dittmar 1993, Dornenburg and Knorr 1994a,b, Hagendoorn et al. 1994, Farine et al. 1996, Dixon et al. 1999, Hirazumi and Furusawa 1999).

Other species that have been used by people indicate analgesic, antifungal, antileukemic, antimicrobial, antinematodial, antineoplastic, antiviral, cytotoxic, and hypoglycemic activities (Durodola 1974, Chang et al. 1982, Younos et al. 1990, Kamanyi et al. 1994, Rath et al. 1995, Kwo and Craker 1996, Bankole 1997, Mackeen 1997, Ali et al. 2000), with possible control of fascioliasis and schistosomiasis, *Plasmodium falciparum*, trypanosomes, and ulcers (Adewunmi and Kayode Adesogan 1984, Asuzu and Chineme 1990, Koumaglo et al. 1992, Udem et al. 1993, Olajide 1998). Many of these effects are due to a large number of anthraquinones, iridoid glycosides, flavone glycosides, flavonoids, sterols, and nitrosatable amines (Singh and Tiwari 1976, Adesogan 1979, Vermes and Wagner 1980, Venkateshwar Rao and Rao 1983, Poulsen et al. 1991, Srivastava and Singh 1993, Dryas et al. 1994, Legal et al. 1994, Cimanga et al. 1995a,b, 1997, Leistner 1995, Uhegbu and Madkuagwu 1995, Ismail et al. 1997, Wang et al. 2000, Sang et al. 2001). Given the similar uses for *M. royoc*, it surely contains related chemicals.

Cheeseweed grows in southern Florida from Martin County around the southern tip to Lee County. Disjunct plants are known from as far north as Cape Canaveral in Brevard

County on the east coast and Hillsborough County on the west coast. The shrubs also grow in the Bahamas, Cuba, Hispaniola, Jamaica, Grand Cayman, and southern Mexico to Ecuador and the northern coast of Venezuela. *Morinda royoc* is absent from Puerto Rico and the Lesser Antilles. There are now 80 species known in the genus, with all but about 22 species confined to the Old World tropics. The related *M. yucatanensis* is called *xhoyoc* [*joyoc*, *hoy ok*] or *x-y en-cab* [*xhoyenkab*] (Maya) and *piñuela* (little pineapple, Yucatán). However, not all fruits called pineapples are as tasty as their namesake.

### ***Morus*: Mulberry**

(From classical Latin *morum* and Greek *moron* for the mulberry and blackberry)

***Morus rubra*.** From Sargent 1905.

Humans and other vertebrates near mulberry trees (*Morus rubra*) quickly become aware of the edible fruits when they are in season. If the people do not notice them immediately, the red-black stains left by the birds as they digest the sweet fruits are ample indication of their value. Although people throughout temperate Europe now prize mulberries, that is a comparatively recent phenomenon.

No mulberries are native to Europe or most of the Mediterranean region; only the black mulberry (*M. nigra*) grows wild in northern Persia on the shores of the Caspian Sea (Hedrick 1919, Mabberley 1997). Pliny (A.D. 23–79) noted that *M. nigra* was successfully reared in Italy by Lucius Vitellus after several failed attempts. At the time of Paladius and Athaneus (A.D. 170–230), the tree was uncommon. Silk culture under Justinian (A.D. 483–565) gave *Morus* new importance and it spread, reaching France in 1500 (Hedrick 1919). The white mulberry, *M. alba*, was brought from Asia into the Levant and then into Tuscany about 1434 (Hedrick 1919). Subsequently, *M. alba* replaced *M. nigra* in raising silkworms.

Although it hardly seems plausible, the word “mulberry” is based on the Latin *moms*. From *morus* or *morum* in Latin, the fruits became *mora* in Italian, Spanish, and Portuguese, and *mûre* in French. *Morus* plus berry was transcribed into *mulbere* in Old High German to become *Maulbeer* in modern German, *moerberie* in Dutch, and mulberry in English.

Mulberry is first mentioned in print in English in 1382: “The kyng saue in to Jerusalem...cedres as long mulberries (Vulg. *cedros quasi sycamoras*).” The use of the word *sycamoras* is not an accidental comparison. Greeks like Theophrastus (372–287 B.C.) called the mulberry *sukamnos* or *sykamnos* [modern Greek=*sycaminus*]. The Greek

words *sykamnos*, *sycamore*, and *sycamore* are variations of *sykomoros* (*sykon*, fig+*moros*, mulberry). To further complicate the situation, “sycamore” was first used in English in 1388 to refer to a fig (*Ficus*) then to a maple (*Acer*), and after the New World was discovered, yet another tree (*Platanus*). Cognate words occur in Hebrew as *shiqmah* and in Sumerian as *sukannu*, although in the Bible the tree is also *tut* in Macabees and *mesukan* in Isaiah (Zohary 1982). *Mesukan* is cognate to *messikanu* in Sumerian.

When Europeans arrived in the New World, they found another species, the red mulberry *M. rubra*. Linnaeus knew this tree from the publications of Leonard Plukenet who called it *Morus virginiensis arbor*, *loti arbor is ins tar ramosa, foliis amplissimis* (mulberry tree from Virginia, a tree branched like lotus, leaves large).

Many early explorers of the New World commented on the native use of the trees. Hernando de Soto noted mulberries cultivated in what is now the Panhandle of Florida while en route to Apalachee in 1540 (Standley 1920–1926, Swanton 1939). Barrientos (1567) wrote that the de Soto expedition, upon arriving at *Cofitachiqui*, a Muskogee village in Georgia, found that “mulberry groves are so thick that it is necessary to cut them down in order to make plantings.”

In 1682, Henri de Tonti was traveling with Sieur de la Salle down the Mississippi. In a Taencas (Natchez) village he “saw the chief seated on a camp bed... surrounded by more than 60 old men, clothed in white cloaks, which were made by the women out of the bark of the mulberry tree” (Tonti in Borland 1965).

William Bartram, traveling near Wrightsborough, Georgia in the 1770s, also saw cultivated trees. Of old Creek villages Bartram says: “These are always on or near the banks of rivers, or great swamps, the artificial mounds and terraces elevating them above the sur-rounding groves. I observed, in the ancient cultivated fields... *Moms rubra*” (Bartram [1791] 1958).

Red mulberry was used at least by the Alabama, Atakapa, Biloxi, Catawba, Cherokee, Chickasaw, Chitimacha, Choctaw, Comanche, Creek, Delaware, Iroquois, Koasati, Lakota, Meskwaki, Natchez, Ofo, Omaha, Onondaga, Powhatan, Rappahannock, Timucua, Seminoles, Shawnee, and Yuchi (Yanovsky 1936, Swanton 1946, Moerman 1998). The species is native from New England (western Massachusetts, Connecticut, Long Island), southern Ontario, west to Michigan, southern South Dakota and Texas, and southward to the tip of mainland Florida. In the southeast, at least the Choctaw, Creek, Koasati, and Yuchi had a “mulberry month.” The Choctaw called it *hashe* [*hvsh*] *bihi* (*hvsh*, month, *bihi*, mulberry).

The Onondaga call the fruit *sachissegóna òchia* (*òchia*, fruit). Algonquian speakers in New England, the Delaware, call the mulberry tree *oakhattim inschi*. Strachey ([1612] 1953) recorded the Powhatan name *muskimins*. The Shawnee, another Algonquian tribe, say *mtakwa-palwa*. Louisiana Siouxan-speakers said *ansankùdi* (Biloxi) and *fafanaki* (Ofo). To their west the Atakapa said *cec*. Catawba said *tcutca*?

There are records of several cognate words for mulberry in the southeast. These include *bí: hî* [*bihi*, *behe*] (Mikasuki), *ke* [*kei*, *ki*] (Muskogee), *ki: han* (Creek), *bihi* (Chickasaw), *bihi* (Choctaw), *bihi* [*bihala*] (Alabama), *bihald* (Koasati), and *kuwa* [*ku: wa*, *koo wah*] (Cherokee).

The importance of the species to these native people is apparent in names of towns (Swanton 1946). There was a town called *Kayomalgi* (mulberry place) by Gatschet, which Swanton (1946) also writes as *Cayomulge*. In both instances, the word for

mulberry is *cayo*, equivalent to Creek *kei* or *ke*. The Cherokee have two or more settlements in South Carolina named *Kuwahi'yi*, abbreviated *Kuwahi'*, "Mulberrygrove place."

Although the most frequently used names in English are simply mulberry or red mulberry, *M. rubra* is also called black mulberry, bulberry, Virginia mulberry, and Virginia mulberry tree. To the French it is *murier sauvage* (wild mulberry tree), while the Spanish say *moral* (mulberry grove), and the Germans *Maulbeerbaum* (mulberry tree).

The fruit was the part of the plant most used by people in North America, at least in its season. The earliest record is from the de Soto expedition in the Muskogee village *Cofitachiqui* (Barrientos 1567). The chroniclers recorded, "From the mulberries the Indians make raisins [*pasas*], which are good to eat." Various people employed it in basically the same ways, either eaten fresh or dried, and mashed and made into cakes for future use. Probably the early use was like the Iroquois who soaked the dried fruit cakes in warm water during the winter and then cooked them into a sauce or mixed them with corn bread.

The Cherokee historically mixed the berries with sugar and cornmeal to make dumplings (Hamel and Chiltoskey 1975). There are records of the Cherokee, Comanche, Iroquois, Omaha, and Seminoles eating the fruits, but it is likely that all people within the range of the species found *Morus* welcome food. Europeans and Americans in the New World quickly learned to make the fruits into jelly, jam, pies, and other sweets.

The Seminoles and probably others made bows from the branches (Sturtevant 1955). Americans used the wood for casks and tubs, fence posts, cross ties, furniture, and boats. Throughout the southern states, the trees were planted as food to fatten hogs and for poultry (Sargent 1905). Several groups used the inner bark to make cloth, including the Caddo and Tonkawa of Texas (Newcomb 1961) and the Natchez of Louisiana (Tonti in Borland 1965).

One of the first records of indigenous mulberry dye came from Frenchman Jacques Le Moyne during his stay in northeastern Florida (Swanton 1946). He recorded that the Timucua used the trees to dye materials in the mid-1560s. Colors derived from *Morus* vary depending on whether the leaves, stems, or fruits are used. Tans and yellow-greens are obtained from branches with an alum mordant, while graylavender to purple comes from berries with alum (Tull 1999). Cannon and Cannon (2002) noted that dyes from *Morus* result largely from the flavonol morin but rutin is also present. Bark and wood contain various flavones, including mulberrin, and these create golden yellows, bronze, olive, and browns with different mordants.

A mulberry caveat is that unripe fruits and sap from other parts can cause gastrointestinal distress and skin rash (Tull 1999). That toxicity also suggests that bioactive compounds are present. The mulberry was considered medicinal by the Alabama, Cherokee, Creek, Meskwaki, and Rappahannock (Moerman 1998). The Alabama and Creeks used a decoction of the roots to treat urinary problems (Swanton 1928a, Taylor 1940). The Cherokee took an infusion of bark to expel worms, to stop dysentery, and as a laxative (Hamel and Chiltoskey 1975). The Meskwaki considered the root bark a medicine for any illness. The Creeks also used the root as an emetic (Swanton 1928a). The Rappahannock rubbed on the sap to cure ringworm. As late as Millspaugh (1892), the bark was still being recommended as a cathartic and anthelmintic. Krochmal and Krochmal (1973) noted that the fruit could be made into a cooling drink to reduce

fever, and it was also used as a mild laxative. A decoction of the outer bark was used to treat worms, while the inner bark was scraped and boiled to make a tea used as a children's laxative.

Little is known about the chemistry of *M. rubra* beyond the phenolics in the wood (Deshpande et al. 1974). However, a great deal is known about other species of *Morus*, and surely much of that applies to *M. rubra*. Various parts of *Morus* contain alkaloids, coumarins, cyanidin, ecdysterone, flavones, flavonoids, inokosterone, isoquercitrin, mucilage, pectin, phenolics, tannins, and triterpenoids (Kino et al. 1977, Hsu 1986, Nomura et al. 1988, Mihara et al. 1995, de Souza et al. 2000, Kim et al. 1999, 2000, Asano et al. 2001, Nomura 2001, Shi et al. 2001a,b, Kusano et al. 2002). The extracts are considered antibacterial, antiinflammatory, antioxidant, antipyretic, diuretic, hypotensive, immunomodulating, and sedative (Chatterjee et al. 1983, Hsu 1986, Yen et al. 1996, Chen et al. 1998, Kim et al. 2000). In addition, *Morus* has shown potential for treating diabetes (Ionescu-Tirgoviste et al. 1989, Basnet et al. 1993, Chen et al. 1995a,b, Nojima et al. 1998, Limus et al. 1999, Andallu et al. 2001, Kubo et al. 2001, Petlevski et al. 2001) and hypolipidemia (Yassin et al. 2001).

Often when I see a mulberry tree I am reminded of the children's rhyme "Here we go round the mulberry bush." That rhyme always seemed odd to me because the mulberry is a tree, not a bush. It turns out that the use of the word "mulberry" in English is equivalent to Spanish where *mora* also means blackberry (*Rubus*). Vickery (1995) has traced the history of the word and found that the "mulberry bush" in the game was actually a *Rubus* and not a *Morus*, and the mixing of their names goes back to Horace (65–8 B.C.), Vergil (70–19 B.C.), and Ovid (43 B.C.–A.D.?17). Indeed, a glossary published in the 11th century by R.P. Wülcker (Wright 1884) recorded that *mora* was used as a generic name for all berries.

One should be wary of identifications whether they are common names or Latin names.

### *Muhlenbergia*

(J.C.D. von Schreber named this in honor of Gotthilf Heinrich [Henry] Muhlenberg, 1753–1815, a German-American Lutheran minister and amateur botanist)

#### *Muhlenbergia capillaris* (hairlike)

[long-awned] hair-grass [hairgrass] (Texas, Bahamas, Puerto Rico); *yerba de pelos* (hair grass, Puerto Rico)

[Gulf, hairy-awn, slender] muhly (Texas)

purple-grass (Bahamas, Puerto Rico)

***Muhlenbergia capillaris*.** Drawn by  
Mary Wright Gill. From Hitchcock and  
Chase 1950.

*pvhe cvmpv* (*pvhe*, grass, *cvmpv*, sweet, Muskogee); sweet-grass  
(English name used by Big Cypress Seminoles)  
*rabo de pavo real* (peacock's tail, Puerto Rico)

Jean Baptiste Lamarck called this grass *Stipa capillaris* in 1791, only 2 years after Schreber proposed the genus *Muhlenbergia*. Subsequent exploration found other species, and the genus has grown to about 160 species in the world tropics (Mabberley 1997).

This species has a long history of use as fodder and a forage plant (Hocking 1997). Less well known is that the Seminoles now use, and probably historically used, it to make baskets. The weavers on the Big Cypress Seminole Reservation call the stems "sweet-grass," and books typically translate that as *Glyceria septentrionalis*, *Anthoxanthum odoratum*, or *Hierochloa odorata* (Fernald 1950, Radford et al. 1968). None of these genera is native to Florida, with all having ranges farther north.

Independent examination by Bennett (personal communication, 2000) and by me revealed that the Seminoles use several grass species. The individuals we talked with call them all "sweet-grass" and were aware that there were different kinds. Both *M. capillaris* and *Aristida* were used.

The baskets now offered by the Seminoles for sale in their shops are a design adapted from the blacks who lived with them in the past. The coiling techniques used to make the items resemble those employed by the Gullah (Geeche) of the coastal sea islands of the Carolinas, Georgia, and Florida. PreEuropean baskets in the Southeast were woven and not sewn (Swanton 1946, Cooke and Sampley 1947).

*Myrcianthes*

(Named by Otto Carl Berg from *myrcia*, perfume+ *anthos*, flower, for having flowers like *Myrica*)

*Myrcianthes fragrans*. a. Branch with flowers, b. Distal part of flowering branch, with three-flowered dichasial unit; the bracteoles subtending lateral flowers have fallen, c. Flower, from above, d. Flower, longitudinally dissected, e. Floral diagram, f. Branch with fruit, g. Fruit, h. Fruit (two-seeded) in transverse section, showing fleshy cotyledons of embryo. *Drawn by Priscilla Fawcett. From Correll and Correll 1982.*

*Myrcianthes fragrans* (perfumed) **var. *simpsonii*** (for Charles Torrey Simpson, a naturalist and book author in Miami, well known in the early 1900s)

*ahitiyã*: *ncó*: *bî* (*ahi*, tree, *tiyán*, twisted, *có*: *bî*, big, Mikasuki);  
*[tokina:nafákko]* *tokina*: *nardkko* (*eto*, tree, *konhe*, crooked, bent, *lakko*, big,  
Creek)

*arrayán* (well rooted, Dominican Republic)

*bois d'Inde* (Indian bush, Haiti)

*ciya:fá.põmi:kî* (to make ax handles, Mikasuki)

*goyavier bois* (guava tree, Martinique); *guayabillo* (little guava,  
Tamaulipas); *guayabito* (little guava, Venezuela); *guayabacón*  
(*guayabacdn*, Taino name for a *Myrica*, Puerto Rico)

*merisier* (cherry tree, Guadeloupe)

naked-wood [nakedwood] (Florida, Bahamas; also a name given to  
*Colubrina*, which see)

pale stopper (Bahamas); Simpson's stopper (Florida)

perfume bush (Bahamas)

*pimienta* (spicy one, Cuba); *pimientilla* (little spicy one, Tamaulipas)

Neither Morton (1981) nor Wunderlin (1998) recognizes varieties within the species, but var. *simpsonii* is readily distinguishable in the field. Although *Myrcianthes fragrans* var. *simpsonii* is endemic to Florida, the other variety is more widespread. In Mexico the species grows from Durango, San Luis Potosi, Tamaulipas, Veracruz, and Tepic, and throughout Central America and the Caribbean, to Colombia and Venezuela. Mexicans use the wood for building homes and other purposes (Standley 1920–1926) as do people in the Caribbean and elsewhere (Morton 1981). The Seminoles use the wood for pestles, food paddles, blowgun darts, and ax handles (Sturtevant 1955). Sometimes they called it *ciyá:fá.pomí:kî* (to make ax handles).

In the Caicos Islands a decoction of branch tips is a febrifuge, a remedy for aches and pains, and a perfume. Elsewhere in the Bahamas, the decoction is mixed with *Pluchea rosea* (camphor-weed) and used to reduce labor pain (Morton 1981). It is mixed with *Amyris elemifera* to drink or to bathe in to treat the flu (Ayensu 1981).

### ***Myrica*: Wax Myrtle**

(Greek *myrike*, the name of the tamarisk, *Tamariscus*, or some other fragrant shrub; perhaps from *myrizein*, to perfume)

The view from my office windows when I first went to Florida was of a 90-plus acre triangle of land that retained much of the natural vegetation (Austin 1990). Scattered throughout the parcel were numerous wax myrtle bushes, scientifically *Myrica cerifera*. Each fall and winter, the tree swallows (*Tachycineta bicolor*) would come into the area in flocks of several thousand. The small birds, normally insect eaters during the summer, would spiral down to the wax myrtle bushes and snatch off berries, or land and then

**Myrica.** a to g, *Myrica cerifera*. a. Branch with staminate flowers, b. Branch with pistillate flowers, c. Branch with fruit, d. Top of leaf. e. Underside of leaf. f. Staminate flowers, g. Fruit, h to q. *Myrica heterophylla*. h. Branch with staminate flowers, i. Branch with pistillate flowers, j. Branch with fruit, k. Top of leaf. l. Underside of leaf. m. Cluster of staminate flowers, n. Cluster of pistillate flowers, o. Pistillate flowers, p. Pistil, q. Fruit. Drawn by Vivian Frazier. From Correll and Correll 1972.

fly back up into the column. When I first saw this, there were so many birds in the group I thought it was a tornado. This process would continue until individual bushes were stripped of their berries, and then the funnel would move on to the next shrub.

I have been in the field when one of these flocks moved in, and the sound made me think there was a rain shower coming toward me. The sound resulted from a “shower” of

wax myrtle seeds passing through bird guts and raining down around me. They are impressive displays of birds dispersing the seeds of their food plants.

Wax myrtle is more temperate than tropical but grows in both regions. The plants range from New Jersey to Florida, Bermuda, the Bahamas, the West Indies (Cuba, Hispaniola, Puerto Rico to Guadeloupe), west to Arkansas and Texas, from Veracruz and Chiapas to Yucatan, and Mesoamerica south to Costa Rica. *Myrica cerifera* became known to Europeans when it was illustrated by Mark Catesby (1731–1732). He called the plants *Myrtus brabanticae similis caroliniensis humilior, foliis latioribus & magis serratis* (similar to *Myrtus* from Belgium, but from Carolina and smaller, leaves wider and larger teeth) and put them in two different drawings (plates 13, 69).

Catesby was not the only person who thought the plants looked like myrtle (*Myrtus communis*). People from the southern United States to Belize call them mickleberry (Carolinas), muckle (Carolinas), muckleberry (Carolinas), myrtle (Belize), or sweet myrtle (Carolinas). Those names are variations of “myrtle.”

Regarding use of the wax by people in the New World, Catesby wrote: “In November and December, at which time the Berries are mature, a Man with his Family will remove from his Home to some Island or Sandbanks near the Sea, where these Trees most abound, taking with him Kettles to boil the Berries in. He builds a Hut with Palmetto-Leaves, for the shelter of Himself and Family, while they dry, which is commonly Three or Four Weeks.

“The Man cuts down the Trees, while the Children strip off the Berries into a Porridge-Pot, and having put Water to ‘em, they boil them ‘till the Oil floats, which is skimmed off into another Vessel. This is repeated until there remains no more Oil. This, when cold, hardens to the Consistency of Wax, and is of a dirty green Colour. Then they boil it again, and clarify it in brass Kettles, which gives it a transparent Greenness.

“These candles burn a long time, and yield a grateful Smell. They usually add a fourth Part of Tallow, which makes them burn cleaner.”

Use as a wax source for making smokeless candles was a long-established practice by the time Catesby recorded it, and many people note that in their plant names. They call the shrubs *arbol de cera* (wax tree, Hidalgo, Veracruz, Oaxaca, Dominican Republic), *arbre a suif* (tallow shrub, Canada), candleberry (USA), candleberry myrtle (Catesby 1731–1732), *cera vegetal* (vegetable wax, Central America), *cerero* (waxy one, Puerto Rico), *eerier* (wax tree, Houma, Louisiana), *drier de la Louisiane* (Louisiana wax tree, USA), *polo de cera* (wax tree, Dominican Republic), southern wax myrtle, tallow berry (Carolinas), tallow shrub (USA), wax berry (Puerto Rico, Jamaica), southern wax myrtle (Florida), wax tree (Bartram [1791] 1958), and wax wood (Jamaica). The wax is harder and more brittle than beeswax, and it is still used to make and scent soap in North America and the Caribbean (Bown 1995).

The Houma also used *Myrica heterophylla* (evergreen bayberry) berries to make candle wax (Speck 1941). If that is any indication, they probably also used *M. inodora*, as it was being used ca. 1800 by inhabitants of Alabama to make candles (Hocking 1997). Indeed, Bartram ([1791] 1958) found it on the Upper Tensaw River near Hall’s Creek, Alabama, where it was used for “production of wax for candles, for which purpose it answers equally well with beeswax, or preferable, as it is harder and more lasting in burning.”

Shortly after Catesby's book was published, the plants were growing in the garden maintained by wealthy Anglo-Dutch financier George Clifford at Hartekamp in Haarlem, Holland, where Linnaeus studied them for his book *Hortus Cliffortianus* of 1738. About 10 years later Linnaeus recorded the plants growing in the botanical garden at Uppsala, Sweden, where he was a professor. It was from Catesby's drawings and from personal knowledge of living plants that Linnaeus gave them the name in use today—*Myrica cerifera* (wax bearing).

The Latin name refers not only to the fruits as a source of wax for making candles, but also to the fragrance of the leaves. That fragrance also was enjoyed as a flavor in foods. Names that reflect that use are bayberry (USA, Puerto Rico), bayberry tallow (USA), southern bayberry, and sweet bay (Carolinas). The name "bayberry" is redundant because "bay" comes from the Latin *baca* (berry), through the Old French *baie*, to *beg* in Old English in the 11th century, and finally to *baye*, *baie*, or *bay* about 1398.

"Bayberry" appeared in English about 1576 when Henry Lyte translated the Dutch herbalist Rembert Dodoens's comments on the Old World species *Laurus nobilis* as, "Called in Latine *Lauri baccae*, in English Bay berries." Sweet bay is a name for *M. cerifera* and for *Magnolia virginica*. The name spicebush indicates to others that the leaves were used to season foods, but that name is typically applied to *Lindera benzoin* (which see).

Food was not the only item that people flavored with the leaves of *Myrica*. The Seminoles call the shrubs *cowā:nôcā:pī* [*tcowano'tcapi*, *cowaanocaapi*, *chowane emochaape*, *chuono chopp*, *chuone em ochopee*] (*chowane*, fly, *em*, its, *ochaape*, garden, Mikasuki) or *soli:capī* [*shule chopee*] (*sule*, buzzard, *cupof*, garden, Creek) and their neighbors say *hungwekilo* (*wiikih*, heavy, Choctaw). All three used the leaves to make their tobacco last longer or as a substitute for *Nicotiana* (Sturtevant 1955, Bennett 1997). That usage is clearly indicated in the name used by their relatives the Alabama, who called these shrubs *ito hakchomma* (*ito*, tree, *hakchomma*, tobacco) or *choyyiniyaachi* [*choyyinihaachi*] (*choyyiniha*, resin, *chi*, small). The Koasati simply said *ittoikillo* (*ittó*, tree, *ikillo*, undying).

Other names for the plants record different views. In the Caribbean, they are *arrayán* [*arraján*, *arraigan*] (well rooted, also applied to *Eugenia*, *Myrcianthes*, *Myrciaria*, Cuba, Puerto Rico), *caca-ravet* (*caca*, feces, *ravet*, rat, Guadeloupe, Martinique), *perico* (a type of parrot, Hispaniola), *souse bastardo* (false willow, Belize), and *tiguapén* (*tigua* is an aquatic bird, Hispaniola). In Mexico, they are *chac-ol'ol* [*chacolol*] (*chak*, red, *ol'ol*, renewal, in reference to young leaves, Maya, Oaxaca), *gua-ut*, or *huanacanalá* (Veracruz, Oaxaca).

Medicinal uses are reflected in the names tea-bark (Belize, Carolinas), tea-box (Belize, Carolinas), and wild tea (Carolinas). Millspaugh (1892) said the first record of using the plants as medicine was in Louisiana in 1722. That document noted that the water in which the wax had been boiled was a cure for the most violent cases of dysentery. Plants were used by the Choctaw (Bushnell 1909), Houma (Speck 1941), Koasati (Taylor 1940), and Seminoles (Sturtevant 1955), and the Houma and Koasati lived near the area where medical use was first recorded by Americans. Usually, European-derived people learned to use New World plants from natives whether or not history has recorded that exchange.

Other people who used *Myrica cerifera* as medicine were the Micmac of New Brunswick and Nova Scotia, although all the people in eastern North America used other

species of *Myrica* as medicine, including at least the Bella Coola, Woodlands Cree, Delaware, Mohegan, Ojibwa, and Potawatomi (Smith 1933, Moerman 1998). The Micmac used *M. cerifera* as an analgesic, an exhilarating beverage, a diuretic, emetic, febrifuge, gargle for inflamed tonsils, to treat headache and external inflammation, as a vermifuge, and for stomachache. People in South Carolina, the Caribbean, and Central America used the plants in the same ways (Martinez 1969, Morton 1974, 1981). Eclectic physicians (Felter 1922) considered the wax (“myricin”) useful for problems of the mucous membranes such as “stomatitis, nursing sore mouth, ulcerated fauces [throat], bowels and stomach” (Millspaugh 1892). Murphee (1965) found people in the Panhandle using it to speed up labor during childbirth. The plants are still considered medicinal by the Herb Society of America, with mostly the same uses as in the 1700s (Bown 1995).

Among the bioactive chemicals in *M. cerifera* are the flavonoid glycoside myricitrin, the triterpenes myricadiol, taraxerol, and taraxerone, and myrica acid, an oleanane triterpenic acid (Paul et al. 1974, Nagai et al. 2000). Also, the nonpeptide endothelin receptor antagonist triterpenoid myriceric acid A is known (Fujimoto et al. 1993, Mihara and Fujimoto 1993, Sakurawi et al. 1996). *Myrica cerifera* also contains palmitic acid and tannins (Kapadia et al. 1976).

In German *M. cerifera* is *Wachsbush* (wax bush) or *Wachsgagle* (wax gale). The latter name compares it with the European and American *M. gale*. That shrub from Europe is called *roid* (Gaelic), *bwrle* (Welsh), and *pors* (Norwegian, Swedish). In northeastern North America these plants are sweet gale, meadow-fern, *piment royal* (royal pepper, Canada), or *bois sent-bon* (sweet-scent bush, Canada).

You may be more familiar with *Myrica* than you think because the leaves also are used to improve the foaming of beer. The next time you drink beer, especially European brands, remember that the head is probably due to *Myrica*.

# N

## *Nelumbo*

(Linnaeus first used *nelumbo* in 1753 for the species name of the sacred lotus, now *N. nucifera*; he derived *nelumbo* from the Sinhalese name, *nelun* [*nelum*]; in 1763, Michel Adanson reapplied the word to the genus)

*Nelumbo lutea*. a. Habit, b. Pod, longitudinal section, c. Seed. d. Stamens. Drawn by Regina O. Hughes. From Reed 1971. Fruit (inset, upper right). From Institute of Food and Agricultural Sciences.

*Nelumbo lutea* (yellow)

*akkotorkv* (Creek), *aco:batabí* [*aco:bata:bí*, *co:batabí*] (Koasati)

alligator buttons (South Carolina); alligator peas (South Carolina);  
sacred-bean (Louisiana)

American nelumbo (Mississippi)

[big]-bonnet (Mississippi, Tennessee)

can-dock (Louisiana)

duck-acorn (Louisiana)

*graine à voler* (stealing seed, maybe a reference to the tendency to “steal” habitat and crowd out other aquatics; or maybe a food worth stealing, Louisiana); *vole* (thief, Louisiana)

*grand oval* (big oval [leaf], Louisiana)

great yellow water-lily (New York); yellow pondlily (Arkansas)

*jacquinot* (maybe based on Algonquian *yankapin*, Missouri)

knock-knocks (South Carolina)

*kat’ho’pe* (Atakapa)

[American] lotus (in use by 1584 in English for these aquatic plants, from Egyptian *lotos*; in modern Arabic *bashnyn abklyad*, white lotus or *nîlûfar*, for *N. nucifera*; see *Celtis*: Hackberry, for alternate etymology); *Lotosblume* (lotus flower, German); yellow lotus (Arkansas)

[lily, monaca, pond, rattle]-nut (Louisiana, Wisconsin)

*tethawe* (Omaha-Ponca); *tewape* (Dakota); *tse’-wa-the* (*tse’-wa*, bison, *the*, this, Osage); *tsherop* (Winnebago)

*tukawiu* (Pawnee)

*wampain* [*wankain*, *wonkapin*, *yankapin*, *yonkapin*] (related to *chinquapin*, the Powhatan name in Virginia, first recorded in 1624 by Capt. John Smith but applied to *Castanea*; Arkansas, Illinois, Indiana, Louisiana); *wagipin* (crooked potato, Potawatomi); water chinquapin; *yonkapin-bonnet* (akin to *yankapin* and *wampain*, Algonquian, Tennessee); yawk-nut (akin to *yonkapin*, Louisiana)

The American lotus was discovered late by European scientists. Maybe the plants have always been uncommon in the northern part of North America, or perhaps they were rare because the indigenous people had eaten almost all of them. William Bartram actually collected one of the first plants in the 1770s; his collection forms the basis of the name *Nelumbo lutea*. That name was finally published in 1799 when C.L.von Willdenow created it as he revised Linnaeus’s *Species Plantarum*.

However, it may be that visitors to the New World thought they were seeing a plant they had known since the 1600s or perhaps earlier. The Asian species had been known in Europe since at least the time of Rheede’s *Hortus Indicus Malabaricus* in 1667–1703. Linnaeus had studied living plants for his *Hortus Cliffortianus* of 1738 and herbarium material for his *Flora Zeylanica* of 1747.

Bartram ([1791] 1958), for example, noted water lilies from Alabama, Florida, New Jersey, and North Carolina. He called them *Nymphaea nelumbo*, the name that Linnaeus had applied to the Indian water lotus in 1753.

Bartram ([1791] 1958) provided one of the first accounts of personal experience eating the seeds of these New World aquatic herbs. He wrote: “The seed vessel when ripe, is perforated, each cell containing an oval osseous gland or nut, of the size of a filbert; when they are fully grown, before they become quite hard, they are sweet and pleasant eating, and taste like chestnuts: I have fed freely on them without any injury, but found them laxative.”

Rafinesque wrote in 1817 that the roots were also eaten by indigenous people, but said little more than that they had to be prepared first (Hedrick 1919). Thomas Nuttall gave perhaps the first details about indigenous people using *Nelumbo*. In 1821, he wrote of the

Quapaw in Arkansas: “This morning I observed the wife of the chief, preparing for her family a breakfast from the nuts of the *Cyamus* (or *Nelumbo*). They are first steeped in water, and parched in sand, to extricate the kernels, which are afterwards mixed with fat, and made into a palatable soup. The tubers of the root, somewhat resembling potatoes or sweet potatoes, when well-boiled, are but little inferior to a farinaceous potato” (Nuttall in Coffey 1993). In 1837, Nuttall wrote of the Osage that *N. lutea* “is everywhere made use of by the natives, who collect both the nuts and roots” (Gilmore 1919).

Most of the recorded uses are as food. Various parts were used by the tribes and required distinctive preparation. Seeds were used as food by at least the Comanche, Creek, Dakota, Meskwaki, Ojibwa, Omaha, Osage, Oto, Pawnee, Ponca, Potawatomi, Quapaw, Seminoles and Winnebago (Gilmore 1919, Smith 1933, Fernald et al. 1958, Moerman 1998). Roots were eaten by the Dakota, Huron, Ojibwa, Omaha, Osage, Oto, Pawnee, Ponca, Potawatomi, Quapaw, Seminoles, and Winnebago (Gilmore 1919, Smith 1933, Fernald et al. 1958, Kindscher 1987, Moerman 1998, Snow and Stans 2001). Young leafstalks and unrolling leaves were used by some as a potherb (Fernald et al. 1958). Perhaps that is what Moerman (1998) meant when he wrote about “terminal shoots cut crosswise, strung on string, and dried for winter use” by the Meskwaki. However, the more widespread use, as among the Ojibwa, was to cut the rhizomes and store them for winter (Moerman 1998). The Missouri River people peeled and then cut tubers into pieces about an inch long and dried them for winter (Gilmore 1919).

The Dakota, Omaha, Pawnee, Ponca, and Winnebago attributed mystical powers to *Nelumbo* (Gilmore 1919). The reason for that is not given, but they held that tubers collected by a tall person would be long, while those gathered by someone short would be short. Perhaps that same attitude led to people using *Nelumbo* as medicine. Huron Smith wrote in 1933 that the Potawatomi used the roots, either fresh or dried, as a poultice for many “inflammatory problems” (Smith 1933). The same or a different view might have been the case when physician Cadwallader Golden told Peter Kalm in 1751 that the “Indians [probably Iroquois] use the roots” as a preventative for scurvy (Vogel 1970). Although Colden called the plants “a *Nymphaea*,” he may have meant the species. It could just as easily have been a *Nymphaea*, or even both genera, as either would serve the purpose.

Alice Snow had only heard that the green part of the seed (embryo?) had been made into a remedy to treat whooping cough (Snow and Stans 2001). She noted, however, that the seeds (*aktvpehv*, *ak*, in water, *tvph*, flat) were still eaten when they could be found. Snow observed, “There aren’t many of these plants any more because the white people take them out by the trailer full and take them up north and sell them. They use them for flower arrangements” (Snow and Stans 2001).

### *Nicotiana*

(Linnaeus named tobacco after the French diplomat Jean Nicot, 1530–1600, ambassador to Portugal in 1560, who promoted *N. tabacum* to the Portuguese and French courts; Nicot considered the plants of great medicinal value)

***Nicotiana rustica*.** From Britton and Brown 1898.

*Nicotiana rustica* (of the country)

*Nicotiana tabacum* (Taino name for rolled leaves of the plant used for smoking)

*aka* (Sumu, Nicaragua)

*akomî* [akahke] (tobacco, Mikasuki); *hece* [héce, hici] (tobacco, Muskogee); *hini* (Timucua; Crawford 1988 gave *epa* as “use tobacco,” in Timucua, but Gatschet 1877–1880 gave *hini*); *hisi* [ahisi] tobacco, Alabama); *hitci* [ahecha, heche, hitche] (said to mean “finding,” because that was the warrior’s name given to this powerful plant after it was discovered, cf. Swanton 1929; however, that derivation is doubtful, Creek); *hici pvkpvki* [hitci pakpaki] (*hici*, tobacco, *pvkpvki*, blossom, Creek; William Bartram was called *Puc Puggy* [*pvkpvki*, blossom] because he hunted flowers, cf. Bartram [1791] 1958; *Hici pvkpvki*, mentioned in the Creek “Emergence and Migration” story recounted in 1735 by *Chekilli*, cf. Lankford 1987; also in the Creek “Origin of Tobacco” story as “the greatest medicine there is,” cf. Swanton 1929; probably *N. rustica* although Swanton thought it might be *Lobelia*); *hitd atculi pakpaki* [itch-au-chu-le-pucpug-gee, eschalapootche, hid lapucki] (*hici*, tobacco, *vcule*, old man, *pvkpvke*, blossom; often “old man’s tobacco” or “blossom of the ancient people’s tobacco,” *N. rustica*, Creek, Muskogee, cf. Howard 1984)

*chandi* [tchondee] (used for *N. quadrivalvis* by Gilmore 1919, but no distinction made when *N. tabacum* became available, Dakota, cf. Catlin [1844] 1973); *noŋ-ni’-hi* [no-ne-aw, no-ní-hi] (*noŋ-ni’*, tobacco, *hi*, plant, Osage; archaic for any smoking material)

*charhû* [tcarhu, jarhooh] (fire to hold in the mouth, Tuscarora); *tsa’lu* [tsalu, tsáru, tso-la, szólaw, jola] (Cherokee)

*chomak* (Chickasaw); *hakchomma* (*hakcho*, tobacco, *homma*, red, Alabama); *hakchuma* [achumon] (Choctaw; probably from two words as in Alabama); *hakcommi* (Koasati)

*i’pa* (Catawba)

- i'tei* [i] (Yuchi)  
*iste'waw* (Plains Cree); *se'ma* (Potawatomi); *theyamah* (Shawnee, fide Edgar 1891)  
*iúri* (Garífuna, Nicaragua; cf. Coe and Anderson 1996)  
*kschátey* (Delaware)  
*kuutz* [cutz, k'utz] (Maya)  
*lapscon* (Arikara, cf. Catlin [1844] 1973)  
*mannah sha* (Mandan, cf. Catlin [1844] 1973)  
*ojenqua* (Onondaga)  
*petume* [petum, petema, petima] (from *pe'tim*, Tupi, Brazil)  
*pistacan* (Blackfoot, cf. Catlin [1844] 1973)  
*punche* [punchi] (New Mexico; cf. White 1941, 1942, Curtin 1947, Ford 1975, Cobos 1983, Howard 1984)  
*tac* (Ofo)  
 tobacco [tobaco, tobago, topaco] (to the Taino of the Caribbean, *tabaco* meant what we today call a cigar; “tobacco” was applied after the plant was introduced to Europe); *pyé tabak* (country tobacco, Haiti); *tabac* [tabak] (France, Haiti); *tabac mannoque* (*manoque* is from *manoca*, a fistful, and specifically refers to a bundle of leaves tied together at the base, using one of the leafstems, Haiti); *tabacco* (Italian); *tabaco* (Puerto Rico); *tabaco de olor* (fragrant tobacco, Dominican Republic), *Tabak* (German); *tombaca* [tobac] (Gaelic)  
*tsit* [tsigg] (Atakapa)  
*twahko* [twahku] (Miskito, Nicaragua); *wì'ru* (Paya, Honduras)  
*uppówoc* (they puff it, Carolina Algonquian, North Carolina); *vhpooc* [ahpooc, apookan, apooke, pooc, uhpoocan, upooc] (*N. rustica*; Powhatan, Virginia; Strachey 1612)  
*yani'* (Biloxi)  
*yetl* (Náhuatl, Mexico); *picietl* [pecielt] (from *piciliui*, reduce in size, yetl, tobacco; *N. rustica*, Náhuatl, Mexico)  
*zèb a la rên* (kidney herb, Haiti); *herbe à la reine*, queen's herb; a mistake for *zèb a la rên*?)

My introduction to tobacco came early because my father and grandfather smoked, but my most vivid early recollection is about the plant as medicine. When I was still too young to be in school, I developed a terrible earache. We lived outside the city limits, and that was before there were telephones to summon a physician. I remember lying on the couch sobbing from the painful throbbing. My father lit up a cigarette, squatted beside me, and gently blew smoke into my ear. Almost immediately the pain lessened. A few more puffs, and the aching was gone. I was greatly relieved, and can easily understand why early Europeans like Jean Nicot considered the weed medicinal.

There has been confusion about the identity of tobacco and the Taino name for it since Columbus first recorded finding the plant in the Caribbean. Part of the problem is that he found Taino people carrying “a half burnt weed in their hands, the herbs for smoking which they are in the habit of using” (Jane and Skelton 1960) and elsewhere noted they called it *cojiba* [cohiba]. Coll y Toste (1972) emphasized that the *cojiba* was the plant,

and the rolled leaves used for smoking were *tobaco*. In 1498, the Spanish wrote that the Taino called one island *tobaco*, although we now call it Tobago (Millspaugh 1892, Coll y Toste 1972). Spaniards were using tobacco in Yucatan by 1520, and Hernando de Toledo introduced it from there to Spain in 1559 (Millspaugh 1892). Columbus had probably already taken it back to Spain. It was being grown at Angoulême in France in 1556 (Hawkes 1998), before Nicot is supposed to have introduced it to the Portuguese and French courts.

It was Bartolome Las Casas in 1552 who, after Columbus, first gave the definition of *tobaco* as what we now call a cigar (from Spanish *cigarra*, the insect cicada, because of similarity of the rolled tobacco leaves to the insect's body; in use by 1730). At least Nicholas Monardes used the modern concept of *tobaco* in 1569 and illustrated *N. tabacum* (Frampton [1577] 1925). Rembert Dodoens had illustrated *N. rustica* in 1554, even though he called it "yellow henbane" (Goodspeed 1954). Sir Francis Drake and Sir Walter Raleigh found *N. rustica* being used by Canadian tribes and brought it to England in 1586 (Millspaugh 1983, Mabberley 1997).

There are 67 *Nicotiana* species in the Americas, the South Pacific, and Australia, with 7 or so used by indigenous North Americans (Goodspeed 1954, Mabberley 1997, Moerman 1998). We really do not know which tobacco Columbus found in use on Hispaniola (Sauer 1969), but the assumption is that it was *N. tabacum*. That species seems to have been confined to the Caribbean or nearby tropical mainland, and John Rolfe introduced *N. tabacum* from the West Indies into Virginia in 1610 or 1611 (Winter 2000). In doing so, Rolfe launched the basis of plantation life that still dominates the agricultural economy of the southeastern United States (Vogel 1970). *Nicotiana rustica* was cultivated from Peru to Canada, and some sources call it "Aztec tobacco" (e.g., Lewis and Elvin-Lewis 1977).

Because the de Soto narratives did not mention tobacco, Swanton (1946) concluded that it "had not attained the social significance it enjoyed in the seventeenth and eighteenth centuries." However, there is another interpretation. Since at least the 16th and 17th centuries it was a universal custom to smoke in friendly situations (Winter 2000), so there is no reason to expect the de Soto narratives to comment on tobacco. De Soto and his men ransacked every village they found, so the pipe certainly would not have been proffered.

Jacques Le Moyne, writing of the French Huguenot colony in Florida in 1564–1565 said, "They have a certain plant [*hini*], which the Brazilians call *petum* (*petun*), and the Spaniards *tapaco*. The leaves of this, carefully dried, they place in the wider part of a pipe; and setting them on fire, and putting the other end in their mouths, they inhale the smoke so strongly, that it comes out their mouths and noses, and operates powerfully to expel the humors" (Swanton 1946).

Barlowe reported tobacco growing along with corn in the fields of the Algonquians of North Carolina (Swanton 1946) in 1584. Similarly, Harriot ([1590] 1972) wrote at length about tobacco among the same people, recording the importance the plants already had throughout the southeast: "This *Uppowoc* is of so precious estimation amongst them, that they thinke their gods are maruelously delighted therewith: Whereupon sometimes they make hallowed fires & cast some of the powder therein for a sacrifice: being in a storm vppon the waters, to pacific theyr gods, they cast some vp into the aire and into the water: so a weare [weir] for fish being newly set vp, they cast some into the aire; also

after an escape of danger, they cast some into the aire likewise: but all done with strange gestures, stamping, and sometimes dauncing, clapping of hands, holding vp of hands, & staring vp into the heavens, vttering therewithal and chattering strange words & noises.”

In 1612, Strachey recorded the Powhatan name tobacco and several associated words. These Virginia people called the pipe *apokan* [*yppocane*, *vhpoocan*] (Harrington 1955), which has been transcribed phonetically as *ohpokan* by Siebert (1975), who also gave cognates for the word “tobacco pipe.” These related Algonquian words for “tobacco pipe,” and hence tobacco, are Cree (*ospwakan*), Delaware (*hopékan*), Fox (*ahwakana*) Menomini (*ohpuakan*), Miami (*pwakana*) and Ojibwa (*oppwakan*). The Powhatan called the tobacco pouch or bag a *vtmahcoih*.

Le Page Du Pratz recorded in 1758 that the tribes of the lower Mississippi used the calumet “in their treaties of peace and in their embassages, the principal usage of which is that the deputies of the two nations smoke it [tobacco] together” (Swanton 1946). He further commented that the *machonchchi* (*basho'nkchi*, the sumac that bears the purple bud, Mobilian or Choctaw) was mixed with the tobacco, “because in smoking they do not care to have the tobacco so strong” (Du Pratz in Swanton 1946).

The Creeks continued using *N. rustica* in medicines, in busk preparations, and as an offering in post holes where new cabins were erected in a “Square Ground” (Swanton 1946). Similarly, the Chickasaw were using it for those purposes in 1775 (Adair in Swanton 1946). Romans ([1775] 1961), however, found the Choctaw raising “some tobacco, and [they] even sell some to the traders, but when they use it for smoking they mix it” with sumac (*Rhus glabra*) and sweetgum (*Liquidambar styraciflua*).

A Creek name that probably refers to the old tobacco, *hid pvkpvki*, was recorded in a 1735 legend (Lankford 1987). Indeed, *N. rustica* was incorporated into indigenous stories by the Cherokee, Creeks, Hitichiti, and Yuchi. The Creeks, Hitichiti, and Yuchi share a legend, although the Yuchi are linguistically isolated (Swanton 1929, Jackson 2003). Here is a synopsis of the Yuchi version (Lankford 1987):

A man and woman went into the woods and had intercourse, and some semen fell on the ground. They went their own ways, but much later she again passed by the spot. A plant she had never seen before was growing there. Her lover did not know the plant, so she took her son to see it. It is implied that the son came from the earlier union, as he was “fatherless.” He was not familiar with the plant either, but decided to name it. He called it “*i*,” tobacco. He took some home, planted and grew it, experimented with it and showed the rest of his people how to grow and use it.

The legend among the Cherokee was considerably different. It concentrated on the beginning of the world when people and animals were the same (Mooney 1885–1886).

There was only one *tsa'lu* plant in the beginning and all came to that plant for their tobacco. Then the *Dagul'ku* geese stole it and carried it far to the south. People were suffering without it, and there was one woman who grew so thin and weak everyone thought she would die soon without tobacco.

Different animals tried to retrieve the plant. Both large and small were killed by the *Dagul'ku* before they could get the plant. Even the Mole tried, but he too was killed.

Finally, the Hummingbird offered to try. They said he was too small and should stay home. To prove his worth, he told them to point out a plant in the field and see how he would steal tobacco. They pointed out a plant, and suddenly there he was sitting on it. The next moment he was back beside them. No one had seen him move because he was so swift. "That is the way I'll do it," he said. So, they let him try.

He flew off and soon saw the tobacco. The *Dagul'ku* were all around it but he was so small and swift they did not see him. He darted down on the plant, snatched off the top with leaves and seeds, and was off before the *Dagul'ku* knew what had happened. Before he got home the old woman had fainted and they thought she was dead. But, he blew the smoke into her nostrils, and with a cry of "*Tsa'lul*" [tobacco] she opened her eyes and was alive again.

Presumably, the tobacco of the ancients was abandoned, or at least relegated to religious purposes, when the Caribbean *N. tabacum* became available. Swanton (1946) concluded that little time was devoted to cultivating *N. rustica*, in spite of Barlowe's and Romans's comments to the contrary and the clear indications in the legends that it was grown. Typically, *N. rustica* was "encouraged" but not always cultivated in the sense of ground tilling as for maize and beans (Winter 2001).

Although Small (1933) included *N. rustica* in the Florida flora, Wunderlin (1998) did not. Perhaps inclusion or exclusion is a question of what constitutes part of the "native" flora, because Chapman (1897) did not even discuss the genus in the southeastern United States. Kartesz (1994), like Small, also allows *N. rustica* among the indigenous North American plants. Asch and Asch (1985) have dated *N. rustica* in Illinois at A.D. 500–600, and in Iowa at A.D. 450–650, and Winter (2001) gives more information about it. Although it is clear that this tropical American species was cultivated by 2000 B.R at the latest and introduced by people into the eastern states (Fritz 2000b), it arrived long before the Europeans and therefore meets my criteria for inclusion.

### *Nuphar*

(Named by James Edward Smith, 1759–1828, using an Arabic name, *nīlūfar*)

*Nuphar lutea*. a. Habit, b. Petal and stamen detail, c. Seeds. Drawn by Regina O. Hughes. From Reed 1971.

*golfão amarelo* (yellow gulf; *golfão* is the augmentative from Greek *kolpos* and Latin *colup* or *golfu*, a gulf or large bay, presumably applied because these plants grow there, Portuguese)

*nenúfar amarillo* (yellow nuphar, Spanish); *nénuphar jaune* (yellow nuphar, French)

*ninfea gialla* (yellow nymph, Italian)

*Teichrose* (pond rose, German)

*Nuphar advena* (newly arrived, adventive, even though it is native)

*aco:batabí* [*aco:bata:bí*, *co:batabí*] (Koasati); *aktapi:horákko* [*aktapi:hoťákko*] (*okotaťketv*, floating, *ťákko* big, Creek); *okpalotcáyhi* (tall water floater, Mikasuki)

*çin'-mon-non-ta* (Osage; used in ceremonies)

*cyamus* (from Greek *kyamos*, a bean; Williams [1837] 1962 wrote that the fruit had edible seeds and that "Hogs will swim in the water to obtain the fruit")

*kítewi* (pine snake, name given because of the appearance of the roots when the water dries away and exposes them, Potawatomi)

*malangueta* (this odd name, resembles *malagueta* for chile)

mulefoot lily (Florida)

*pwakumosikum* (Cree)

spatterdock (USA)

*teghaizé* (Chipewyan, Canada); *teta* (Slave, Canada)  
 yellow pond-lily (Florida); yellow water chestnut (Florida, cf. Williams  
 [1837] 1962)

This was formerly considered part of Linnaeus's ([1753] 1957) *Nymphaea lutea*. In 1809, James Edward Smith, the British founder of the Linnaean Society of London, created *Nuphar* and put the species there. Wiersma and Hellquist (1994, 1997) argue that it should be a distinct species. There are now 16 species known from temperate and cold parts of the world, with 2 in Europe (Mabberley 1997).

Although the pollen was found in pre-Columbian Glades coprolites (Hogan 1978), no modern people in Florida seems to have used the plants. The Seminoles told Sturtevant (1955) that the plant was useless, but it has names in both Creek and Mikasuki. Perhaps it is not useless to all of them. Yanovsky (1936), King (1984), and Moerman (1998) found people throughout virtually its entire range using the plants for a variety of purposes.

### *Nymphaea*

(From Greek *nymphaia*, water nymphs)

***Nymphaea odorata*.** From Institute of  
 Food and Agricultural Sciences.

*bior-ròs* (pointed rose, Gaelic)

*duilleagh-bhàite bhàn* (leaf from down [below], Gaelic); *lìlì-bhàn*  
 (down [below] lily, Gaelic)

*golfão bronco* (white gulf; *golfão* is the augmentative from Greek *kolpos* and Latin *colup* or *golfu*, a gulf or large bay, presumably applied because these plants grow there, Portuguese)

*lotos* (Greek)

*nenúfar* (yellow nuphar, Spanish); *nénuphar* (nuphar, French); *nīlúfar* (Arabic); *ninfea* (Spanish); *ninfea bianca* (white nymph, Italian)

*Seerose* (ocean rose, German)

***Nymphaea odorata*** (fragrant, the flowers)

*a' yip te' xlk ta' l'kop* (*a yip*, marsh, *te' xlk*, flower, *ta' l'kop*, blue, Atakapa)

*aco:batabi* [*aco:bata:bi*, *co:batabi*] (Koasati); *akkotórkv* (maybe from *okotafketv*, floating, Muskogee); *ayipifo pakaali* (*ayipi*, lake, *fa-o*, place, *pakaali*, flower, Alabama); *okifoopatka* (*oki*, water, *fa*, place, *oo-*, within, *pat(àa)ka*, to be put, Alabama); *oktaak okpalli* [*okpal*] (*oktaak*, prairie, *okpalli*, to float, Chickasaw); *ue-ak-tv'phe* (from *uewv* or *oke*, water, *tv'phe*, broad, Muskogee)

alligator-blankets [-bonnets] (Louisiana, South Carolina)

beaver-root (Newfoundland)

*chumbacua* [*chumbagua*, *chumbahua*] (Tarascan, Michoacán)

cow-cabbage (Texas); water-cabbage [-nymph, -queen] (Texas)

fairy-boats (Texas)

*flor de agua* (water flower, Panama)

*guia benne* [*guia beñe*] (*guia*, flower, *benne*, mud, Zapotec, Oaxaca)

*lampazo* (spot-light, Nuevo León)

[pond, toad, water, white water]-lily [waterlily]

*locasolkahiliswa* (*loca*, turtle, *sulka*, many, *hiliswa*, medicine, Creek);

*yokcacó:kayikci* (many turtle medicine, Mikasuki)

*nabagúck* (Potawatomi); *pok-shicken-i-uck* (Ottawa tribe of Ojibwa);

*wabi'nabagac* (white water lily, Potawatomi)

*néufar blanc* (white nuphar, Quebec)

*ova de galleta* (cracker's egg)

*pagayeur* (paddler, Louisiana, Quebec)

*se'np'odal-e'* [*saiñ-po-dal*] (Kiowa)

star lotus (South Carolina)

*tapalule chobe* (*chobe*, big, Mikasuki)

In 1791, Dr. Cadwallader Colden wrote to Peter Kalm that indigenous people did not get scurvy like the Europeans because they ate the roots of a *Nymphaea* (Vogel 1970). Possibly that was *N. odorata* because Huron Smith found the Ojibwa cooking the flowerbuds of that species for food (Yanovsky 1936). Millspaugh (1892) noted a number of medical uses learned from indigenous people, and King (1984) and Moerman (1998) record the Meskwaki, Micmac, Ojibwa, Okanagan-Coville, Penobscot, and Potawatomi using *Nymphaea* for medicines and food.

In Florida, Hogan (1978) found lilies among preColumbian Glades people. Williams ([1837] 1962) recorded that the Seminoles used the root to cure “felons” (a small abscess or boil; apparently based on Latin *ulceribus*; used for these sores by about A.D. 1116).

Sturtevant (1955) was told that there were two kinds, but he was given a single name, *yokcacó: kayikcî*, for it. At the time they used them for “Turtle Sickness,” “Chronic Sickness,” and in childbirth. Bennett (1997) was told that a root infusion in winter was used to treat diarrhea.

No information has been found on similar uses among indigenous Americans, but *N. alba* in Scotland is *cairt-locha* (lake-bark, Gaelic) or *rabhagach* (joker, Gaelic), and juice from its roots was boiled as a mordant for dyeing wool (Dwelly 1933). Possibly New World species were used in a similar way.

### *Nymphoides*

(Named by Jean François Séguier, 1703–1784, with Greek *nymphaia*, water nymphs, -*oides*, meaning resembling *Nymphaea*)

***Nymphoides aquatica*.** a. Habit, b. Corolla spread open, c. Capsule.  
*Drawn by Vivian Frazier. From Correll and Correll 1972.*

***Nymphoides aquatica*** (growing in water)

*aktvpehv* [vktvpehv] (water floater, from *okotafketv*, floating, Creek);  
*okpalóhli* [akpolohlooche] (water floater, Mikasuki)

[big] floating-heart (Florida)

*icha:swalópi ahá:ka* (*echaswv*, manatee, *lope*, liver, *vhvka*, roots, Creek); *posá:flô:pâ:bî* (manatee liver replica, Mikasuki); *posá:flô:pí* (manatee liver, Mikasuki)

Linnaeus put *Nymphoides* (as a species) in the genus *Menyanthes*, which was an improvement over the Gentianaceae and other families that later students used. However, it was only a year later, in 1754, when Jean François Séguier created the genus *Nymphoides*. There are 20 species in the genus, widespread in wetlands, with the only *N. peltata* in Europe (Mabberley 1997). Some have edible tubers, and others have medicinal seeds.

Sturtevant (1955) found the Big Cypress Seminoles using these herbs for “Turtle Sickness” (trembling, shortness of breath, cough), “Chronic Sickness,” and in childbirth. Snow and Stans (2001) applied one of the same names but gave no remedies.

This species occurs in Virginia and the Carolinas to Florida. There are several other species nearby with uses. In Cuba and Puerto Rico, *N. indica* is the *trebol de agua* (water clover), and is used against stomach problems, as an antiseptic, a vermifuge, and for fevers (Roig 1945). It is also known as *tréfle d'eau* (water clover, French Antilles) and water snowflake (Jamaica).

### *Nyssa*

(From Greek *nyssō*, to pierce or prick; the name was taken from *Nysa* or *Nyssa* because she was one of the water nymphs; the only species Linnaeus knew, *N. aquatica*, grows in wetlands, so its name is a double mnemonic)

*Nyssa aquatica*. Drawn by Vivian Frazier. From Correll and Correll 1972.

*Nyssa aquatica* (growing in wetlands, aquatic)  
bottle-arsed tupelo (so called by Romans [1775] 1961)

Chickasawatchie whitewood (*Chickasawatchie* or *Chickasaw-hatchee*, meaning “Chickasaw river”)

cottonwood [bastard, gum] (could this comparison be made because their foul-tasting fruits turn the mouth to cotton?)

gum [black, bowl, cotton, gray, ladle, papaw, sap, sour, swamp, water, white, yellow] (“gum” first used by Chaucer in 1385 in the sense of a viscid plant secretion; differs from a resin in that it is soluble in both hot and cold water. Derived from Old French *gomme*, cognates include Portuguese and Spanish *goma*, Italian *gomma*, Latin *gumma*. First applied as an abbreviation of “gum-tree” in 1802, and then in 1817 it was being used to mean a hive for bees cut from a tree stem section. Perhaps that last name came into being because preference was given to hollow *Nyssa* and *Liquidambar* for making hives.)

hornbeam (classical name of *Carpinus*; reference here obscure)

*hush apa* (“to kill birds,” so named because birds eat the berries and are more easily killed for food, Choctaw)

*lobonó* (Koasati)

*okifa itto* (*oke*, water, *fa*, place, *itto*, tree, Alabama)

[wild] olive-tree [olivetree] (an allusion to the resemblance of the fruit to an olive, *Olea europaea*; a comparison that was made by Mark Catesby in 1730)

pepperidge (derivation obscure, but from “pipperidge”; first used by 1538 in Europe for the barberry, *Berberis*; by the 1820s, in Suffolk, England and in New England the word was changed to “pepperidge” or “pepprage”; it retained the reference to barberry in the Old World, but was reapplied to *Nyssa* in the Americas)

poplar [bay, hickory, swamp] (allusion obscure, cf. *Populus*)

[big, gum, large, swamp, rootwood, water] tupelo [tupeloo, tupola, tupolo, tupelow] (from *eto*, tree, *opelwv*, swamp, Muskogee; used in print by 1730; one of the first to use it was Mark Catesby; “tupelo” is the “preferred” common name)

*yassaakohatka* [*yassàakohatka*] (*yassaako*, sweet gum, *hatka*, white, Alabama)

*Nyssa ogeeche* (the *Ogeeche* were the Yuchi living on the Georgia and South Carolina border near the time of Bartram’s visit in 1773; maybe from the Hitichiti word *Ochese*, “people of another language”)

gopher plum (“gopher,” as *gaufre*, honeycomb, was applied to burrowing animals by the French because their dens are like “honeycombs.” “Gopher” was the name already established for the tortoise that Linnaeus called *Gopherus polyphemus* in 1759. Perhaps applied because the trees are often hollowed, or because of some perceived connection to the tree of the Bible, Hebrew *gopher*, whose wood made the ark.)

limetree [wild] (name used by John Bartram in 1765)

Ogeechee [Ogeche, Ogeeche, Ogeeche] lime (found by John and William Bartram in October 1765, but the first published record is Bartram [1791] 1958; fruits were used as substitutes for lime, *Citrus aurantiaca*, in 1765 in the region of southern Georgia and northern Florida where the species grows)

Ogeechee tupelo (the “preferred” common name) [gum, lone, sour, white] tupelo (from *eto*, tree, *opelwv*, swamp, Muskogee)

***Nyssa sylvatica*** (of the woods)

*antudayudi*’ (Biloxi)

bee gum (bee-hives or “gums” made from stem sections; in use by 1817); beetle-bung (surely a corruption of “bee gum”); [plain, quartered] black gum [blackgum] (this is the “preferred” common name); bowl gum (stems used to make bowls); cotton-gum [cotton gum] (an obscure allusion to cottonwood, *Populus*); gum (see under *N. aquatica*); sour gum (already in use in the southeast by the time of William Bartram’s visit, 1773–1774); yellow gum [yellow gumtree]

black tupelo; *tupelo negro* (black gum, Spanish); *tupelo noir* (black gum, French); tupelo (see also *N. aquatica*); moeras tupelo (modifier obscure); [*svart*, *zwarte*] tupelo (surely modifiers are German *schwarz*, or Dutch *zwart*, black)

*cabo de luc* (maybe “Cape Lucas,” Mexico)

*chiste* (a sweet also known as *alfajor*, Mexico)

*helukwv-vpe* [*helocoppe*] (*helukwv*, black gum, *vpe*, stem, Muskogee; compare with *Liquidambar* and *Eugenia* names); *helúk-lv’ste* (*helukwv*, black gum, *lv’ste*, black, Muskogee); *hikahí* (Koasati)

hornbeam [hornbine, hornpine, hornpipe] (classical name of *Carpinus*; application here obscure, especially since the wood of *Nyssa* is soft)

*iti ani* [*itani*] (*iti*, tree, *ani*, berry, Choctaw)

*kosapa* [*kosapi*, *kosapo*] (Alabama)

*lent tachkw’ákan* [*lenni tachquohacan*] (grindingdevice [mortar] making-tree, Delaware)

*nyssa sylvestre* (translation of scientific name into French, Quebec)

*palo de papaxi* (the name seems to compare *Nyssa* with *Randia*, the *papache*, Mexico)

pepperidge (see under *N. aquatica*)

*petcui* (Mexico)

snag-tree (“snag” probably of Scandinavian origin, cf. Norwegian dialectic *snag*, sharp point, stump; akin to Icelandic *snagi*, peg; used for “stump” in English by 1577; also in dialectic the sloe, *Prunus spinosa*, by 1587; perhaps an allusion to the fruits)

stinkwood (since 1300, “stink” has meant an offensive smell; application obscure)

*tetzicohuitl* (*tetzico*, restrains, *cuahuitl*, tree, Náhuatl, Mexico)

*udalana* (Cherokee)

wild pear-tree (an allusion to the fruits)

*yap be?be’?* (tree immovable, Catawba)

John W. Swanton (1946) created the single most valuable resource on how indigenous people in the southeastern United States lived from the time of European contact until the

early 1900s. However, that book is one of the most maddening in existence because of its inconsistencies and disorganization.

One of the problems with the book surfaces with consideration of *Nyssa*. Swanton purports to give historical synopses of tribes and translations of tribal names (pp. 81–219). However, nowhere in those lists does he mention the Ogeeche or any variant spellings of it. He discusses the Ogeeche elsewhere in the text, and shows where they lived on the maps, but there is no hint of them in pages 81–219.

Regardless, by making comparisons within the text it appears that *Ogeeche* may be the same as *Ochese*. Earlier (Swanton (1939) said that *Ochese* was a Hitichiti word with the same meaning as *celokke* [*chilokee*] in Muskogee, or “people of a different language” (Martin and Mauldin 2000). That tribal name is the source of Florida’s third *Nyssa* species name and was applied by William Bartram during his excursion through the South in the 1770s.

Near Fort Barrington along the Altamaha River in Georgia, Bartram hired a Creek to take him in a boat to see the plants now called *N. ogeeche*. He wrote: “They grow in the water, near the shore. There is no tree that exhibits a more desirable appearance than this, in the autumn, when their fruit is ripe, and the tree divested of its leaves; for then they look as red as scarlet, with their fruit, which is of that colour also. It is of the shape, but larger than the olive, containing an agreeable acid juice. The leaves are oblong lanceolate and entire, somewhat hoary underneath, their upper surfaces of a full green, and shining; the petioles short, pedunculis multifloris. The most northern settlement of this tree, yet known, is on Great Ogeeche, where they are called Ogeeche limes, from their acid fruit being about the size of limes, and their being sometimes used in their stead.” The place he refers to as the “Great Ogeeche,” the Ogeechee River, is one of the longest in Georgia and flows southeast between the Savannah and Altamaha Rivers.

My own impression of these trees was not much like Bartram’s. Those I saw in Apalachicola National Forest were scrawny little things compared to their two cousins in the eastern states. Admittedly, I saw them only in leaf and flower and not at their peak of fruit as did Bartram. Still, I am not the only one who was not as taken with them as he. In 1824, South Carolina professor Stephen Elliott wrote of “the pleasant acid of its fruit,” but added, “its last flavour is austere” (Elliott in Fernald et al. 1958). On the other hand, Small (1933) considered a beverage of the fruits good.

Even Elliott’s comment would be a compliment to the fruits of *N. aquatica*. Fernald et al. (1958) described them as having “disagreeably tasting fruits as large as a small olive.” However, they say the fruits of the northern variations of *N. sylvatica* “are bluish stone-fruits with a very thin pulp, but sharply acid and pleasant to roll in the mouth in autumn and winter.” Perhaps we humans simply do not appreciate what constitutes “good” fruits, as these are among the most desirable of snacks for wood ducks (*Aix sponsa*). I have fond memories of watching these dazzlingly colored waterfowl feed on *N. aquatica* fruits.

The primary use of *Nyssa* among indigenous people seems to have been as a dye or medicine. The Choctaw burned the bark and mixed in red oak ash to make a red dye (Bushnell 1909, 1917). Since the oak alone would have given a red color, perhaps the *Nyssa* was added as a mordant. The Alabama, Creek, Houma, and Koasati made medicines from *Nyssa*, at least *N. sylvatica*, and possibly other species. The Alabama used the plants to treat “cancer” (Hocking 1997). The Creeks made a preparation of the bark and chips to treat tuberculosis (Swanton 1928a, Taylor 1940). The Houma made a

root or bark decoction to expel intestinal worms (Speck 1941). The Koasati applied a bark decoction to gunshot wounds and drank some to help the healing (Taylor 1940).

The Cherokee used *N. sylvatica* in most of the same ways as their neighbors did, plus some unique applications. They too expelled worms with it, but they also used medicine made from it to stop diarrhea, as an emetic, during childbirth, and for urinary infections (Taylor 1940, Hamel and Chiltoskey 1975). The Cherokees also dripped ooze from the roots into the eyes to help them heal (Hamel and Chiltoskey 1975).

Swanton (1946) recorded indigenous southeastern people using *Nyssa* wood in making drums (species not indicated, perhaps all). Farther north, the Ojibwa used the wood of *N. sylvatica* to make awl handles, mauls, and war clubs because it does not split or check (Moerman 1998). Wood has been used in more recent years as veneer, plywood, railroad cross ties, boxes, cooperage, pulp, woodenware, hubs, wharf piles, handles, and planing-mill products (Vines 1977). Twigs were made into chewsticks for cleaning the teeth and into snuff dipsticks for making the teeth dirty (Hocking 1997).

Settlers also found inventive ways to utilize *N. aquatica*. Wood from those trees was made into boxes, woodenware, and fruit crates; the light, spongy roots were used to make net floats and corks (Vines 1977). Uses hidden within common names, but rarely recorded elsewhere, are to make bowls and ladles. It is also called “sap gum,” so perhaps sugar was extracted from it.

During the Civil War, Porcher (1863) recorded: “The roots are white, spongy, and light, and are sometimes used in the Confederate States as a substitute for cork.... The genus exhibits a constant peculiarity of organization (‘the fibres are united in bundles and interwoven like a braided cord’), hence the wood is extremely difficult to split, unless cut into billets—much used for hubs of wheels; also preferred for the sideboards of carts.... Trays, bowls, dippers, mortars, and other utensils are manufactured from it. ... Mr. W. Gilmore Simms suggests to me the use of the tupelo, on account of its lightness, for making cartridge-boxes.” Porcher also writes at length about the wood being made into *sabots*, wooden shoes worn by slaves.

One of the strangest applications for *Nyssa* wood is construction of a “tupelo-tent,” a surgical “tent” made from the spongy wood of the roots. Perhaps that too came about during the Civil War. No explanation has been found, but these “tents” were perhaps like the towel covering used in modern surgery to keep areas surrounding the incision covered—and to soak up excess fluids. Hocking (1997) also compares the use to “Laminaria pegs,” i.e., as “tents” and dilating bougies for distending body cavities during surgery. The pegs also have been used to induce abortion.

The first American use of the name “pepperidge” was in a literary and not a scientific context. None other than James Fenimore Cooper, in his 1826 book *The Last of the Mohicans*, referred to a “trencher, neatly carved from the knot of a pepperage.” That was probably a passage that Cooper never expected anyone to remember, but it provided ethnobotanical information on a tribe that is not recorded elsewhere.

# O

## *Obolaria*

(From Greek *obolos*, Latin *obolus*, a small Greek coin, referring to the thick rounded leaves)

***Obolaria virginica*.** From Britton and Brown 1897.

***Obolaria virginica*** (of Virginia)

*klotchoachokama* (*achokma*, good, Choctaw)

[Virginia] pennywort

*Obolaria* is a small mycotrophic plant with the single species endemic to eastern North America (Mabberley 1997). The first record of this herb in Europe was published by Robert Morrison in 1680 about a cultivated plant in London. He, Leonard Plukenet, and John Ray called the plants *Orobanche virginiana*, *radice coralloide summo caule foliis subrotundis* (*Orobanche* from Virginia, with roots like coral and stem having almost round leaves). Gronovius in the *Flora Virginica* of 1739–1743 called it *Obolaria*, and Linnaeus finalized the name as *O. virginica* in 1753.

Although formerly placed with *Orobanche*, these are relatives of gentians. This is another of the saprophytic members of that family (see also *Voyria*). We now know that the species grows from Florida to Texas, north to New Jersey and Pennsylvania, West Virginia, Ohio, Indiana, and southern Illinois (Fernald 1950, Mohlenbrock and Voight 1959, Correll and Johnston 1970).

The Cherokee made a medicine of these plants for colds, coughs, and colic, and used it as a diaphoretic (Hamel and Chiltowsky 1975). The Choctaw used the water from the boiled roots, mixed with boiled sweetgum roots, on cuts and bruises (Bushnell 1909).

*Ocotea*

(J.F.Aublet named these trees after a Carib Garipon word from French Guiana; the species they call *ojouhou-ha*, he rendered as *Ocotea guianensis*)

*Ocotea coriacea*. Drawn by  
P.N.Honychurch.

***Ocotea coriacea*** (leathery)

*aho:slâknî* [*ahilâkno:cî*] ([small] yellow tree, Mikasuki)

*avisillo* (little wasp, Puerto Rico)

bastard [black] torch (Bahamas)

*bois doux négresse* (sweet black wood, Guadeloupe)

*cabirma aromdtica* (aromatic *cabirma*, Taino word for some tree, Dominican Republic)

*Cap Henri* (a locality, Haiti)

cap-berry [capberry] sweetwood (Jamaica); rock sweetwood (Panama)

*cigua* [*sigua*] (laurel, Taino, Cuba, Puerto Rico, Panama); *cigua blanca* (white laurel, Dominican Republic)

*cip-che'* (*kip*, smooth or slick, *che'* tree, Maya, Campeche)

*cochoch-che'* [*hochokche, xhoch-che'*] (*koch*, something narrow, *hoch*, something hollow, *che* tree, Maya, Quintana Roo, Yucatán); *hoc-che'* (*hoc*, something hollow, *che'*, tree, Maya, Yucatán); *jobon-che* (*hobon*, hollow, *che'*, tree, Maya, Quintana Roo)

lancewood (a reference to leaf shape, Florida)

*laurel* (laurel, Mexico, Belize, Puerto Rico); *laurel avisillo* [*cigua*] (wasp laurel [laurel laurel], Puerto Rico); *laurel perdiz* (quail laurel, Dominican Republic); *laurel verde* (green laurel, Yucatán); *laurier* [*blanc*] ([white] laurel tree, Haiti); *laurier marbré* (marble laurel tree, Grenada)

*lebisa* (usually a name given a fish, *Dasybatus torregi*, Taino?, Cuba)

*palo de gas* (gas tree, Yucatán)

pepper cillament (pepper cinnamon, Virgin Islands)

*siguaraya* (Taino?, Cuba)

sweet torchwood (Bahamas); sweetwood (Jamaica, Belize, Dutch Antilles)

*tola:nocî* (*tola*, red bay, *noce*, milkweed, Creek)

People are told that one of the traits of tropical forest trees is that leaves of many species are similar. Indeed, one of the last species in the West Indian forests along the southeastern Florida coast that I learned to recognize was the lancewood. My students were similarly challenged by the species.

Unlike many members of the family, the foliage is not very aromatic. It requires a combination of leaf venation traits, bark comparisons, and considerable luck to distinguish the lancewood from the Guiana plum when they are neither flowering nor fruiting. Perhaps that same difficulty is part of the reason botanists have had such a hard time deciding on the proper name of these short-lived trees.

Discounting the placement of the species in *Laurus*, the discussion is whether the trees should be in *Nectandra* or *Ocotea*. *Nectandra* (from Greek *nektar*, nectar, plus *andros*, stamen) was described by Daniel Rolander (1725–1793) and Christian Friis Rottboell (1727–1797) in 1778. Three years earlier, Aublet had named *Ocotea* and used it for a French Guiana tree that the Garipon Caribs applied to drain tumors and swollen glands (Aublet 1775).

Olaf Swartz first described this species in 1788 and called it *Laurus coriacea*. Subsequently, it has been considered either a *Nectandra* or *Ocotea* (Chapman 1897, Sargent 1905, Britton and Millspaugh 1920, Small 1933, Long and Lakela 1971, Correll and Correll 1982, Rohwer 1993).

Historically, the only recorded use in Florida is among the Seminoles. Their warriors used the wood for bows (Sturtevant 1955).

Wood, with light brown sapwood and dark brown heartwood, has been used in carpentry, cabinetwork, for poles, and to make charcoal (Small 1933, Little and Wadsworth 1964, Liogier 1974). In Mexico, the trees are used for wood in Yucatan. However, the common Mayan names make me wonder how much they value them. No other uses have been found for *N. coriacea* although *N. rodiaei* (Greenheart) of South America is well known as a source of wood (Standley 1920–1926). Bark of that tree contains the alkaloids bebeerine, sipirine, and nectandrine, which are tonic, astringent, and a febrifuge like cinchona. Perhaps some of the same compounds are in other members of the genus.

### *Oenothera*

(Said to be based on *oinos*, wine, and *them*, catcher; a name used by Theophrastus, 372–287 B.C., for some Onagraceae; however, Pliny, A.D. 23–79, wrote, “*onothera, sive onear, hilaritatem afferens in vino*” [ass-catcher, or ass-hunter, a plant whose juice in wine causes happiness; or, as translated in 1601, “Oenothera, otherwise Onuris, an herb good also in wine to make the heart merry”])

*enagra* (from Latin *onager*, Greek *onagros*, the wild ass, *Equinus onager*, Italian); *onagre* (French); *hierba del asno* (ass herb, Spanish)

evening primrose (“primrose” from Latin *prima rosa*, the earliest rose, applied to *Primula* since 1400s; combined with “evening” since the 1760s because of the nocturnal flowers)

*Nachtkerze* [*Nachtkerz*] (night candle, German)

***Oenothera biennis*** (biennial, maturing in two seasons)

*canhlo'gan hu'nla* (rattle weed, Lakota)

coffee-plant (an infusion used as a drink in the harvest field, cf. Coffey 1993, North Carolina)

cure-all (used as a domestic medicine, cf. Coffey 1993, North Carolina)

evening [night] primrose [common, eveningprimrose] (because the flowers open in the evening and close in the morning; applied to these plants by the 1760s)

fever-plant (used as a diaphoretic in fevers, cf. Coffey 1993, Kansas)

[large] German rampion (“rampion” has been the name for bellflower, *Campanula rapunculoides*, since the 1760s; related to French *raiponce*, Italian *ramponzolo*, German *Rapunzel*, Kansas)

golden-candlestick (Kansas)

king's cure-all (South)

*nattlys* (night light, Norwegian)

night willow-herb (“willow-herb” has been applied to a variety of plants because their leaves resemble those of *Salix*; originally recorded in 1574 by Rembert Dodoens)

*owesa'wanakuk* (yellow top, Potawatomi)

scabbish [scabish, scabiose, scavey, scurvis] (Josselyn in 1638 thought it was confused with “scabious,” or *Knautia*, Maine, New Hampshire, Ontario, South Carolina)

speckled-John (Kansas)

tree primrose (used since 1638)

***Oenothera fnticosa*** (shrubby, a misnomer)

sundrops (used since the 1790s for any of the species whose flowers open when touched by the morning sunshine)

narrowleaf evening primrose [eveningprimrose]

wild beet (used as a potherb in West Virginia, Coffey 1993)

For some unexplained reason, Linnaeus told us that *Oenothera biennis* was introduced from Virginia into Europe in 1614. After that time, a number of herbalists and botanists commented on the plants. Caspar Bauhin commented on them in his *Pinax* of 1623. Gronovius included them in his *Flora Virginica* published between 1739 and 1743.

The perplexing thing about Linnaeus commenting that the plants were introduced from Virginia is that now some contend that *O. biennis* is not an American native. Both Clapham et al. (1987) and Mabberley (1997) say that it is native to the Old World.

In his wonderful way, Linnaeus created a Gordonian knot when he used the name *Oenothera*. There simply is no single translation for that word. Most people either avoid

the problem, as when Fernald (1950) wrote, "Name used by Theophrastus for a species of *Epilobium*" or simply "Greek, meaning wine-scented" (Munz 1973). However, as Coffey (1993) correctly points out, it can mean "wine-scenting," "wine-imbibing" (from *oinos*, wine, *them*, imbibing), "donkey-chase" or "ass-catcher" (if based on *onos*, donkey, *them*, hunt or chase). An enticing epilogue was added to the etymology in 1860 when Joseph E. Worcester's *A Dictionary of the English Language* recorded, "The roots of the species *Oenothera biennis* are eatable, and were formerly taken after dinner to flavor wine, as olives now are; hence the name *Oenothera*, or wine-trap." Porcher (1863) interpreted the history somewhat differently. He wrote, "The ancients thought the plant possessed the power of allaying intoxication and calming the most ferocious animals."

John Josselyn, writing in 1674, explained some of the common names in *An Account of Two Voyages to New-England Made During the Years 1638, 1663*. He wrote that it was the "yellow Lysimachus of Virginia," and that, because it has "the Flower yellow and like Primroses, [it is] therefore called Tree-Primrose." He went on to say that the English settlers in New England took it to be "scabious" (*Knautia arvensis*, *Dipsacaceae*) (Coffey 1993). Peter Kalm's observations made 75 years later support Josselyn's. While Kalm was in Montreal in 1749, he noted *O. biennis* in abundance in open woody hills and fallow fields. He wrote: "An old *Frenchman*, who accompanied me as I was collecting its seeds, could not sufficiently praise its properties of healing wounds. The leaves of the plant must be crushed, and then laid on the wounds" (Kalm [1753–1761] 1972). Perhaps Josselyn's and Kalm's informants did not know the proper scabious plant, and simply knew that *Knautia* was used to heal sores like the Tree-primrose.

During the 1800s, *O. biennis* was cultivated in English and German gardens for its edible roots (Hedrick 1919). However, the French looked askance at it as an edible and grew it only as a curiosity. During the 1860s, it was even sold by enterprising Americans to their gullible compatriots as "German Rampion."

Porcher (1863) wrote: "The root and herb have been employed in cutaneous diseases. Dr. Griffith has used it with success in tetter, applying the decoction to the affected part several times a day, and giving it internally at the same time. He has been successful with it in subsequent trials. The plant should be gathered about the flowering season. The young sprigs are mucilaginous, and can be eaten as salad.... Its roots have a nutty flavor, somewhat similar to those of rampion, and are used in Germany and some parts of France, stewed and raw, in salads, with mustard, oil, salt, and pepper, like common celery."

The Cherokee cooked and ate the leaves as greens and boiled the roots like potatoes (Hamel and Chiltoskey 1975, Moerman 1998). Otherwise, the eastern tribes used the herbs as medicine. The Cherokee took an infusion to treat obesity and to relieve piles (Hamel and Chiltoskey 1975). The Iroquois too used the plant to treat piles and boils (Moerman 1998). The Ojibwa put a poultice on bruises (Moerman 1998). The Potawatomi used the seeds for "medicine" (Smith 1933).

Scotia Pharmaceutical, Inc. in England discovered that *O. biennis* was rich in GLA (gamma-linolenic acid) compounds, which are important in the production of fatty acids and prostaglandins. It has been selling these oils in health-food stores for years, and Mabberley (1997) records that the company did a £36 million business in 1993. The company suggests that its product can alleviate, if not cure, a variety of diseases. Many

remain skeptical, and Mabberley (1997) noted that placebo tests were as effective as the GLA.

### ***Opuntia*: Prickly Pear**

(Philip Miller gave us the generic name *Opuntia*, taking it from Latin *herba opuntia*, from *Opus*, *Oputis*, a town of Locris in Greece; in Greek *Opous* or

*Opountos*; the Latin name was used by Theophrastus, 372–287 B.C., for some unknown plant, and Miller applied it to the New World cacti)

***Opuntia stricta* var. *dillenii*. a.**

Habit, b. Young joint, with leaves

remaining in areoles. c. Areole. d.

Glochid from areole. e. Flower, from

above, f. Flower, side view. g. Flower,

longitudinally dissected, h. Fruit, i.

Seed. Drawn by Priscilla Fawcett.

From Correll and Correll 1982.

In 1989, Carol Lippencott found the cactus moth (*Cactoblastis cactorum*) on the endangered semaphore cactus (*Opuntia corallicola*) in the lower Florida Keys (Habek and Bennett 1990). In March of 1992, we found the moth on the prickly pear cacti (*O. stricta* var. *dillenii*) at the Florida Atlantic University campus in Boca Raton more than

100 miles north of the Keys site. Cacti that had been almost 2 m tall (6 feet) in Boca Raton were eaten to the ground within less than a year.

Now the insects are found throughout the Florida peninsula and are spreading through native *Opuntia* farther north. As the moths spread, cattle ranchers' hopes that they will eliminate cacti from the state escalate along with their visions of increased profits. Biologists are terrified that the insects will continue around the Gulf of Mexico to eradicate the many *Opuntia* species that populate the Chihuahuan and Sonoran Deserts of the United States and Mexico. If they spread as feared, millions of people will be impoverished.

Several species of prickly pears are an essential part of the lives of people in Mexico and the southwestern United States. *Opuntia* have been used as food and medicines for thousands of years. The plants were so important to the Aztecs that they named cities for them (e.g., *Tenochtitlan*, place where nopal grows on rocks), and *Opuntia* now appears on the Mexican national flag.

Spaniards found *Opuntia* cacti on their first trips to the New World. Soon afterward, the indigenous names *nopal* and *tuna* became elements in the Spanish language. *Nopal* (the plant, from *nopalli*, Náhuatl) is applied to all of the flat pad cacti (*Opuntia*), although sometimes *Nopalea* is considered a distinct genus. *Tuna* (the plant and fruit) comes from Caribbean Taino language although it is superficially similar to *atún* (Spanish) and *thunnus* (Latin), which refer to the fish in the family Scombroideae. The importance of *Opuntia* in Mexico is partly indicated by their designation in various languages. They are *biichi* [bitzu] (*bi*, fruit, *ichi*, spiny, Zapotec), *câhâ* (fruit, Otomí), *xâthâ* (plant, Otomí), *nochtli* (fruit, Náhuatl), *pak'ak'* [*pacac*] (Huastec), *pak'an* (Maya), *pare* (Tarascan), *taat* (Mixe), and, in Cochimi, the single vowel "a." The Seri and Mayo do not have a generic name for prickly pears, but they use distinct names for each species (Felger and Moser 1985, Yetman and Van Devender 2001).

Europeans had never seen plants like prickly pears before arriving in the New World because the family Cactaceae was endemic here. Oviedo ([1526] 1969) conveys something of the astonishment they felt when he wrote: "There are some wild plants...called *Tunas*. And they grow on some very spiny thistles [*cardos*] and produce the fruit that is called *tunas*, that is similar to young figs [*brebas*] or figs [*higos*], being about the same size.... And within are very red and have small seeds like figs."

Eating the fruits produces effects that are surprising to novices. When they are in fruit around my home in Tucson, the coyotes eat them greedily, and their scat becomes as red as blood. Knowing that, it was not a surprise to learn of Oviedo's experience in the 1500s. Again, he wrote: "After one eats three or four of them (and better eating a larger number) if the one who has eaten them goes to urinate, the urine comes out exactly resembling true blood. And in this manner it happened to me the first time I ate them. And after an hour the urine began to flow (and the fruit greatly causes this) that when I saw the color of the urine I was astonished and frightened and greatly suspicious of my health."

Historically, Florida shared no species with Mexico, however, *O. stricta* var. *dillenii* is shared with the Caribbean. Bahamians call these plants scurgeon needle, and Puerto Ricans say *higo del mar* (sea fig). Elsewhere *O. stricta* is prickly pear (Florida, Jamaica, Virgin Islands, Barbados) or *tuna brava* (wild cactus), while it is bull sucker or miss blyden in the Virgin Islands. In Jamaica, it is seaside tuna. People in the French Antilles

say *cactier en raquette* (cactus with pads), *mal rachette* (bad pad, Dominica), *raquette* (pads, Hispaniola), *raquette à fleurs jaunes* (pads with yellow flowers, Guadeloupe, Martinique), *raquette à piquanats* (spiny pads, French Antilles), or *raquette bord de mer* (pads by the sea, French Antilles). The other indigenous name from the Caribbean is *bata* [pata] (Carib, Dominica). Mayan speakers in Yucatan call it either simply *pakan* [pak'an] (prickly pear) or *yaak-pak'an* [yaaxpakan, yax-pak'an] (ya'ax, green, pak'an, nopal). The latter name is used to distinguish it from *O. cochinillifera*.

In the southeastern United States, Harriot ([1590] 1972) said, "a kind of pleasant fruit almost of the shape and bigness of English peares, but that they are of a perfect red colour as well within as without." Harriot noted that in the West Indies the dye called cochineal grew, but he was not sure if it could be obtained from prickly pears in Virginia. That dye is from the cochineal insect *Dactylopius coccus*. DeBrahm ([1775] 1971) knew the plants and the dye source, and noted *Opuntia* in East Florida (the peninsula). Similarly, he and Romans ([1775] 1961) recommended the area for cochineal production because of the number of *Opuntia*. The Carolina Algonquians called the plant *metaqvesvnnavk* [metaquessunnauk, from *mā tahkwi-senyā-ki*, what is eaten bare or raw], given to *O. humifusa* in North Carolina (Harriot [1590] 1972, Geary 1955). That species is probably what the Biloxi called *maxon'tkxo'hi anaki*. The Osage said they were *tse'-wa-xa-ga ton-ga* (*tse'wa-xa-ga*, bison bur; cocklebur, *ton-ga*, big).

In Virginia, Strachey wrote in [1612] 1953 that the Powhatan called the leaf of the "prickle pear" *matakuskc* (Harrington 1955). Siebert (1975) wrote this phonetically as *matakask*, and said it was composed of /\*matw-/ , uneven, jagged, /\*ak-/ , capsule, nut, and /\*askw-i/, plant. He added that Algonquian speakers classify all fruits into /pak-/ , capsules, nuts, or /min-/ , berry, grain, legume. The root word is /pak-/ , shortened to /ak-/.

The Seminoles and Creeks know prickly pears and the de Soto chronicles mention them (De La Vega [1605] 1962). To them, the plants are *talakko* [tvrakko, tvrāko, twlakko, tvlhvcko] (*tlv* <etvlwv, tribe, *lakko*, large). Others have written the name *lakko* [rakko] (*lakko*, big, Muskogee), or *lakko* [kanrakkō] (*kan* <ekvvnv, land, *kanlakko* big, Creek). To the Miccosukee in Florida, it is *hacolkatō: nī* (Mikasuki). Other Muskogean names are *talaapā kha* [*tali aapakha*] (magic stone, Alabama) and the apparently cognate *talhpakha* (Choctaw), and *talipatká* (*tali*, stone, *pátka*, bed, Koasati).

Because of early references like Oveido, *Opuntia* is sometimes called cactus pear (Europe), Indian fig (USA, Europe), or even Barbary pear (Europe), although these names are usually applied to *O. ficusindica*, the species best known in Europe. *Opuntia ficus-indica* became popular early in the Old World (Jain and Tarafder 1970, Barbera et al. 1992, Brutsch and Zimmerman 1993). *Opuntia* became an important medicinal plant in China between the *Pen tsao kang mu* (Compendium of Chinese Medicinal Herbs) of 1590 and 1765 when the *Pen tsao kang mu shih* (Supplement to the Pen tsao kang mu) appeared (Hsu 1986).

Recent laboratory studies of several *Opuntia* species support Oveido's observation that the fruits (and other parts) are diuretic (Galati et al. 2002). In Mexico and the Caribbean, *O. stricta* is used to treat urinary problems, as a poultice and emollient for cuts, tumors, splinters, and boils and for stomach ulcers. Pads are heated and made into poultices to treat pleurisy and rheumatic pain. Other species are used as diuretics, against skin and eye inflammations, to halt diarrhea and dysentery, as a beverage for chest

problems and fever, as an analgesic, and to treat stomachache, high cholesterol, and diabetes (Martinez 1969, Morton 1981).

Laboratory experiments indicate that *Opuntia* remedies are effective as an analgesic (Loro et al. 1999), anti-inflammatory (Park et al. 1998, 2001, Loro et al. 1999), antiulcer (Galati et al. 2001, Lee et al. 2002), antifungal (Gupta and Banerjee 1972), and an antiviral agent (Ahmad et al. 1996). While *Opuntia* helps control diabetes (Meckes-Lozyoa et al. 1986, Frati-Munari et al. 1989a,b,c,d, 1991, 1992, RomanRamos et al. 1991, Trejo-Gonzalez et al. 1996, Bwititi et al. 2000, 2001, Shapiro and Gong 2002), some of the experiments also show toxicity to the kidney (Bwititi et al. 2000). Moreover, the plants help control cholesterol (Fernandez et al. 1990, 1992, 1994, Cardenas-Medellin et al. 1998) and act as antioxidants (Budinsky et al. 2001, Acuna et al. 2002), and monoamine oxidase B inhibitors (Han et al. 2001).

Most of the studies about *Opuntia* concentrated on action rather than chemistry. Still, the consensus is that the highly soluble fiber in the pectin decreases plasma low density lipoprotein concentration (Fernandez et al. 1990, 1992, Shapiro and Gong 2002), and is presumably responsible for several of the other actions. beta-Sitosterol is considered the anti-inflammatory component (Park et al. 2001), but the plants also contain triterpenes, malic acid, and succinic acid (Hsu 1986).

Chemical reports have concentrated mostly on nutritional value. The most abundant components of fruit pulp and skin are ethanol-soluble carbohydrates. Pulp contains glucose (35%) and fructose (29%) while the skin contains essentially glucose (21%). Protein content is 5.1% in the pulp, 8.3% in the skin, and 11.8% in the seeds. Starch is found in all parts of the fruit, with the pulp fibers rich in pectin (14.4%), and 29.1% cellulose in the skin and 45.1% in the seeds. The skin is remarkable for its content of calcium (2.09%) and potassium (3.4%) (El Kossori et al. 1998).

In addition to having the tasty and nutritious fruits mentioned by Oviedo and many others since (e.g., Saenz et al. 1998, El Kossori et al. 1998), the mucilaginous pads are edible raw or cooked. Young pads are usually cut into pieces and boiled, while mature pads may be roasted and eaten immediately or dried for future use. In Dominica and probably elsewhere the pads are used to wash the hair (Honychurch 1986). All aboveground parts of the plants are apparently effective medicines for a variety of problems. The plants host an insect that produces a dye that has been used for thousands of years by Mexicans and it was the source of "Royal Purple" for centuries (McJunkin 1991). Although cattle ranchers hate them, prickly pears are groceries and pharmacies hiding behind spines.

### *Orbexilium*

(Rafinesque coined this genus without explaining what it meant; perhaps from Latin *orbi*, a circle, and *exili*, thin, referring to the fruits)

***Orbexilium pedunculatum*.** From Britton and Brown 1897.

***Orbexilium pedunculatum*** (with flowers on a stalk) (= *Psoralea psoralioides*; *Orbexilium gracile*)

Bob's-root [bobsroot]; Congo root

Sampson's snakeroot (Samson or Sampson is the legendary Hebrew hero of great strength whose exploits are recounted in the Bible, Judges 13–15, but the individual named here is some other person, perhaps a black herbalist); snakeroot (used as a name for medicinal plants, but originally applied to either *Polygala senega* or *Aristolochia serpentaria*; later given to other plants)

scurf-pea ("scurf" has been a disease of the skin since about A.D. 1000 where scales or flakes of the epidermis continually fall; presumably, the name reflects the scaly morphological condition of the plant)

wi-ti-hi- warup?ha (root round, Catawba)

The concept of a snakeroot, or the root of a plant that counteracts the poison of snakes, appears to be of American origin. Europeans, however, were well versed in poisons, and firmly believed in counterpoisons. In Spanish counterpoisons were *contrayerbas*. Europeans were also familiar with poisonous snakes, having several species of *Vipera* (Viperidae) spread from England and Germany south. However, these "adders" were not as large or as toxic as those encountered in the New World (Ditmars 1931, Darlington 1957).

According to the records, the Seneca tribe of western New York taught the settlers to use American or Seneca snakeroot (*Polygala senega*) for snakebite. John Gerarde was among the first to record that Virginia snakeroot (*Aristolochia serpentaria*) was a potent counterpoison in 1633. No fewer than 13 species in 10 genera have been considered snakeroots during eastern North American history. The first record of Sampson's snakeroot seems to be from 1892 when that name was applied to *O. pedunculatum*.

Both Carolina's Catawba of the coastal plains and the Cherokee mountain people used these plants as medicines. The Catawba used a poultice or salve made from the roots to treat boils, wounds, sores, and broken bones (Speck 1934, Moerman 1998). The Cherokee used an infusion to induce abortions, as a diaphoretic against colic and indigestion, and as a tonic (Hamel and Chiltoskey 1975). There is no suggestion that

indigenous people used *O. pedunculatum* against snakebite, and perhaps Vogel (1970) was correct in suggesting that the original species called Sampson's snakeroot was *Gentiana catesbaei*. Indeed, it is under the latter scientific name that Porcher (1863) discussed the values of "Sampson's snakeroot" along with other *Gentiana*.

The use against snakebite must have come about because of African influence since the plants are commonly used in voodoo (Hocking 1997). That too must be the source of "Sampson" in the common name, and surely is for the name Congo root. Plant roots contain oleoresins that are used as an aromatic and bitter tonic and stimulant (McChesney and Adams 1985, Hocking 1997).

### *Orobanche*

(Named from Greek *orobus*, vetch, and *anchein*, to strangle, because several species specialize in growing on legumes)

***Orobanche uniflora*.** From Britton and Brown 1898.

*brincalheta* (from Latin *vinculu*, a confining band, alluding to the parasitic habit, Portuguese)

broom-rape (a translation of the Medieval Latin *rapum genistae*, meaning "a knob or tuber of *Genista*"; refers to the parasitic growths on the roots of broom or *Genista tinctoria*; the Latin was applied to *O. minor* by Rembert Dodoens in 1554 and translated into English in 1578)

*erba lupa* (wolf herb, Italian)

*fiamma* (flame, Italian)

*orobanche* (French)

*penachos* (from Italian *pennacchio*, plumed or beset with plumes, as feathers in hatbands, Portuguese)

*snylterot* (root parasite, Norwegian)

*Sommerwurz* (summer herb, German)

*succiamele* (from *succhione*, sucker, *miele*, honey, Italian)

***Orobanche uniflora*** (one-flowered)

[one-flowered] cancer-root (by 1546 there were references to herbs called “cancer” or “herbe cancer”; John Gerarde’s *Herball* of 1597 mentioned “cancerwort,” which apparently referred to *Linaria* or *Veronica*; however, “cancer-root” in association with plants seems to have appeared by 1714; see also *Conopholis*)

naked [pale] broomrape

pipes (Maine)

squaw-drops [squawdrops, squawroot] (North Carolina)

squirrel’s-grandfather (California)

The opinionated British Protestant clergyman William Turner wrote in 1548, “*Orobanche*...may of his properties be called Chokeweed, because it destroyeth and choketh the herbes that it tyeth, and claspeth with his roote.” That summed up European disgust for these parasitic herbs.

Europeans may have already known about medical uses of these plants when they arrived in the New World because a book on medicine published in 1671 said, “Broomrape...easeth pains in the Reins [kidneys].” Alternately, they may have learned uses from indigenous Americans.

Moerman (1998) found four or five species used for food and medicine among the Akimel O’odham (Pima), Blackfoot, Cahuilla, Gosiute, Keres, Montana, Navajo, Paiute, and Zuni. Among the medicinal uses were to treat wounds and sores, hemorrhoids, pneumonia and other lung troubles, cancer, and birth injuries.

No reference has been found that indigenous people in the southeastern United States used *Orobanche uniflora* or any other species. However, given the wide application by western tribes to external sores, wounds, and ulcers, southeastern use seems likely.

Porcher (1863) wrote that *O. uniflora* was “used as a remedy in carcinomatous affections, ulcers.” He also indicated, “Dr. [Benjamin Smith] Barton [1810] thought [both *O. uniflora* and *Epifagus* were] ingredients of a secret remedy for cancer, known as ‘Martin’s Cancer Powder.’”

Saadoun and Hameed (1999) found an antibacterial activity in the extract from *O. cernua*. That plant was effective against *Staphylococcus aureus*, *Streptococcus*, *Bacillus cereus*, and *Escherichia coll*. They wrote, “the *O. cernua* extract displays remarkable activity against some Gram-positive bacteria such as *Streptococcus* and *Staphylococcus*.”

***Orontium***

(According to Galen, Greek *orontion* was a name for a water-plant and remedy for jaundice; also the Syrian river called *Orontes*; Latin *Oronteus*, poetic for Syrian; one of Aeneas’s companions in the *Aeneid* was “ardent” Orontes; reapplied by Linnaeus to this American endemic)

***Orontium aquaticum*.** From Britton and Brown 1896.

***Orontium aquaticum*** (of wetlands, aquatic)

bog-torch (Georgia)

bull-tongue (a comparison with the leaf shape, Georgia)

fireleaf

floating arum

golden-club [goldenclub] (refers to the goldenyellow inflorescences; in use by 1860, USA)

never-wet [never-wets] (because submerged leaves resurface dry, Georgia)

*taw-kee* [*tackvim*, *tawkee*, *tawkin*] (Algonquian, in Delaware, New Jersey, Pennsylvania)

*tuckahoe* [*tockwhogh*, *tockawhough*] (by confusion, as this was historically used for *Peltandra*, Powhatan, Virginia)

water-dock (a resemblance of the leaves to *Rumex*)

The confusion between *tuckahoe* (*Peltandra*) and *taw-kee* (*Orontium*) may be due to faulty history, or it may have resulted from misunderstanding by Capt. John Smith. Perhaps, however, Fernald et al. (1958) were wrong when they wrote that the indigenous people used the two and their names indiscriminately. Neither the Swedes who learned from the local tribes nor Peter Kalm had any trouble telling the two apart.

When Kalm ([1753–1761] 1972) was in New Jersey in 1749, he discussed these wetland herbs with the settlers. They told him: “The *Indians* pluck the seeds, and keep them for eating. They cannot be eaten fresh or raw, but must be dried. The *Indians* were forced to boil them repeatedly in water, before they were fit for use; and then they ate them like pease. When the Swedes gave them butter and milk, they boiled or broiled the seeds in it. Sometimes they employ these seeds instead of bread; and they taste like pease. Some of the Swedes likewise ate them; and the old men among them told me, they liked this food better than any of the other plants which the *Indians* formerly made use of.” Core (1967) had the use correct, but he applied the wrong name.

Perhaps the indigenous people also ate the roots as they did *tuckahoe*. Yanovsky (1936) said that both roots and seeds were eaten by indigenous people in at least New

York, Pennsylvania, and Virginia, but that report is suspect. Their roots were eaten by settlers (Plowman 1969). Porcher (1863) wrote from hearsay, "The root is acrid, but becomes eatable by roasting." He implied that he knew firsthand that "both the seeds and roots were eaten by the Indians."

Cherokee babies were bathed in a decoction every new moon (Vogel 1970).

### *Osmanthus*

(From Greek *osme*, odor, and *anthos*, flower, because of the fragrant flowers)

*Osmanthus americanus*. From Sargent 1905.

#### *Osmanthus americanus* (American)

[American] devil-wood [devilwood] (a name in use by 1818; perhaps the name originated because of the hard wood)

[American, scrub wild, wild] olive (fruits resemble olives, *Olea europaea*, which are in the same family, Oleaceae)

Linnaeus named these trees *Olea americana* (American olive) in his *Mantissa Plantarum* of 1767. It was not until 1790 when Portuguese missionary Joao de Lourerio created the genus *Osmanthus* for Asian plants in the *Flora Cochinchinensis*. Almost a century passed before George Bentham and Joseph Hooker (Kew Gardens) realized that the American plants belonged in the Asian genus and created the modern name in 1878.

*Osmanthus* now contains 15 species, and grows in southern Asia and the southeastern United States. The genus has been incorrectly reported in Hawaii and Polynesia (Sargent 1905), but all Asian species grow from Russia to Japan and Taiwan (Fernald 1950, Ohwi 1965, Czerepanov 1994). Among the Asian species, *O. fragrans* is native to China where it has long been cultivated for its fragrant flowers that are used to perfume tea and confectionary (Hedrick 1919, Mabberley 1997).

*Osmanthus americanus* grows from Florida to eastern Louisiana where it reaches the Mississippi River, and east along the Coastal Plain to Cape Henry, Virginia (Fernald 1950, Radford et al. 1968, Jones and Coile 1988). *Osmanthus metacarpus*, the scrub wild olive, grows in the central Florida peninsula (Wunderlin 1998).

No records of indigenous people using the plants have been found. Moreover, there are few indications of other cultures using either *Osmanthus* species.

Conflicting reports of fruit edibility exist. In his *Flora Americana Septentrionalis* (Flora of North America) of 1814, Frederick Pursh said the fruit was edible. George Vasey, however, in a USDA report of 1875, disagreed. He said fruits were of no value (Hedrick 1919); however, they are oleaginous (Hocking 1997). Presumably, like the olive (*Olea europaea*), preparation of the drupes is necessary to make them edible. Neither Fernald et al. (1958) nor Tull (1999) mentions the species.

Wood from *Osmanthus* is heavy, hard, strong, resistant, difficult to work, dark brown, with thick light brown or yellow sap wood (Sargent 1905, Hocking 1997). Trees are uncommon, which is why use is only local. Bark from *Osmanthus* has been used as a bitter astringent, laxative, and emollient (Hocking 1997). However, the genus is absent from Porcher (1863), Vogel (1970), Foster and Duke (1990), Bremness (1994), Bown (1995), and Moerman (1998).

No chemical studies have been found for the American species. Asian species, on the other hand, have been examined by a number of laboratories. Some of the Old World species contain monoterpene alkaloids, essential oils, furanosides, glycosides (iridoid, lignan, phenolic, phenylethanoid, phenylpropanoid, and secoiridoid), pyranosides, verbascoside, and other chemicals (Inouye et al. 1975, Kaiser and Lamparsky 1978a,b,c, Kaiser et al. 1978, Wen et al. 1983, Inagaki et al. 1991, Sugiyama and Kikuchi 1991, 1993, Sugiyama et al. 1993a,b, Benkrief et al. 1998, Omura et al. 2000).

### *Osmunda*

(Origin uncertain, just as Linnaeus preferred; according to some, for *Osmunder*, the Saxon name for Norse Thor, the god of thunder, weather, and crops)

***Osmunda*.** *Osmunda cinnamomea* (left). *Osmunda regalis* (right). Both from Britton and Brown 1896.

***Osmunda cinnamomea*** (cinnamon-brown)

buckhorn brake [buckhorn fern] ("brake" perhaps of Scandinavian origin, akin to Old Swedish *braekne*, fern)

cinnamon fern (here and in the species name, the reference is to the reproductive fronds that are markedly different in color from the green sterile fronds)

fiddleheads (used for the ornamental carving at the bow of a vessel carved like the head of a violin; in use by 1599; applied to young fern leaves by 1882, perhaps earlier)

flowering fern (ferns are nonflowering plants, but the fertile fronds look like flower remnants to some)

***Osmunda regalis*** (royal)

bog onion (local name in the British Isles, alluding to the similarity of the caudex to an onion bulb)

buckhorn brake

flowering fern (used since at least the time of Porcher 1863)

*homockolo:píntapintí* [*hamótkólopintápinti*] (*hamockolo:p*, old paint woman, *im*, her, *tápinti*, fern, Mikasuki)

*helecho de espigas* (fern with spikes, Cuba)

*helecho real* (royal fern, Cuba); *raineach rioghail* [*righ-raineach*] (royal fern, Gaelic); royal fern (first in English by 1600; however, reference to royalty is much older in other languages); *kongsbregne* (king's fern, Norwegian); *KönigsRispenfarn* (King's panicle-fern, German)

*hoktalkoló: intocâ* (*hoktv*, old woman, *kolowv*, glue, *em*, her, *locowv*, clay jug, Creek)

Osmund royal (used by 1548, when written in English “Osmende royall”; apparently from Old Swedish *osmunder*, dating to 1350); Osmund the Waterman (from 1578, used by Rembert Dodoens in Dutch in 1554)

St. Christopher's herb (from 1578, used by Rembert Dodoens in Dutch in 1554)

water-fern (from 1578, used by Rembert Dodoens)

*yatcheiwashaguen taapente* [*yatahuwashat taapente*] (lost person's fern, Mikasuki)

Most sources simply say that *Osmunda* is probably derived from *Osmunder*, or *Thor* in Saxon. However, that oversimplifies what is known about the name. Cognates to “Osmund” go back to Medieval Latin *osmunda*, and French *osmunde* from the 12th century. In all of the English texts, the reference is to ferns, but not usually the plants now meant. Originally, the term “Osmund” indicated some of the “male-ferns,” including what is now *Dryopteris felix-mas*. It was not until the late 1600s or early 1700s that “royal fern” became fixed with *O. regalis*. Frenchman Charles Plumier was one of the first to use that concept in 1705.

Other options exist for derivation of the name *Osmunda*. One is Osmundus, an 11th-century Scandinavian writer. Another likely model is Osmun, Bishop of Salisbury, who died in 1099, and Quattrocchi (1999) implies that there are other possibilities. Regardless, all of these seem to postdate the legendary Osmunder and must be derived from that Scandinavian base.

Royal fern has a wide range, including both the Old and New Worlds. The plants grow from Newfoundland to Saskatchewan and south to Florida and Texas. They are also in Bermuda, the Bahamas, the West Indies, Mexico, and south to Paraguay. Europeans knew them when they arrived in the New World because they are in wetlands in Europe (from southern Norway south) and in western Asia to India and Korea (Morton 1981, Mabberley 1997). At least in northern Europe, there is a history of medical application of royal fern.

According to Vickery (1995), *O. regalis* is called both “royal fern” and “bog onion” in the British Isles. Up until at least the 1880s, it was still used to treat sprains, rheumatism, sciatica, and bruises. The caudex was beaten, covered with cold water, and allowed to “sit” overnight. The thick starchy fluid that resulted was used to bathe the affected areas.

Vickery (1995) also found a story about the ferns that I encountered among people in western Kentucky when I was growing up. Some British and Kentuckians believed that the fern “flowered,” but that it always did so at night. With daylight, the flowers disappeared, but we might know they had been there because they left their “seeds,” i.e., the spores.

People in the New World also took advantage of the royal fern. Hogan (1978) found *Osmunda* spores in the pre-Columbian samples she examined from the Fort Center site. The density in the coprolite samples led her to conclude that the people were using the ferns and that they were not contaminated by windborne spores.

We do not know how the Glades people used the ferns. The Seminoles used an infusion of the plant to steam and bathe the bodies of people who were “insane,” or disoriented (Sturtevant 1955). Modern Seminoles make a medicine from the roots to treat senility (Bennett 1997). A medicine was also made for use during childbirth and to treat chronically ill babies.

One application was to treat the malady called “Old Paint Woman’s Sickness” (Sturtevant 1955). That illness was caused by a supernatural being called *hamockolo:pi* (the old paint woman, Mikasuki). Her name is part of the Mikasuki word for royal fern that was, in the 1950s, *hamockolo:pintapinti* (*tapinti*, fern). To inflict her problems, she “hugs” the patient; the symptoms are weakness of the limbs and neck. A mixture of her fern with others is the remedy.

At least the Iroquois and Menomini also used this fern (King 1984, Moerman 1998). The Iroquois mixed fronds of royal fern with wild ginger to expel worms from children. They also made a remedy for blood and menstrual problems, and kidney ailments. The Menomini used the roots in a medicine to promote lactation.

During the Civil War, Porcher (1853) wrote of royal fern: “It is sometimes employed in dropsy, as an astringent in injuries, and by Dr. Heidenreich in the radical cure of hernia...it purges mildly in doses of two to four drachms of the powder. It acts upon the bile, augments digestion, and strengthens chylicification. The extract has been thought peculiarly suited to cases of children affected with caries, mixed in milk or water, and continued for some time...has been employed successfully in doses of three drachms in the rickets.... The leaves have been selected to make cradles for delicate children, from some supposed good effects derived from their use.”

*Osmunda cinnamomea* is less common in the area around Lake Okeechobee where Hogan (1978) studied the Fort Center Glades site, but it becomes more common farther into the temperate zones. The Koasati in Louisiana used *O. cinnamomea* as a medicine

(Taylor 1940). The Cherokee of the Carolinas used a decoction to treat rheumatism and chills (Hamel and Chiltoskey 1975). The Iroquois used a decoction to relieve headache and rheumatism pains, colds, and menstrual problems (Moerman 1998). The Menomini ate the young leaves and made a medicine to increase milk flow (Yanovsky 1936).

Several tribes knew that the young, incompletely unfurled leaves were edible (Moerman 1998). The Abenaki ate them as a snack, and the Menomini added them to soup. The Menomini also figured that eating the young leaves would make them smell like deer that had been browsing on the plants, and perhaps make it easier to approach the deer. Fernald et al. (1958) wrote that croziers were eaten by small boys but not appreciated by adults. They do tend to have a bitterish flavor that most people of European lineage do not like.

### *Ostrya*

(The Greek name for a tree with hard wood; Theophrastus, 372–287 B.C., was probably talking about the southern European *O. carpinifolia*)

*Ostrya virginiana*. From Sargent 1905.

*carpinella* (Italian)

*charme houblon* (hop hornbeam, French)

*Hopfenbuche* (hop bush, German)

*Ostrya virginiana* (of Virginia)

American hornbeam (“hornbeam,” the name of a European species from the 1570s or before, because of its hard, tough, close-grained wood; originally used for *Carpinus*)

*bois de fer* (ironwood, Quebec)

deerwood (probably in the sense of a “wood” or woodland where deer are likely to be found)

hardhock (maybe from “hock,” derived from “hook”; a rod or stick with a hook at the end, used since 1570; perhaps related to the name “hardback” used locally in New England for *Spiraea tomentosa*)

[eastern, woolly American] hop-hornbeam (“hop” used as modifier because of the similarity of the fruit cluster to that of the hop, *Humulus lupulus*; used by 1794)

ironwood (name given, often locally, to various trees with extremely hard wood; dating from at least as early as the 1650s)

*ittowanha* (*itto*, tree, *wanha*, hard, Alabama); *itukawiloha* [*itukahiloha*] (Choctaw)

leverwood (“lever” is a bar used to dislodge some heavy or firmly fixed object)

*mananous* (Ojibwa)

Southern Europeans knew hop-hornbeam (*Ostrya carpinifolia*) when they arrived in the New World. The new one they found was *O. virginiana*. Wood from the New World species was much like that in the Old World. It is strong, hard, tough, durable, light brown tinged with red or often nearly white, with thick pale sapwood (Sargent 1905). Both the Lakota and the Malecite used the wood to make bows (Moerman 1998). Probably other tribes used it similarly. The Ojibwa used the trunks to build dwellings (King 1984). Among people of European heritage the wood has been used for fence posts, golf clubs, tool handles, mallets, and woodenware (Vines 1977).

The Cherokee, Delaware, Iroquois, Ojibwa, and Potawatomi made medicines from *Ostrya* (Smith 1933, King 1984, Moerman 1998). Bark decoctions were used to build up the blood, soothe sore muscles, and relieve toothache by the Cherokees (Hamel and Chiltoskey 1975). The Delaware used a root mixture for female problems and as a tonic. The Iroquois made decoctions to treat cancer, coughs, swellings, and tuberculosis. The Ojibwa made medicines to treat coughs, lung hemorrhages, urinary problems, and rheumatism. The Potawatomi used the bark to stop diarrhea and hemorrhages.

### *Oxydendrum*

(From the Greek *oxys*, sour, and *dendron*, tree, because of the acidic foliage)

***Oxydendrum arboreum*.** From Sargent 1905.

***Oxydendrum arboreum*** (becoming a tree)

*arbre oseille* [*arbre l'oselle*] (sorrel tree, French); sorrel-tree (“sorrel” from *surelle*, diminutive of French *sur*; “sorrel-tree” used in 1730 by Mark Catesby; in 1856 Asa Gray equated it with “sourwood”)

arrow-wood (a name widely applied to many genera because of the straight young stems that were made into arrow shafts)

elk-tree (“elk” is of uncertain history, but probably derived from Latin *alces* and Greek *alee*, both referring to the European Cervid, *A Ices alces*,

the animal known in North America as “moose”; later applied also to wapiti or *Cervus canadensis*; presumably, the common name alludes to the leaves being favored as food)

*iti kosoma* (*iti*, tree, *kosoma*, fetid, Choctaw)

lily-of-the-valley-tree (an allusion to the small white flowers that are reminiscent of those on lily-of-the-valley, *Convallaria*)

*pin-ne-se-ga* (astringent taste, Osage)

*Sauerbaum* (sour tree, German); sourwood (“sour” derives from Old English *sūr*, with cognates in French *sur*, German *sauer*, Dutch *zuur*; used by 1856 where equated with sorrel tree by Asa Gray); sour gum [sourgum-bush]

titi (etymology uncertain, maybe from “tie”; the local use in northern Florida implies that it came about because of the difficulty in passing through the vegetation consisting of these plants, hence local names such as “Titi Hell”; originally applied to members of Cyrillaceae by 1860; J.K. Small linked the name with *Oxydendrum* in 1903; or could it be from Choctaw *iti*, tree?)

*ʔyápske*[*yap hitaʔare*](tree sour, Catawba)

When Catesby, Gronovius, and Linnaeus were confronted with the trees now known as *Oxydendrum*, they did not know what to do with them. Catesby called them *Frutex foliis oblongis acuminatis* (shrub with oblong acuminate leaves). Gronovius did not do much better with *Andromeda arborea, foliis oblongoovatis integerrimis* (Tree *Andromeda* with oblongovate, entire leaves). Linnaeus used the Gronovius name and called them *Andromeda arborea*.

The plants they put them with, *Andromeda*, are small shrubby members of the Ericaceae. Both *Andromeda* species grow in the Northern Hemisphere with one widespread in Europe. Finding a tree form of these did not seem to bother Linnaeus because his concept of *Andromeda* was much broader than that used today. It was not until Augustin-Pyramus de Candolle studied the plants for his *Prodromus* of the world flora that the genus *Oxydendrum* was created in 1839. The single species is confined to the deciduous forests of eastern North America, ranging from Pennsylvania and West Virginia west to Ohio and Indiana, and south to Florida and Louisiana (Fernald 1950). *Oxydendrum* has been reported from Texas, but Correll and Johnston (1970) could not verify its presence there.

Although Hamel and Chiltoskey (1975) say that sourwood was used for firewood by the Cherokee, that was not always the case. Indeed, Mooney (1885–1886) said that his informants told him that wood from the tree was never burned. They believed that lye made from the ashes would “bring sickness to those who use it in preparing their food.” They also maintained that, if a person slept beside a sourwood fire, the wood “will barbeque him.”

However, these taboos did not prevent the Cherokee from using branches of sourwood to cook their meat before the fire. It was a preferred cooking wood because its acidic flavor gave the meat a better taste (Mooney 1885–1886). Spoons and combs were also carved from the wood. Other uses among the Cherokee were to make sled runners, arrowshafts, and pipe stems (Hamel and Chiltoskey 1975).

Yanovsky (1936) said that the young leaves were eaten in salads in the southeastern states. This is one of several places where he extrapolates too far. South-eastern tribes normally did not eat raw vegetables (Hudson 1976).

Both the Catawba and the Cherokee used sourwood in medicine (Moerman 1998). The Catawba used an infusion as a menstrual aid and for women

*Oxypolis filiformis*. From Institute of Food and Agricultural Sciences.

undergoing menopause. The Cherokee used the plant in an infusion to stop diarrhea and as a tonic for indigestion, nervousness, asthma, and spitting blood (Hamel and Chiltoskey 1975). Bark sap was used on itch, and the bark was chewed to heal mouth ulcers.

Settlers continued using the plants as medicine. Porcher (1863) wrote: "The leaves, when chewed, allay thirst. A decoction of the bark and leaves is also given as a tonic." Foster and Duke (1990) noted that "Leaf tea [is] a Kentucky folk remedy for kidney and bladder ailments (diuretic), fevers, diarrhea, and dysentery."

*Oxypolis*

(Named by Rafinesque in 1825, from Greek *oxys*, sharp and *polos*, axis, referring to the leaves)

*Oxypolis filiformis* (threadlike, another reference to the leaves)

*akkolo:tka* [*akkolo:rkd*] (*akkolo:tka* is usually *Nelumbo*, Creek; a comparison or a misuse)

*caḡā:mā:bî* (*a:bi*, replica, Mikasuki)

water dropwort (Florida, Bahamas)

Thomas Walter described *Oenanthe filiformis* in 1788 based on specimens from South Carolina. It was not until 1894 that N.L. Britton moved the species to *Oxypolis*. There are now seven species in this endemic North American genus (Mabberley 1997).

There are records of two species having been used. The Cherokee used *O. rigidior*, stiff cowbane, roots for food (Hamel and Chiltoskey 1975). The Seminoles had names for *O. filiformis* but they remembered no uses (Sturtevant 1955).

# P

## *Packera/Senecio*

(*Packera*: Named in 1976 by Askell and Doris B.M. Löve for Canadian botanist John G.Packer; *Senecio*: From Latin *senex*, an old man, alluding to the white pubescence of many species, or the white pappus)

***Packera aurea*.** a. Plant in flower, b. Ray flower, c. **Disk** flower, d. Longitudinal section, e. Seed. From Buchholtz 1968.

*åkersvineblom* (field-wine-bloom, *Senecio vulgaris*, Norwegian)

*bualan* [*am bualan*] (Gaelic)

*cardo morto* (dead thistle, *S. vulgaris*, Portuguese)

*erba calderugia* (bowl herb, maybe from the resemblance of the involucre to a bowl or volcanic caldera, *S. vulgaris*, Italian)

*gemeines Kreuzkraut* (common cross-herb, *S. vulgaris*, German)

*Greiskraut* (gray [aged] herb, German)

groundsel (derived about A.D. 700 from AngloSaxon *grundeswelgiae*, pus-absorber; perhaps, but less convincingly, from *grundeswylige*, ground-absorber, because of its rapid spread)

*herba cana* (white-haired herb, *S. vulgaris*, Spanish)

*lus Phara léith* (gray-headed Patrick's herb, Gaelic)

ragweeds (a name applied to *Senecio* since ca. 1658, and expanded to *Ambrosia* ca. 1866)

ragwort (probably applied because of the ragged leaves; used in English by A.D. 1450; applied at least by John Gerarde in 1597 to St. James wort, *S. Jacobaea*)

*sciopeti* (Venetian dialect for "little exploders" because you can take the bracteal cup and hit the back of your hand and it will make a noise like a little explosion, Italian)

*séneçon* (old one, French); *suzón* (*S. vulgaris*, Spanish)

*tasneirinha* (diminutive of *tasneira* or *taneceto*, from *Tanacetum*, alluding to the resemblance between that member of the Asteraceae and *S. vulgaris*, Portuguese)

***Packera anonyma*** (nameless) (= *Senecio anonymus*)

Small's ragwort (Nathaniel L. Britton tried to name this species *S. smallii*, for John K. Small, but he proposed that name in 1890, and Alphonse W. Wood had already named the plant in 1861)

***Packera aurea*** (golden) (= *Senecio aureus*)

butter weed (unexplained by Williams [1837] 1962; perhaps for the butter-yellow flowers)

false valerian (the name alludes to *Valeriana*, a widely used medicinal herb)

female regulator (alluding to use in controlling fertility or use during childbirth?)

fireweed (usually given to Onagraceae, formerly *Epilobium*, and to Asteraceae, *Erechtites*)

golden ragwort

golden senecio (book name)

*Goldenes Kreuzkraut* (golden cross-herb, German)

*hanatcuwi' hare* (make [child] come quick, Catawba)

life-root [liferoor]; life-wort [lifewort]

squaw-weed ("squaw" from the Narragansett *squaws*, Massachusetts *squa*, woman, with related forms in other Algonquian languages; combined with "weed" by 1847 by Darlington who wrote that it "had been denounced...as being poisonous to sheep")

unkun (English? a name unexplained by Millspaugh 1892)

When Wunderlin (1998) published his *Guide to the Vascular Plants of Florida*, he used the long-established genus *Senecio*, based on the Latin name of a plant used by Pliny. The name alludes to the white pubescence of many species or to the white hairs of the pappus. Later, Wunderlin and Hanson (2002) accepted several changes in the genera of Asteraceae and began using the genus *Packera* for a group of 60 to 65 species, mostly in North America, with 16 in Mexico, and others in Siberia. Kartesz (1994) continued using *Senecio* in the broad sense, so both options are given here.

Regardless of the name, the species contain potent pyrrolizidine alkaloids (e.g., senecionine), which cause liver damage if ingested (Lewis and Elvin-Lewis 1977, Lampe and McCann 1985). That damage occurs through acute venous occlusions in the liver (BuddChiari syndrome), and can lead to cirrhosis and, in some cases, death (Lampe and McCann 1985, Foster and Duke 1990).

In spite of their toxic properties, some species were still being used externally in Europe in the 1970s as poultices for wounds and abscesses (OED 1971). Bown (1995) found that *P. aurea* still is grown in Belorussia, central Russia, and the Ukraine for the pharmaceutical industry.

Plants in this group of Asteraceae have been used by people for thousands of years in both hemispheres. Famous species in Europe are *S. cineraria*, *S. jacobaea*, and *S. vulgaris* (Polunin 1969). Vickery (1995) found people still applying *S. vulgaris* to cuts, treating ague with it, and using it as a laxative. *Senecio jacobaea* was associated with witches and fairies in the British Isles and is known in Gaelic as *buadhghallan buidhe* [*buaghallan*, *bohòlàun*, *bohòlàun buidhe*] (*buadh*, virtuous, *ghallan*, branch, *buidhe*, yellow).

In the Americas, the Catawba used *P. anonyma* to treat consumption (Moerman 1998). The Cherokee used *P. aurea* as a contraceptive and for heart trouble (Hamel and Chiltoskey 1975). The Iroquois used *P. aureus* for the blood, as a diaphoretic, to reduce fever in children, and to treat broken bones (Moerman 1998).

Porcher (1863) wrote, "It is said by [David] Schoepf to have been a favorite vulnerary with the Indians; the juice of the plant in honey, or the seeds in substance, are employed." Millspaugh (1892) knew that the plants had been used by indigenous people to stop bleeding, as an abortivant, and a vulnerary. It was recommended for controlling bleeding in the lungs, for uterine problems, as a diuretic, pectoral, diaphoretic, and tonic.

Bown (1995) still maintained that *P. aurea* is a bitter, astringent herb that is diuretic, stimulates the uterus, and controls bleeding. However, she added that it should be used by "qualified practitioners only," and that it is subject to legal restrictions in some countries. Duke et al. (2002), who typically give levelheaded recommendations, list *P. aurea* as "XXX"—not to be used (think of each X "as a skull and crossbones"). Hocking (1997) noted that *P. anonyma* has been said to have antitumor properties, but gives no reference.

Moerman (1998) found ten other species of *Senecio* and *Packera* being used by different tribes within North America. Thus, it would be surprising if other species (*P. glabella*, *P. obovata*, and *P. paupercula*) had not been used by indigenous tribes. However, of these, *R glabella* has an enormous range in North America and no records have been found of anyone using it.

***Panicum***

(From the classical Latin name of bread, *panis*, or millet, *panus*; related to Akkadian *panu*, Italian *pane*, bread)

cockspur (originally the spur on a cock or male chicken, used since at least the 1590s; awns on some grasses led to the comparison with the fowl)

*Hirse* (German)

*millet* (from Latin *millium*, having a thousand grains, French); *miglio* (Italian); *milho* (Portuguese)

***Panicum hemitomom*** (halved, from the somewhat one-sided spikes)

*cintha:câ:bî* (snake tail replica, Mikasuki); *cintha:cî* (snake tail, Mikasuki)
